FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April to 30th November.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 31st October, 1935	No. Eggs Laid Month of November, 1935.	Total Eggs Laid 1st April, 1935, to 30th November, 1935.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF MURRAY LANDS EAST BRANCHES.

A strong north wind, accompanied with a severe dust storm, prevented many delegates from distant Branches from attending the Conference of Eastern Murray Lands Bureaux, which was held at Alawoona on 1st October. Mr. Wm. Paull (Alawoona) presided, the opening address being delivered by Mr. A. J. A. Koch (Member of the Advisory Board of Agriculture).

“The Changed Economic Value of Mallee Lands” was the subject of a paper presented by Mr. T B. Flint, of Alawoona. Mr. G. A. Thompson (Alawoona) contributed a paper, “Silage and Side Lines.”

Conference carried the following resolutions:—“That the 1936 Conference be held at Alawoona”; “That the Government be asked to take steps to control the fox menace by proclaiming destruction periods prior to lambing, and it is suggested that scalps be paid for to encourage destruction”; “That this Conference considers that no scheme of debt adjustment will be acceptable or practicable unless security of tenure and a payable price for wheat are guaranteed, and that all revaluations and investigations are carried out by practical men who are farmers”; “That in view of the valuable information obtained by Mr. Spafford during his trip overseas, this Conference asks the Government to send at least one officer of the Department abroad each year.”

At the evening session Mr. W. J. Spafford (Deputy Director of Agriculture) gave an address illustrated with lantern views on his trip overseas.

CONFERENCES OF EYRE'S PENINSULA BRANCHES.

Branches of the Agricultural Bureau in the Eastern, Lower, and Central districts of Eyre's Peninsula held Conferences at Butler, Yeelanna, and Wudinna respectively on 8th, 16th, and 18th October. Each Conference was attended by Messrs. W. J. Spafford (Deputy Director of Agriculture) and H. C. Pritchard (General Secretary). Messrs. H. B. Barlow (Chief Dairy Instructor) and H. D. Adams (Agricultural Instructor) were present at Butler and Yeelanna; Mr. S. Shepherd (Advisory Board of Agriculture) at Yeelanna and Wudinna; Mr. C. A. Goddard (Assistant Wool Instructor, School of Mines) at Yeelanna; and Mr. W. H. Brownrigg (Agricultural Instructor) at Wudinna.

Mr. Spafford gave an address (illustrated with lantern views) at the evening session of each Conference on “A Trip Through the Southern Hemisphere.”

Butler Conference.

Mr. H. Tilley presided over the Butler Conference, which was formally opened by Mr. Spafford. The following papers were read by members:—“Fodder Conservation on the Farm,” Mr. C. F. Jericho, Butler; “Wheat Farming *versus* Sheep,” Mr. J. Crooks, Taragoro; “Breeding Fat Lambs on Eyre's Peninsula,” Mr. E. J. Barraud, Lipson; “Some Suggestions for Eyre's Peninsula Farmers,” Mr. F. Masters, Verran; “The Advantages of Crop Competitions,” Mr. N. G. Stewart, Butler.

The General Secretary undertook to make further inquiries into complaints that the quantity of superphosphate supplied by the Farmers' Assistance Board was not in accordance with that recommended by the Agricultural Instructors.

Resolutions carried were:—"That the attention of the Port Lincoln District Council be drawn to the spread of St. John's Wort, and that early steps be taken for the eradication of this weed"; "That the Port Lincoln Bacon Factory be asked to purchase pigs at live-weight on the hoof, as is done by some other firms in this State; "That the next Conference be held at Kimba."

Yeelanna Conference.

The Conference at Yeelanna was opened by Mr. S. Shepherd, and Mr. L. E. Clarkson presided. Papers were given by Mr. J. H. Vigar, Mount Hope, on "Tree Culture on the Farm"; Mr. A. Doley, Yeelanna, "The Problem of Soil Erosion"; Mr. J. Carter, Koppio, "Can a Profit over Expenditure be Obtained in Growing Feed, especially for the Production of Wool at 1s. per pound?"; Mr. R. W. Pearson, Yeelanna, "Farm Book-keeping"; Mr. R. Schultz, Koppio, "Preparing Beeswax for Comb Foundations"; Mr. Ray Proctor, Yeelanna, "Preparing Land for Seeding."

The following resolutions were carried:—"That a stock inspector be stationed on Lower Eyre's Peninsula, with the object of eradicating lice and tick from sheep"; "That this Conference forward a resolution to the Government that in future lamb seasons the Port Lincoln Freezing Works provide means of treating more lambs daily than they are accommodating this season"; "That more information concerning the ultimate disposal of resolutions submitted to Conference be forwarded to Conference Branches after such resolutions have been disposed of"; "That the next Conference be held at Yeelanna."

A visit was made to the farm of Mr. R. R. Wilson in order to inspect the experimental plots and dairy stock. Mr. Barlow gave an address on points of a dairy cow, using Mr. Wilson's stock for demonstrating his remarks.

Wudinna Conference.

Mr. A. W. H. Barnes was Chairman of the Wudinna Conference, and Mr. S. Shepherd delivered the opening address.

Mr. C. Johns, Wudinna, read a paper on "Some Aspects in the Bulk Handling of Wheat"; Mr. O. J. Murphy, Warramboo, "Treatment of Fallow"; Mr. Max O'Brien, Wudinna, "Management of the Farm Flock"; Mr. C. H. Edmonds, Pygery, "Could the System of Farming, as practised in this district, be reviewed."

Resolutions were:—"That a further 50 per cent. concession on present freight charges on sires of farm stock be allowed by the Government"; "That a market for fat stock be established at Port Lincoln, to be worked on the same lines as the abattoirs, in conjunction with the Port Lincoln Freezing Works"; "That the acreage wheat bounty be the same as last year, and the bushel bounty be pooled in order to provide the same price at country sidings as first-class sea ports"; "That the Advisory Board send a circular to farmers in the Central Conference District, asking them to endeavour to have export lambs ready by 1st September each year"; "That this district be proclaimed a compulsory dipping area"; "That this Conference is in favour of bulk handling of wheat, preferably on the system adopted in Western Australia"; "That no low grade milling wheat be eligible for competitions, and that the Advisory Board be requested to use its influence to eliminate the growth of low grade milling wheats"; "That the next Conference be held at Minnipa."

FRUIT GROWERS CONFERENCE AT LYNDOCH.

Branches of the Agricultural Bureau whose activities are devoted to fruit growing in the non-irrigated districts of the State, met in conference at Lyndoch on 5th November, delegates being present from Light's Pass, Greenock, McLaren Flat, Blackwood, Williamstown, and Lyndoch.

Mr. E. N. Evans (Lyndoch) presided and Mr. W. J. Spafford (Deputy Director of Agriculture) delivered the opening address, in the course of which he drew attention to the great horticultural potentialities of some of the countries that he had visited during his tour of the Southern Hemisphere.

The competition that would inevitably come from these countries when their orchards and vineyards were in full bearing, he believed could only be met by Australia exporting produce of the best quality.

Mr. J. S. Hammat (Lyndoch) read a paper on ''Some Observations of the Control of Codlin Moth,'' and Mr. B. Boehn (Light's Pass) contributed an excellent paper on ''Manuring Vines.''

The following resolutions were carried:—

> ''That growers get into touch with their district instructors with a view to having further investigations made into die-back of apple trees.
>
> ''That a greater sum be paid to the Fruit Industry Sugar Concession Committee in order to stabilise the fruit industry.''
>
> ''That a viticultural instructor be appointed for the non-irrigated vine growing areas.''
>
> ''That an experimental orchard and vineyard be established in connection with the Nuriootpa High School.''
>
> ''That a geological survey of the district be made in connection with water for irrigation and prevalence of frost.''

It was decided that the decision as to the place of the 1936 Conference should be left in the hands of the Advisory Board.

Through the courtesy of Messrs. G. Gramp & Sons Ltd., delegates to the Conference were afforded the opportunity of inspecting the Orlando Wine Cellars.

The evening session was occupied with an address, ''A Trip Through the Southern Hemisphere,'' illustrated with lantern slides, delivered by Mr. Spafford.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, 27th November, 1935, there being present Messrs. A. L. McEwin (Chairman), H. N. Wicks, F. Coleman, Geo. Jeffrey, A. M. Dawkins, Dr. A. E. V. Richardson, and H. C. Pritchard (Secretary).

Apologies were received from Messrs. J. B. Murdoch, A. J. A. Koch, P. J. Baily, S. Shepherd, and Professor A. J. Perkins.

New Members.—Approval was given to the addition of the following names to the rolls of existing Branches:—Balhannah Women's—Miss D. Robinson, Miss Morris; Bundaleer Springs—G. Seal, J. Rundle; Caliph—F. Richards; Chandada—Martin Dreckow, P. A. H. Danenberg, O. C. Danenberg, John Horsell, R. J. Evans; Chilpuddie Rock— — McMahon; Coonalpuna—M. Hissey, N. Mincham, F. McMahon; Echunga—A. J. Feder, Arthur Hampton; Eurelia Women's—Mrs. C. Dowd, Mrs. F. Stainer, Mrs. A. G. Polden, Mrs. J. Polden, Mrs. C. Phillis; Frayville—H. A. Krause; Gladstone Women's—Mrs. L. O. Robertson; Hilltown—L. J. Ashton, J. Humphries; South Kilkerran—H. Zacher; Kybybolite Women's—Mrs J. Lester, Mrs. H E. Wilkes, Miss E. M. Wilkinson; Lameroo—G. Morris, H. M. Morris, H. J. Blake; Lone Gum and Monash—W. Carter, L. Stratman, G T. Evans, G. J. H. Smith; Millicent Women's—Mrs. E. C. Hutchesson, Mrs J. Allen; Morchard- H. Brown; Morchard Women's—Mrs. L. Wilks, Mrs. L. Nottle, Miss I Pitchers, Mrs. C. Halliday (jun), Miss J. Irvine; Mount Bryan—A. Schenscher, T. P. Griffin, H. Griffin, C. Rawlins, J. Hooper, E. C. Collins, E. A. Blight, C. Seebohm; Mount Compass—David Black, Eric Webster, — Jurgins; Mount Pleasant—J. H. Buckley, D. Buckley, P. B. Haeusler, H McD. Verrall, G. A. Deane, Phil. Chapman, L. F. Rollond; Mudamuckla Women's—M. S. M. Stasinowsky; Murray Bridge—Frank W. Hambridge; Murraytown—R. A Tregenza, H. R. Phillis; Mypolonga—L. Lace, P. H. Pickering; Roseworthy—F. Bammann; Sheaoak Log Women's—Mrs W. Both; Strathalbyn—George Semple; Truro—R. Schliebs, F. E Winton; Ungarra—J. R. Schramm, G. Lawrie, A. Lawrie, A Brechin, J. Duffield, W. G. Gordon, J. Gordon, J. G. Jericho; Warcowie Women's—Miss E. H. Telfer; Wasleys Women's—Mrs. R. Duffield; Watervale—R. J. Graham, K. Nicoli; Williamstown—W. R. Parmenter, D. Manser, F. E. Rix, H. J. Spencer, E. Gottwald, W. C. Smith, A. Bain, C. G. Fromm, A. T. Leske, Sid. Coleman, F. Gangel; Willowie—R. A. Barrie; Wirrabara—T. Cockburn, D. Milne, O Jaeschke, G. Stevens.

Members of New Branches.—Devlin's Pound -A. G. Robertson, G. O. Roxall, C. R. Smith, H. A. Loffler, A. W. Neindorf, John Chesney, R. A. Loffler, R. Zehender, G. A. Chesney, T. A. Cain, Jack Loffler, Max Hunger, R. K. Albrecht, K G. Albrecht, S. A. Pickering, J. E. Pickering, O. A. Peterson, T. J. Cain, W. Hammerling, O. P. Muehlberg, F. W. Huesler; Devlin's Pound Women's—Mrs. C. Smith, Mrs. J. L Loffler, Mrs. Zehender, Mrs. — Loffler, Miss J. Smith, Miss R. Koop, Mrs. G. Chesney, Mrs. H. A. Loffler, Miss E. Glastonbury, Mrs. S. Pickering, Mrs. W. Huesler, Mrs. E. Doig, Miss D. Doig, Miss E. Peters.

Life Members.—Approval was given to the addition of the name of Mr. C. B. Pope (Mount Barker) to the roll of Life Members of the Agricultural Bureau.

Minnipa Farm.—The Minister intimated that he had dealt with the re opening of the Minnipa Farm as a seed wheat station with the Director of Agriculture, and stated that the question of re-starting the Experimental Farm would be considered in April, 1936.

Soil Erosion.—The Secretary reported that the Director, Local Government Department, had sent a circular to all district councils drawing attention to Congress resolution recommending conserving and planting trees. The Director pointed out that the area of reserves and roadsides under councils' control was considerable, and that the Minister urged on councils the necessity for safeguarding trees and native shrubs in such locations, and of inaugurating a system of tree planting wherever conditions were suitable. Received.

St. John's Wort (Butler Conference).—The district clerk at Port Lincoln intimated, in response to a resolution of the Butler Conference, forwarded through the Board, that notice had been served on landholders to destroy St. John's Wort on their property, and that further action would be taken to have the weed eradicated.

Duty on Wire Netting (Congress Resolution).—"That Congress urge the Federal Government to remove the duty from imported wire netting or substantially reduce same." The Secretary reported the present duty was 200s. general tariff; British preferential tariff, free; primage and sales tax, nil. Decided to advise Branches accordingly.

Sheep Dipping (Wudinna Conference).—"That this district be proclaimed a compulsory dipping area." Koppio Branch.—"That this Branch request the Stock and Brands Department to station a permanent stock inspector on Eyre's Peninsula to check breaches of the Brands Act, and to take action for the eradication of lice and tick in sheep." Yeelanna Conference.—"That a stock inspector be stationed at Lower Eyre's Peninsula with the object of eradicating lice and tick from wool." Decided to forward the resolutions on to the Minister with the support of the Board.

Die-back of Apple Trees (Fruitgrowers' Conference at Lyndoch).—"That growers get into touch with their district instructors with a view to having further investigations made into die back of apple trees." Decided to inform Branches accordingly.

Foxes (Murray Lands (East) Conference).—"That the Government be asked to take steps to control the fox menace by proclaiming destruction periods prior to lambing, and that it is suggested that scalps be paid for to encourage destruction." The Secretary reported he had approached the vermin board department, which stated that the Act provided for simultaneous destruction of vermin. The term "vermin" included foxes. The periods for simultaneous destruction in the Brown's Well district council and other councils in that direction were 1st to 14th March and 1st to 14th August. There was no "scalp" money for foxes. Decided to advise the Branches concerned accordingly.

Young People's Employment Council.—Dr. Richardson reported he had attended two meetings of the Young People's Employment Council when the three following resolutions were carried:—(1) "This Conference recommends that a survey be made on the absorptive capacity for employment in existing industries, and the potential scope for the development of new industries." (2) "This Conference considers that more encouragement should be given to boys to give preference for agricultural pursuits, and that the Government be asked to investigate the possibilities for closer settlement in regions of assured rainfall." (3) "This Conference is of the opinion that family land settlement provides the best means of rehabilitating unemployed married persons and their families." Dr. Richardson was thanked for his interest and attendance at these meetings.

Several items were taken in Committee.

ESA BLUESTONE

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on 2nd December, 1935:—

BUTTER.—The tonnage of butter manufactured during November was well maintained, and in the aggregate was 25 per cent. to 30 per cent. greater than for the corresponding period last year. This result was largely due to the fact that the weather was congenial throughout, and except for a day or two of warm weather now and again conditions were cool. Trade in print butters was well maintained in the metropolitan area, and regular shipments of butter in bulk were made to Britain. Market fluctuations there were acute, and after the upward trend came back rather suddenly. At moment values for Australian choicest on spot are 97s to 98s. per cwt., and local rates are:—Choicest creamery fresh butter. in bulk, 1s. 3¼d. per lb. Prints and delivery extra. (This price is for local sale only and, under the quota system the equalised price manufacturers will receive will be 12.09375d. per lb. on which basis payments to cream suppliers will be calculated.) Separator lines from 10½d. to 11½d. per lb for choicest; stores, 6d. to 8d. per lb. (These prices are subject to equalisation levies.)

CHEESE.—This commodity also has been manufactured in record quantities this season, and apart from the local and Western Australian trade heavy shipments were made to London and other ports of Britain, and the South Australian cheese is meeting with favour in these markets. Local rates are:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. 1d. to 1s. 1½d. per lb.

EGGS.—Many difficulties were encountered in connection with egg exports this season, and very stringent conditions were imposed by the Commonwealth authorities so that the quantities shipped overseas will be very much less this year. Consequently, a greater proportion of the supplies have been manufactured into egg pulp, and market is weak at:—Ordinary country eggs, fair average quality, from 3½d. per doz. net; long distance rail or shipping eggs, lower; selected new laid, clean eggs, full sized, 7½d. to 8d. per doz. net.

BACON.—With the general warm weather conditions the consumption of bacon was satisfactorily maintained, and all requirements were met by the consignments received from the factories, and values continue steady. The sale for hams has improved as is usual for this time of the year, and much heavier bookings were made for Christmas delivery. Values are:—Best quality sides, 9½d to 9¾d. per lb.; middles, 9½d. to 10d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 1s. 2½d. to 1s. 3d ; cooked, 1s. 4½d. per lb.; lard, bulk, 5d. to 5½d.; prints, 6d. to 6½d. per lb.

ALMONDS.—After a period of short markets quantities increased, but sales kept the floors fairly cleared, and rates are:—Softshells and Brandis, 9d. to 10d ; hardshells, 5¼d. to 5½d.; kernels, 1s. 11d. to 1s. 11½d. per lb.

HONEY.—Unfortunately there is no improvement to report in the sale of honey, and very heavy stocks are still held. Present values are:—Prime quality clear extracted 2¼d. to 2¾d. per lb.; lower grades, 1d. to 2d per lb.

BEESWAX.—Was in fairly heavy supply, and turnover was steady at 1s. 3d. to 1s. 4d. per lb, according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms, which are in every way the best equipped in the State. The catalogues submitted during November were shorter than usual, the supplies of young cockerels, turkeys, and ducks being much less than was expected. There was a slight increase towards the latter end of the month, and no doubt will continue to improve throughout December, especially during the Christmas sales. Prices for prime quality stock are expected to rule high. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 4s. to 5s. 6d.; nice-conditioned cockerels, 3s. 3d. to 3s. 11d.; fair-conditioned cockerels, 2s. to 3s. 2d.; chickens, lower; heavyweight hens, 2s. 6d. to 3s.; medium hens, 1s. 4d. to 2s.; light hens, 1s. to 1s. 3d.; couple of pens of weedy sorts, lower; prime young muscovy drakes, 5s. 6d. to 6s. 6d.; young muscovy ducks, 3s. to 4s.; ordinary ducks, 1s. to 2s. 3d.; ducklings, lower. Geese, 3s. 4d. to 5s. 6d.; goslings, lower. Turkeys, good to prime condition, 10d. to 1s. 1d. per lb. live weight; turkeys, fair condition, 7d. to 9d. per lb. live weight; turkeys, poor and crooked breasted, lower. Pigeons, 5½d. to 6½d. each.

POTATOES.—New season's, 8s. per cwt.

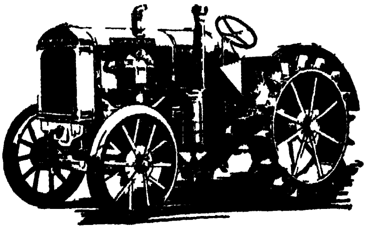
ONIONS.—New season's, 8s. per cwt.

MODERN as the day—
this reliable
FARM EQUIPMENT

Built on long and close experience of farming requirements, these practical lines give you the best that modern engineering skill can devise. Your local McCormick-Deering agent will be pleased to show you their qualities.

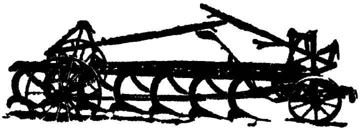
McCORMICK-DEERING W-30 TRIPLE-POWER TRACTOR

The new McCormick Deering W-30 triple-power tractor is strikingly individual in type and character With a turning radius of only 13½ feet, W-30 is distinguished by unusual power and stamina for a tractor of its compact dimensions. Built like a motor car, it has special gears and anti friction bearings on the steering shaft and steering knuckles making it one of the easiest of all tractors to steer



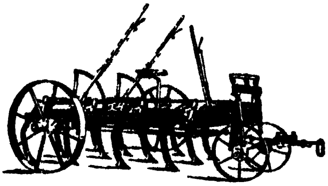
McCormick-Deering W-30 Tractor

McCORMICK-DEERING STUMP-JUMP MOULDBOARD PLOUGHS.



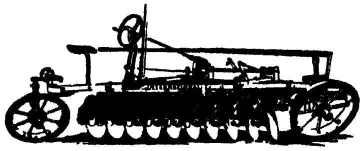
Made in 5 and 7 furrow sizes, these ploughs can be adjusted to cut 6, 7 and 8 inch furrows Yielding springs allow the jump beams to yield sideways when striking an obstruction For operation with tractor a special power-lift attachment can be supplied at extra cost

INTERNATIONAL STUMP-JUMP SCARIFIERS.



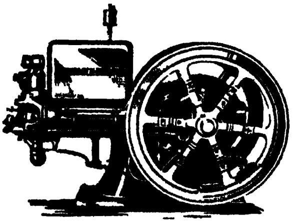
Made in 5, 7, 9 and 11-ft. sizes, the International stump-jump scarifier has many serviceable features. It has ample clearance, is easy to operate—direct and positive in action. A splendid implement for cultivating fallow land Can be equipped for use with horses or tractor

INTERNATIONAL DISC CULTIVATING PLOUGHS.

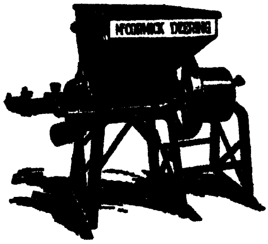


The International "single jump" disc cultivating plough is made in 6, 8, 10 and 12 furrow sizes, equipped with 22-inch discs spaced 9½ inches apart. Width of cut can be varied from 5½ to 7 inches. This plough can be equipped for operation with horses or tractor

McCORMICK-DEERING KEROSENE ENGINES.



Operating on kerosene fuel at low cost, the McCormick Deering engine is the ideal mechanical 'handy man" on the farm Built in 1½ 3 and 6 h.p sizes Stationary and portable types



McCormick-Deering Feed Grinder

McCORMICK-DEERING FEED GRINDERS.

McCormick-Deering feed grinders are made in 6 and 8-inch sizes with capacities to suit any farm; will grind maize on the cob and crush the cobs; will also grind small grain and shelled maize. The 6-inch feed grinder has a capacity of 9 to 48 bushels an hour, and the 8-inch machine a capacity of 18 to 72 bushels an hour.

* No report received during the month of November R In recess.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

WOMEN'S BRANCHES.

CORRECTION.

On page 567 of the November issue, the paper "Herbs, Spices and Condiments" is shown as having been prepared by Mrs. Edith Kidman; this should be Mrs. Thomas Kidman of Penola.

SUMMER DRINKS.

[Miss L. BLUMSON, Laura Bay.]

Summer home-made drinks are freely used in many homes during hot weather; especially do the farmers' wives take advantage of making the many different kinds of drinks which are simple and easy to make. *Boston Cream.*—3 pints boiling water, 1½ cups sugar, 2ozs. tartaric acid (powder), 1 teaspoon essence of lemon, white of 2 eggs. Pour boiling water over sugar, let it get cold, then add tartaric acid, whites of eggs beaten to a froth, and essence of lemon. Bottle and it is ready for use. Put 2 or 3 tablespoons in a tumbler of water. Add a pinch of carb. soda if liked. *Chilli Wine.*—2lbs. sugar, ½oz. tartaric acid, 1 quart boiling water, 25 to 50 chillies (according to size), 1 teaspoon essence of lemon. Boil chillies in water for 10 minutes, then strain on sugar and acid. Stir until sugar is dissolved, then lift off fire, and add essence of lemon; bottle. About 1 tablespoon to a glass of water. *Lemon Syrup.*—2lbs. white sugar, 3 pints boiling water, ½oz. tartaric acid, ¾ teaspoon essence of lemon, ½oz. cream of tartar. Pour boiling water on, and stir well. Let cool, and bottle. If wanted to keep long boil it 15 minutes. Two or 3 tablespoons to a glass of water. *Raspberry Vinegar.*—Boil 3 pints water, 3lbs. sugar. When cold add 1 cup vinegar, 2 teaspoons raspberry essence or more to taste. Colouring to taste. *Emperor's Orange Syrup.*—The peel of 8 oranges peeled very thinly, 5lbs. sugar, 1½oz. citric acid, 8 tumblers cold water. Put all together in an earthenware jar, and stir every hour with a wooden spoon; when the sugar is dissolved, strain and bottle. Use a small quantity with water added to taste. *Lime Juice.*—1½lbs. sugar, 1½ pints water, 3 teaspoons tartaric acid, ½ a small bottle of essence of lemon. Boil sugar and water, also acid, together for 1 hour; when cool add essence of lemon. *Good Fruit Salts.*—2ozs. each of tartaric acid, Epsom salts, cream of tartar, carb. soda, and 1oz. magnesia, ½lb. lemon-flavoured icing sugar. Mix thoroughly together. *Apple Beer.*—A splendid summer drink. 18 tart apples (large), 4galls. water, 5 cups sugar, 1 cup raisins, 2 cups hop yeast, 1 finely shredded lemon or 1 teaspoon essence. Boil water, sugar, and raisins, finely shredded apples, and lemon. (Do not peel or core apples.) Remove from fire at once, and stir occasionally until cool; then add yeast, stand 12 hours, then strain and bottle. Tie down corks, and put in a cool place. *Cold Water Ginger Beer.*—2lbs. sugar, 2galls. cold water, 2 tablespoons each cream of tartar and ginger, 1 teaspoon essence of lemon, 1 small cup of yeast. Stir all well together, and stand over night. Strain and bottle. Ready for use in two or three days. *Hop Beer.*—4galls. water, 1 handful hops, ½ cup horehound, 4lbs. sugar, 1 tablespoon each treacle and ginger, 1 handful bran. Boil until hops stop floating, stand to cool, then add 1 cupful of good yeast. Strain, let stand for about 12 hours, then bottle.

CHRISTMAS COOKING.

Miss R. Blumson, of the Laura Bay Branch, read the following paper:—

The cake should be made 2 or 3 months before Christmas. Special attention must be paid to the heat of the oven as the cake is more difficult to bake than to actually make. The oven must be hot when the cake is put in, and reduced after 15 minutes, and then cooked in a moderate to slow oven. The oven is responsible for the many failures beginners often experience. As making the Christmas cakes is a long job, have everything prepared the day before. Great care should be taken to read the recipes through thoroughly as one item left out may spoil the cake. Tins must be greased and covered with 3 or 4 thicknesses of paper. The papers around the sides of the tins must not be too high, or sufficient heat will not pass over the top of the cake, thus causing it to drop in the centre. Self raising flour should not be used, as it contains too much rising, and also makes the cake rise unevenly. Use plain flour and 1 teaspoon carb. soda to 1¼lbs. flour. The quantity of fruit and eggs makes the use of cream of tartar unnecessary. Always have the fire burning a few hours before the cake is put into the oven in order to have an even heat. Use a wooden spoon for mixing. Sometimes the cake mixture curdles when adding the eggs; to overcome this, beat quickly, and it will generally become smooth again; if it does not, add a spoonful of sifted flour. The fruit (which must be rolled in flour) should not be put in the cake damp or it will all sink to the bottom. Salt or bran sprinkled on the bottom will prevent it from burning. The cakes should bake from 2 to 5 hours according to size. They must then be wrapped in grease-proof paper and kept in an airtight tin. The almond icing (or paste) must be made quite stiff so that it can be rolled without sticking to the rolling pin or paste board. When rolled out thin, place over top of cake and trim off evenly. Then roll more out for the sides.

Recipe for the Almond Icing.—½lb. ground almonds (almond meal), 12ozs. icing sugar (or 6ozs. each of icing and castor sugar); mix with the white of an egg and lemon juice. A dessertspoon of brandy is sometimes used, but lemon juice gives the icing a nice flavour. Orange flower water can be added if liked (but can easily be omitted if not on hand). After trimming the almond icing off evenly, leave to dry before going on with royal icing. Recipe—8ozs. icing sugar, white of 1 egg, few drops of acetic acid or lemon juice, few drops blue colouring. Beat well until stiff enough to stand in points if lifted from the spoon. Use a flat knife dipped in hot water to smooth it with. Ice the cake 4 or 5 days before intended for use. A little glucose (or maize syrup) improves white icing and prevents it from becoming hard and brittle. Use glucose in the proportion of 1 dessertspoon to 1lb. icing sugar. There are numerous decorations on the market. Piping needs practice, but looks very effective. If an icing set is not available, cut a hole in the corner of a clean paper bag and use that as a forcing bag.

Christmas Pound Cake.—1¼lbs. plain flour, ½ grated nutmeg, ¼ teaspoon salt, 1 teaspoon cinnamon, 1½ teaspoons spice, 8 eggs, 1lb. butter, 1 lb. sugar, 1½lbs. sultanas, ¾lb. raisins, ¼lb. currants, ¼lb. dates, ¼lb. candied peel, 1 dessertspoon treacle, small teaspoon carb. soda stirred in a little boiling water, 2 tablespoons blanched almonds, a little rum or brandy if desired.

Christmas Cake.—1lb. each sugar, currants, raisins, butter, lemon peel, plain flour; 6 dried figs, 1 nutmeg, 9 eggs, ½lb. almonds cut finely, little essence lemon, a little mace, 1oz. preserved ginger.

Rich Christmas Cake.—1¼lbs. plain flour, 1lb. each butter, brown sugar, sultanas, raisins, currants, ½lb. each mixed peel, almonds (blanched), preserved ginger, figs, ¼lb. crystallised cherries, 8 eggs, 1 gill brandy, ½ grated nutmeg, 1 teaspoon mixed spice, 1 teaspoon cinnamon, 1 teaspoon carb. soda, ½ teaspoon salt, a little caramel.

Method for Above Cakes.—Cream butter and sugar, add eggs 1 at a time and beat well, add flour and fruit alternately, mixing all thoroughly. Spices, &c., should be sifted in with the flour, and lastly, soda added in a little boiling water.

Puddings.—These may be either steamed in a basin or boiled in a cloth, with the former, the pudding is much lighter and also a better shape. The water must be kept boiling and more water added when necessary while cooking the pudding.

Christmas Pudding.—1½lbs. bread crumbs, ½lb. flour, 1lb. finely shredded suet or butter, ½lb. sugar, 1lb. currants, ½lb. raisins, ½lb. candied peel, 1 nutmeg, 1 packet mixed spice, ¼lb. chopped almonds, 8 eggs. If suet is used, all the dry ingredients should be mixed together and the eggs (well beaten) added last. If using butter, cream the butter and sugar as for a cake, then add beaten eggs and dry ingredients by degrees. Cook in a cloth or basin. Cook from 4 to 6 hours.

Christmas Plum Pudding.—½lb. butter, ¾lb. raisins, 4ozs. mixed peel, 1lb. dark sugar, 1lb. sultanas, 7ozs. breadcrumbs, 5ozs. flour, 2½ozs. almonds (chopped finely), ½ nutmeg (grated), 1 teaspoon each ginger, cinnamon, and allspice, 1 teaspoon salt, 1 teaspoon baking powder, 4 eggs, ½ cup milk. Beat butter and sugar to a cream, add eggs one at a time, and dry ingredients. Steam for 7 hours, or if put in 2 basins, 4 hours each.

Hard Times Christmas Pudding.—1 cup flour, ¼ cup treacle, 2ozs. each suet (or bare tablespoon butter), currants, sultanas, 2 or 3 tablespoons milk, ½ teaspoon carb. soda. Rub suet (or butter) into dry ingredients. Warm treacle and add milk, then mix all together. Pour into well greased basin and steam for 2½ hours.

Good Christmas Pudding.—1lb. each currants, raisins, butter, breadcrumbs, 8 eggs, 1 handful flour (plain), 2 tablespoons brown sugar, 1 dessertspoon treacle, 1doz. minced almonds, ½lb. lemon peel, 25 prunes (cut up), ½ teaspoon carb. soda, 1 wineglass rum or brandy. Mix all dry ingredients. Beat butter to a cream then beat yolks in 1 at a time. Beat white stiff and add to butter and yolks, then mix into dry ingredients, stir well and lastly add brandy. Add soda last in a little milk. Soda darkens and also makes the pudding much lighter.

Plain Christmas Pudding.—1 cup each suet, breadcrumbs, flour, raisins, currants, sugar, milk, 1 teaspoon carb. soda, little lemon peel. Mix suet into flour, add sugar, fruit, and breadcrumbs, and mix with milk. Boil for 2½ to 3 hours in a cloth. The above puddings can be served with whatever sauce desired. Although brandy sauce is considered the correct sauce for Christmas puddings, cornflour, arrowroot, or custard sauce is quite nice.

Brandy Sauce.—¾ pint water, 2 tablespoons sugar, ¼ pint brandy, 1½ dessertspoons arrowroot (blended in a little water), little brown colouring if liked. Boil water, add sugar and arrowroot. Stir until it thickens. Remove from the fire and add brandy. Do not make until the last minute (nor let it boil after brandy is added) as reheating causes brandy to lose its flavour.

English Christmas Mincemeat.—1½lbs, raisins, 1lb. currants, 1lb. sultanas, ½lb. lemon peel, 1½lbs. apples (after being cored and peeled), ½ packet mixed spice, 1 teaspoon salt, 1 grated nutmeg, ¾lbs. suet (or 10ozs. butter, melted), 1 lb. sugar, ¼ pint brandy. Chop all above ingredients separately and mix well together. Mix in a large basin, add ½ pint cooking brandy. Paste down in jars. Make it 2 or 3 months before use if possible.

[By Mrs. A. Andrews, Snowtown.]

Much forethought and preparation are involved in making the arrangements for the smooth running of Christmas menus. With possible heatwaves and a last minute rush to finish the reaping, &c., one is left with little time to spare immediately before Christmas Day, so that it is well to take advantage of any cool days to get the cakes and puddings made.

In suggesting a Christmas menu, and in dealing with the necessary preparation, it is proposed to deal only with plain, ordinary fare, and although some may wish to make more elaborate preparations, this list does not involve more labour than the one woman-power household can manage.

The suggested menu is as follows:—

Dinner, Hot.—
    Roast poultry (turkey, goose, duck, or fowl, as preferred, with seasoning).
    Baked ham.
    Vegetables—Greens, French beans, or green peas; new potatoes.
    Giblet gravy.
    Pudding—Plum, with sauce.
Tea.—
    Cold meat.
    Salads, pickles, &c.
    Custard, jelly, stewed fruit, or trifle.
    Christmas cake.
    Various other cakes, biscuits, &c., as preferred.

In addition to this list, have a supply of tinned meats and preserved fruits on hand in case the weather is hot or for the hastily arranged picnic.

Christmas Cake,—This may be made a month to three weeks before Christmas and stored in an airtight tin until the day before, when it should be iced. Prepare the fruit the day before the cake is to be mixed. Having this weighed and prepared, making and baking the cake is quite a simple task. *Recipe*:—Beat 1lb. butter to a cream with 1lb. sugar, add 10 eggs 1 at a time, 3 dessertspoons treacle, 1 teaspoon carb. soda, 4 to 4½ cups flour. Add fruit floured with half the flour, 1lb. each sultanas, currants, raisins, dates, ¼lb. almonds (blanched and chopped), ½lb. lemon peel. To other half of flour add 1 nutmeg (grated), ½ teaspoon ground cloves, 1 teaspoon cinnamon. Enough for 2 large cakes. Bake in moderate oven for 3 hours.

The Pudding.—The pudding may also be made weeks beforehand and boiled again on Christmas Day. *Recipe*:—1lb. currants, 1lb. raisins, ¼lb. lemon peel, ¼lb. almonds (blanched and cut up), ½ packet mixed spice, 1 teaspoon ground ginger, 1lb. each sugar, suet, plain flour, ¼lb. breadcrumbs, ½ teaspoon carb. soda in one tablespoon hot water, 8 eggs, 1 tablespoon brandy. Make into 4 puddings and boil for 6 hours. Hang in a dry place until required. Boil for 2 hours on Christmas Day. *Sauce*—Boil 1qt. milk, sweetened to taste; thicken with cornflour; serve cold.

Poultry.—This should be in hand a day or two before Christmas Day, and the bird selected—preferably a young male of plump appearance—should be plucked and drawn the day before and hung in a cool place. The bird should be stuffed, spread with dripping, and placed in a hot oven, frequently basted, and baked for 2 to 3 hours, according to size. The giblets may be boiled and the stock used for making the gravy. The seasoning may be placed in the bird or steamed separately in a basin. Some prefer to do it the latter way in hot weather if the bird to be cooked will not all be eaten on Christmas Day. *Recipe:*—2 cups breadcrumbs, 1 onion (grated), 1 tablespoon dripping, thyme, pepper, and salt to taste. Bind with beaten egg. Use sage for duck or goose.

The Ham.—The Christmas ham is a great standby in hot weather. A little served with the poultry for Christmas dinner adds to the attractiveness of that meal, or if, as is preferred by some, the Christmas dinner is a cold one, the ham plays an important part in the menu.

The ham should be soaked for several hours before it is cooked. Trim off all unsightly parts. Put it in a preserving pan with a lid in lukewarm water and bring to boil. Allow to simmer gently until done. Leave in water until cool. Remove the rind, place in meat dish, sprinkle with breadcrumbs, nutmeg, and cinnamon, and stick cloves in the fat. Pour over a pint of the liquid in which it was boiled and bake for ¾ hour in hot oven, or until nicely browned. This baking greatly improves the flavour of the ham. Time to boil ham—about 2 hours.

Salads.—Salads to serve with cold meat must be absolutely fresh to be appetising, although the following may be prepared the previous day.

Beetroot in Jelly.—Boil some tender beets, cut in slices when cold. Dissolve 1 tablespoon of powdered gelatine in ½ cup of vinegar. Add enough warm water to make a pint of liquid. Pour this, seasoned to taste, over beetroot and put in a cool place to set.

Mayonnaise for Lettuce Salad.—Mash the yolk of a hard-boiled egg with 2 tablespoons sugar, 1 teaspoon of mustard, ½ teaspoon salt, ¼ teaspoon pepper. Moisten with vinegar and work into smooth paste. Add a small cup cream and blend well. Garnish top of salad with sliced egg-white. Pour mayonnaise over the top.

Homestead Meeting, Snowtown Women's Agricultural Bureau.

FANCY WORK.

[Paper read by Miss T. Barnett (Laura Bay Branch), at Conference at Ceduna, on 4th July, 1935.]

"Fancy work is an art as well as a very pleasing pastime, especially for long winter evenings. Before commencing a piece of work it is well to consider the purpose and use to which the finished article is to be put. Quite a lot of good work is spoilt and time wasted by working unsuitable materials and inappropriate designs. If the article to be worked is to be in constant use and likely to receive hard wear, the foundation material chosen should be of firm durable texture and the working thread a good quality silk; and if it is to be frequently laundered, fast colours should be specially selected. Conventional designs are more easily treated than natural ones, as they can be worked in any colouring to match the general scheme of the room of which the article is to form a part. If floral designs are preferred, be sure to work them near as possible to the natural colouring, otherwise the appearance of the article is spoilt. In working the poppy and flowers with similar petals, remember to keep a wavy outline, as every change in the direction of stitches means variety of tone, if not a tint. The direction of stitches for the flowers is towards centre, but should follow almost invisibly the outline of the flower. When the petals are deeply cupped, which is frequently the case, the direction of the stitches is not entirely towards the centre, but is given by a series of long and short stitches, so placed as to overlay one another at the base. For conventional designs, plain satin stitches, straight and slanting, may be used with good effect. When working stems or any curved lines the stitches must be much closer on the inner side of the curve than the outer. Care must be taken that the darkest shades are placed where designs are heaviest, otherwise the design is likely to appear top heavy. This rule is most essential when working sprays of flowers, as full-bloom flowers are always higher in tone than the buds. Fineness is a very strong point in fancy work, and must be done as neatly on the back as on the front. Knots must not be used; when finishing off run the thread along underneath the stitches at the back of the work.''

QUESTION BOX.

At the meeting of Belalie Branch on 13th August, 1935, a paper ''Citrus Fruits and Their Uses,'' was read by Mrs. Dave Brooks. Miss Houghton gave an illustrated address dealing with New Zealand. Answers to the Question Box were as follows:—*For Frost-bitten Knees.*—Use olive oil rubbed in; wear old stockings; rub in good skin cream. *Trees and Shrubs that will do well on Bore Water.*—Acacia, Aloysia, Scarlet Veronica, Diosma, Eucalyptus, Fabianna, Genista (Brooms), Laurustinus, Oleander, *Schinus molle* (Pepper Tree), *Salix* (Willow), Tamarix, Tecoma, Tagasaste (Tree Lucerne), Veronica. *How Moist should a Rich Fruit Cake be before Baking.*—So that the mixing spoon will stand up in it. *To Dry Woollens.*—Spread on a flat surface in the shade in open air. Pad sleeves and bodice with tissue paper. When nearly dry turn to other side. *How to Remove White Golf Ball Paint from Fingers.*—Use ''Solvol,'' eucalyptus, or kerosene. *Cold Cream.*—Melt white beeswax with liquid paraffin. Dissolve borax in warm water, and while warm mix with melted wax. Set aside 24 hours. Add perfume and mix. *Food Value of Wholemeal.*—Varies in different varieties of wheat. Nabawa contains 7.1 per cent. to 8.6 per cent. gluten, 7.4 per cent. to 8.8 per cent. protein. The lowest in these yielded 73.2 per cent. flour, and the highest 71.8 per cent. flour. This is probably due to the soil and to climatic conditions under which the wheat was grown. *Most Hygienic Filling for Pillows.*—Feathers, because they can be washed. *Best Feed for Young Turkeys.*—Hard-boiled eggs chopped with lettuce, onions (green), spinach, stinging nettles, or any greens. *To Keep Paint Brushes Soft.*—After using wash in warm soapy water and dry in open air. (Secretary, Mrs. E. L. Orchard.)

A FEW KITCHEN HINTS.

[Supplied by Mrs. A. J. Bowell, Laura Bay.]

1. It is a good plan when baking fruit cakes to put an asbestos mat under each cake to keep them from getting burnt underneath.

2. Rub off grease spots on your stove and kettles with newspaper.

3. Keep a lemon in your kitchen. It will be very handy for taking stains from the fingers after peeling fruit and vegetables.

4. Keep an old catalogue on your kitchen table for standing hot pots of any sort. It saves the oilcloth; just tear off the dirty page and burn it and you still have a clean book and table.

5. For brown marks on teacups, rub on a little Dutch cleanser, or some ashes and marks will come off quite easily.

6. When you are about to clean your stove with blacklead, first dust your hands with flour, rubbing it well into the knuckles and fingers, then get a paper bag, and put your hand into it to hold the blacklead brush handle. Use a bag for each brush and you will find that your hands will be quite easy to clean afterwards.

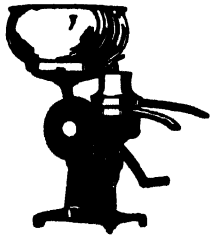
7. You can keep your teatowels and dishcloths a good colour if you keep your aluminium saucepans off the open fire. Put them on the stove in plenty of time to get

hot, otherwise put in boiling water from the kettle if you want it to boil quickly. If you put them on the open fire grease the bottom of the saucepan first, then, before you wash it, rub off the black with some newspaper. (Secretary, Miss T. E. Barnett.)

PICKLES, SOUR AND SWEET.

The following paper was read by Mrs. W. W. Bowell at a meeting of Laura Bay Branch on 13th August:—"There is a great variety of pickles, each country have their own particular fancy. Australians, Indians, and Americans use pickles, sauces, and chutneys more than most other countries. The hot climates seem to give people a taste for them, because cold meats are used more, and need something tasty to help people's appetites in hot weather. The Indian mango pickles and chutney are very nice and appetising; some are mild, but most are very hot. Pickles are made from almost all kinds of vegetables and fruit. Tomatoes are one of the most useful fruits, and mixed with melon and onions, or marrows, or any other vegetable, either in clear vinegar or a mustard mixture and with various spices and flavourings, make many kinds of pickles. Melon and marrows are useful to give body to pickles, and these vegetables absorb other flavours, making a little go a long way when certain kinds are scarce. Figs make the best pickles. Grapes, pears, quinces, plums, peaches, apples, mangoes, cucumber, and cauliflower all mix well with melon and onions. Red cabbage and walnuts are also good. Chutneys are more of a mixture of fruits than pickles, with the addition of raisins, red and green peppers, rhubarb, currants and sultanas, ginger and garlic. Chutney is usually rather sweet and hot, and can be varied according to taste. One recipe is:—Take a bottle of piccalilli and mince, add a tin of plum jam and boil. There you have an easily made chutney. There are so many ways of making pickles that it is hard to choose recipes. *Fig Pickle.*—Cover as many half-ripe figs as you want with vinegar and soak three days. Then pour off and boil vinegar with 1lb. sugar to a quart of vinegar, and 2ozs. salt, 1oz. of allspice, 1oz. cloves, 1oz. whole ginger, and a few peppercorns. Boil 10 minutes, then pour over the figs while hot and cover when cold. Ready in three weeks. *Mustard Pickles.*—Cut up 3lbs. of tomatoes and 3lbs. onions. Cover with a brine over night. Put on and just bring to the boil and strain. Mix 1½ to 2 cups sugar, ½cup flour, 6 tablespoons mustard, 1 tablespoon turmeric, 1 teaspoon pepper and salt to taste with some of the 2 qts. of vinegar. Put the remainder of vinegar on to boil, stir in the above mixture and just bring to boil again. Any other mixture of vegetables can be used.

There is only One Best
SEPARATOR
THE
"ALFA LAVAL"



Holds the
World's
Record
for Clean
Skimming

Rustless Metal Bowl and Discs.

DRESSMAKING.

[Paper read by Miss M. MILLER at a meeting of the Balhannah Branch on 17th July.]

The subject of clothing claims the attention and interest of all women—some more than others. Let us divide these women into three groups.

Group I.—The women who have a natural gift for designing and constructing clothing artistically; also women who have acquired this ability would come under this heading. If these women are given material, scissors, tape measure, pins, etc., they, through natural ability, or carefully though-out design, will turn out a first class garment.

Group II.—Women who cannot design yet have ability to construct.

Group III.—Consists of those who know little or nothing of designing or construction. These last two groups form the vast majority, and are wonderfully catered for by the pattern of to-day.

It is most important that the home dressmaker should know how to take measurements thoroughly, and accurately. Not knowing the correct way often results in the waste of good material, therefore, every care should be taken.

Tie a tape rather tightly round the natural waist line—this is a guide for other measurements taken to and from the waist.

1. **Neck:** this measurement is taken firmly.
2. **Bust:** measure loosely—a good idea is to pin the tape measure well up on the shoulder blades, then bring loosely round the fullest part of bust.
3. **Across** the chest, between the armhole—about four inches below the throat.
4. **Length** of front: taken from the two little bones at base of throat to the waist.
5. **Length** of shoulder.
6. **From** front waist to shoulder and then over to back waist.
7. **Under** the arm: from well up in the armpit to the waist.
8. **Back:** taken from nape of the neck to waist line.
9. **Width** across the shoulder blades is taken at the widest part of the back.

Sleeve—

10. Armhole: This is taken with arm hanging loosely at side, round top of armhole over the point of the shoulder blade.
11. Front seam of sleeve—taken from the front of arm pit to wrist with arm straight.
12. Outside measurement of sleeve—measure from top of arm hole to elbow (arm bent) to wrist.
13. Around upper arm—an easy measure.
14. Round elbow—firmly—arm bent taken over point of elbow.
15. Wrist—firm.

Skirt—

16. Waist—taken firmly round waist line.
17. Hip measurement is taken loosely about 6in. below waist line—also a good idea to sit on tape and take that measurement.
18. Front length—taken from waist to floor.
19. Side length—waist to floor.
20. Back length—waist to floor.

For the required length of skirt, deduct the number of inches to desired length from floor. Other measurements may be taken, such as from shoulder to required length, etc.

Drafting—There are different methods. If one can have a term or so learning drafting, designing, and pattern cutting, dressmaking is simplified—if unable to do so, any good dressmaking teacher will cut out and fit you with a foundation calico pattern from which any frock can be designed, and, of course, bought paper patterns may be placed on this foundation pattern, and cut to your measurement.

There are many reliable paper patterns to be bought—Weldons, McCall, Butterick, and others. Often these patterns need very little alterations; they may be tested by your measuremens, but the safest way for an inexperienced worker to follow is to pin the parts of the pattern together, slip it on, and note what corrections seem necessary—some workers get good results by simply holding pieces up against the figure, but this is not as safe a way as trying the pattern on, which, if carefully done, will not tear the pattern.

When altering patterns one should remember that the outline, as carried out by the designer, should not be altered in any way—work from the inside.

When pattern has been altered to fit the individual measurements the material is prepared for cutting out. Examine pattern or design of cloth. Floral designs may run in one direction. Plaids may have an up and down—stripes may have a right and left, because of the arrangement of stripe and so have to be cut one way. Always be most careful when placing patterns on velvet to have them all the same way, and to have the pile running from the bottom upwards.

Careful cutting out makes so much difference to the look of a finished garment, that this first process should never be hurried.

Arrange all the pieces of pattern on material before cutting—avoid raising when cutting out by lightly resting left hand on material.

A little extra time and patience spent in pattern marking will save a great deal of time when fitting later on. A tracing wheel may be used on thin materials though tailors tacking is better (for this use tacking cotton). Tailor's chalk may be used on some of the thicker materials. It is wise to mark all lines of pattern. Pin seams together and tack before machining.

Seams.—The most popular and simplest seam is a single or flat seam made by joining two pieces of material together, right sides facing. This seam sets well. Except when seam comes under lining it should be neatened off. By neatening off, I mean, notching, overcasting, or turning in and machining and then pressing flat. For curved seams notching is essential. This flat seam is always used on tailored clothes.

After the flat seam, the seam most used is French seam, *i.e.*, a seam within a seam. This is a neat way of stitching silks and should be narrow in width—about ¼in.—allow for proper setting.

The fitting of a frock is very important. Sleeves often worry—never cut two sleeves for one armhole. If the sleeve hangs in wrinkles in the front, the back of the sleeve has been set too far to the front and needs resetting more toward the back and if the wrinkles are in the back, *vice versa.* The grain of the material should run straight from top of sleeve to elbow.

A good idea when fitting and turning up the hem is to cut a strip of cardboard and notch one side the number of inches from one end that the skirt is to be from the ground (stand on table). Get your helper to move notched cardboard round bottom of skirt putting in pins parallel with notch—then the hem can be turned at pin line.

False hem can be cut either to shape of skirt or with crossway strips. Invisible hemming is used on tailored skirts and dresses; take up just one or two threads, then insert needle into turned hem, pass along about ¼in. before bringing out in the usual way.

AND BLUE STAR LINE.

Main Office in South Australia: 18, KING WILLIAM STREET, ADELAIDE.
Head Office: MELBOURNE.

The tailored hem is made with binding machined on to edge of hem and then invisibly stitched.

Shoulder picks or pleats should not run with thread of material but with sleeve line.

Bias loops are used for an even closing, mostly for neck and sleeve openings. Make a bias fold and press flat. Tack in loops to fit buttons on turned edge, stitch down, and bring fold over the rough edges. Hem flatly and press.

Hemstitching and faggotting lend a very effective finish and decoration to a frock.

To allow fullness in front for tucks split pattern and spread apart.

For flares it is necessary to cut a foundation paper pattern and cut up from the bottom 2in. or 3in. apart, and spread out on material. (Secretary, Miss D. Spoehr.)

INEXPENSIVE CHRISTMAS GIFTS.

The following paper was read by Miss H. Telfer at the November meeting of the Warcowie Branch:—

A Christmas gift can be enhanced with very little trouble and expense and made a delight to the eye. In the first place a gift sent in a box is far more attractive than an untidy parcel. Coloured tissue paper costs little and gives a very festive look to parcels. White string can be dyed various colours or dipped in red ink, and is more attractive than ordinary coloured string. Narrow ribbons are also inexpensive. A box of hankies tied with lavender ribbon with a sprig of dried lavender in the ribbon will have an added charm. A wrap of white tissue paper can be used with scarlet ribbon for the tying and add a sprig of holly at the bow. Another wrap can be made by tying the article first wrapped in pale-blue tissue and with rose-coloured ribbon and a rose cut from wall paper or from a seed catalogue and pasted on the lid of the box. Round boxes such as those used for face powder are very dainty done up in a large circle of tissue paper which is gathered up to the top and tied, and the edges fringed. It has the appearance of a large chrysanthemum, and the paper may be cut in points. Coloured pictures cut from magazines, &c., and pasted on the outside of parcels also add to their appearance. A charming exterior makes a pleasant impression on the recipient of the gift.

SUITABLE GIFTS.

Evening Dress Hanger.—No modern wardrobe is tall enough to hang long evening frocks in. All that is needed are two cheap wooden coat hangers, about 2½yds. of narrow ribbon, and some scraps of silk of coloured dress material. Take the hanger part off one coat hanger and pad both hangers first with some wadding or rag, then cover with material or silk. Take the one with the hanger part still attached and fix a piece of ribbon about 15in. long to each end of it, about 2in. from the end. The second hanger has a piece of ribbon 2ft. long attached in the same position as the first. Make a loop at the other end of both hangers. This loop is then slipped over the end of the first hanger, and the ribbons on the first hanger tied in a pretty bow to keep them in place. To hang a dress on it, remove the bottom hanger, hang the dress upon the top by the shoulders, fix the bottom hanger on again, and lift the skirt part and hang carefully over the suspended hanger. A few artificial flowers added to the centre of the upper hanger gives a finishing touch to this article.

Shoe Cleaning Pads.—Even though shoes are cleaned just before leaving home, by the time a short distance has been walked outside, the shoes are covered in dust. A pad that can be kept in the handbag is a novel idea, and is very easily made. A piece of oilcloth, poplin, or canvas, or any firm material about 4in. by 6in. is required. Line it with a soft material and then cut up a piece of velvet three-quarters of the length of the oilcloth. Turn in one end, place the oilcloth and the first piece of lining on the wrong side of the oilcloth and the second piece on top of that. Sew all raw edges together and bind all around. Roll into a little bundle or fold like an envelope. Shape and fasten with a press stud.

Traveller's Coat Hanger.—These are very useful when going on a holiday and take up very little space. All that is necessary is a piece of ribbon about 20in. long and two small pieces of elastic for the circles about 3in. long. Sew elastic into the circles and cover with ribbon, then allow 11in. for the loop in the centre to hang it up by. A newspaper rolled up tightly and put in these circles and bent the shape of the shoulders completes the hanger.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Angaston, Saturday, February 29th, 1936.
Mundalla, Wednesday, March 4th, 1936.
Mount Pleasant, Thursday, March 19th, 1936.

Agricultural Bureau Conferences, 1936.

River Murray (Swamps), at Wood's Point, Thursday, 20th February (Mr. F. P. Baily, The Point, Secretary).

Lower North, at Owen, Thursday, 27th February (Mr. A. Helps, Owen, Secretary).

Yorke Peninsula, at Arthurton, Wednesday, 4th March (Mr. T. H. Howlett, Box 8, Moonta, Secretary).

Mid North, at Beetaloo Valley, Thursday, 12th March (Mr. B. W. Giddings, Beetaloo Valley, Secretary).

South East (Lower), at Kybybolite, Wednesday, 8th April (Mr. A. S. Shepherd, Kybybolite, Secretary).

Dairying, at Strathalbyn, Thursday, 21st April (Mr. Reg. Sissons, Strathalbyn, Secretary).

River Murray, at Block E, Thursday, 18th June (Mr. J. C. K. Brigham, Box 65, Renmark, Secretary).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Rebate in Rail Carriage of Sheep.

In order to encourage the movement of sheep from the Northern areas to the South-Eastern portion of the State, the Railways Commissioner has approved of the payment of a substantial rebate on rail carriage of sheep from and to the area mentioned. The rebate which will be granted is 40 per cent. (40 per cent.) of the full van rates, made up of—

25 per cent. rebate for store stock.
15 per cent. rebate in return for the dispatch of wool from the South-East to Port Adelaide by rail transport during the next shearing after movement of sheep.

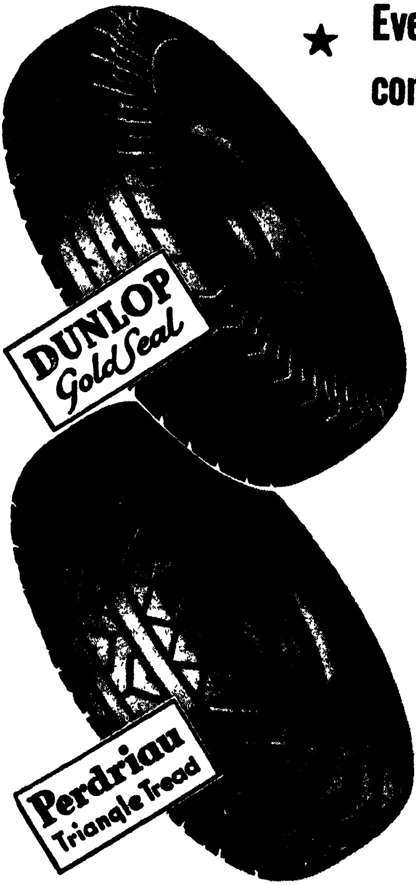
The rebate will be paid on sheep forwarded to *bona fide* graziers at Bordertown, or any station in South Australia situated South, or South-East thereof *from* any railway station within the following area:—

All stations from Burra to Quorn, inclusive.
All stations from Crystal Brook to Cockburn, inclusive.
All stations from Gladstone to Wilmington, inclusive.
All stations from Mount Mary to Morgan, inclusive.
All stations from Renmark to Barmera, inclusive.
All stations from Lameroo to Pinnaroo, inclusive.

This rebate will apply to consignments of *not less than* ten (10) four-wheeled vans of sheep consigned from the areas named above.

IT IS A SIGNIFICANT FACT....
THAT EVERY IMPORTANT
WORLD'S RECORD HAS
BEEN MADE AND IS HELD
by **DUNLOP**

★ **Every possible improvement in tyre construction is embodied in ...**



The New
WEFTLESS
CORD TYRES
by
DUNLOP

The First, Fastest and Safest Tyre in the World.

PRODUCTS OF DUNLOP PERDRIAU RUBBER CO. LTD.,

To obtain the benefit of the reduced rate the owner of the sheep must declare at the time the vans are ordered that it is his intention to return the wool to Port Adelaide by rail on a basis of thirty (30) bales per one thousand (1,000) sheep following next shearing. The 25 per cent. rebate account store stock will be paid immediately same is due, and the balance, 15 per cent., will be paid when the whole of the conditions have been complied with.

Crops for a Ti-tree Swamp.

After examining the soil taken from a swamp in the Edillilie district on which grows Cutting Grass, Black Broom, &c., Mr. W. J. Spafford (Deputy Director of Agriculture) has advised a correspondent who asked what would be the best crops to grow on this type of soil that he would be likely to experience some trouble in getting good pastures established on and near the swamp, and before much expense is incurred a few trial plots should be put down.

Plough the land deeply in early winter and work it thoroughly to mix the concentrated salts now at the surface into a greater body of soil. On one plot sow King Island Melilot at the rate of 6lbs. per acre, with superphosphate at the rate of 2cwts. per acre. On another plot sow Wimmera Rye Grass at the rate of 8lbs. per acre, with superphosphate at the rate of 2cwts. per acre. On another plot plant roots of the Giant Reed (commonly known as Bamboo and grown in most people's gardens as such). The Giant Reed shoots, up to 6ft. in height, are equal to green barley in feeding value, and are relished by all farm livestock. This plant will grow in very salty locations and is not used as often as it should be as a fodder plant.

If the land is as salty as the sample indicated, there is nothing really useful other than the three plants suggested (unless it be Saltbush), which is worth trying, but if it is not so very saline then Barley is the cereal to try. To try Barley, plough deeply, work the land thoroughly during the winter, and then at the end of July, or even in the beginning of August, sow Barley at the rate of 50lbs. seed and 1cwt. superphosphate per acre.

On the better land of the Edillilie district Dwalganup Subterranean Clover should do quite well, provided that it receives about 1½cwts. of superphosphate per acre per year. To establish this clover in a crop, use about 4lbs. of seed per acre, and on no account fire-rake the stubble, and be careful not to overgraze the clover after the crop is harvested. If it is essential to fire-rake the stubble to kill shoots, the land is not ready to put into pasture.

Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of the following publications:—

"The Rabbit in Australia," by David G. Stead.

VETERINARY INQUIRIES.

[Replies supplied by veterinary officers of the Stock and Brands Department.]

Via *Ballarat, Victoria, asks for drench for worms in sheep.*

Reply—The following mixture is recommended:—Copper sulphate, 1lb.; black leaf 40, 14 fluid ozs.; water, 6galls. To prepare—make the solution of copper sulphate first, then mix into it the requisite amount of black leaf 40. Doses—Adult sheep, 2 fluid ozs.; two-tooths, 1½ fluid ozs., &c. This combined drench is giving excellent results, and appears to be more effective than the drench of copper sulphate by itself.

"Kimba" reports draught mare with swelling on inside of leg near the tendon. Horse has been lame for six months.

Reply—Owing to the length of time that the animal has been affected without receiving appropriate treatment, it is very doubtful if she will ever become sound enough again to perform work though, of course, she may have a value for breeding purposes.

LISTEN! I'LL TELL YOU WHAT I'M DOING FOR FARMERS!

"I'm a Goodyear Farm Implement Tyre. This is the good work I'm doing on many farms throughout Australia:—

(1) "I'd give a tractor greater speed—allow high gear work on many jobs. I enable a tractor to do more kinds of work.

(2) "I cushion the tractor against jolts and jars — enabling it to live and work longer. Comfortable riding for the driver.

(3) "I can take a tractor straight from the paddock and on to the road for hauling. No waiting for wheel changes.

(4) "Any ground is the same to me. Hard or squashy, pebbly or sandy. My big tough diamonds grip equally well going forward, backward, or on hillsides.

(5) "By all this I save fuel, oil, labor and time for the farmer"

For complete details concerning Goodyear Farm Implement Tyres, write to The Goodyear Tyre & Rubber Co. Ltd., Branches in all capital cities.

GOODYEAR

FARM IMPLEMENT TYRES

MADE IN AUSTRALIA

The only treatment that could be tried would be to clip the hair short over the swelling. Then after bathing the skin with warm water containing a little vinegar, rub in all over the swelling for 15-20 minutes some red iodide of mercury blister (strength, 1 to 8—any chemist will supply this on request). The application of the blister is best done in the morning, and the animal should then be kept tied up short during the rest of the day so that she cannot bite the blistered part. The following morning wash off any remains of the blister with warm water and soap, snip with a sharp pair of clean scissors any unbroken blisters, and then anoint the blistered skin with sweet oil or lanoline, and turn the animal out for a lengthy spell. The application of the blister can be repeated in four or five weeks' time if necessary.

"Cherry Gardens" reports (1) *horse rubbing itself, and* (2) *heifer with blood in the milk of one quarter.*

Replies—(1) The cause is due to external irritation, such as presence of lice or small skin parasites, or accumulation of dirt on the skin, or might be due to the diet. Treatment: One warm day wash the animal thoroughly with soap and warm water, leaving the lather on for five minutes; then wash off thoroughly with rain water, and dry the animal by rugging or walking about. Then apply the following oily dressing:—Raw linseed oil, 1 pint; oil of creosote, 1 fluid oz.; flowers of sulphur, 4ozs. Shake well, and apply to affected parts with a body brush, and repeat at 3-4 day intervals. (2) This is not uncommon with heifers, and is due to engorgement of udder with blood, and the rupture of small blood vessels. It should clear up in from 4 to 14 days. Care should be taken when milking to handle gently.

Agricultural Bureau, Rendelsham, reports (1) *pony lame on the near hind leg for the last three weeks, and* (2) *aged draught horse stamping the ground with its hind feet.*

Reply—The animal should be exercised to see if the lameness is present at the walk or trot, also note if the pony will take full weight on the affected leg, and then carefully examine and see if any swelling is present about the stifle, hip, &c., and handle the tendon sheath and joints to discover if any heat or pain is present. An essential procedure is to examine carefully the foot by using a pair of wide-mouthed pincers and testing the foot for symptoms of tenderness when pressure is applied. The pincers should be placed at the junction of the wall and sole on the outer heel and gradually worked round to the inner heel. If any flinching is noticed, clean up the sole with a rasp, and look for evidence of a crack with an oozing of greyish or black matter, which indicates pus in the foot. If this is found it must be opened up and the foot placed in a hot antiseptic solution for 5-10 minutes and then into a hot bran poultice, repeating the operation for two to three days. When examining the foot the sole should be searched for foreign bodies, such as nails, wire, &c. If strain of tendons or a rick of one of the fetlock joints is suspected, the part should be covered with cotton wool and a fairly tight bandage, taking care to fill in the hollows on each side of the tendon sheaths in order that equal pressure is exerted. Remove and replace the bandage daily. (2) Stamping of the feet is usually indicative of irritation and is often associated with the presence of a small parasite on the skin of the legs. The following dressing should be applied with a body brush every three days, rubbing the mixture in well three or four times:—Lysol, 1 fluid oz.; raw linseed oil, 1 pint. Shake well before application.

"Cungena" reports a bull which, in fighting, broke off one of his horns, leaving a cavity into the head.

Reply—Provided there are no loose pieces of bone surrounding the cavity, the hole will close up completely if kept clean. Make two pads which would fit over the hole and keep it clean; one of them to be used one day and replaced by the second one. The pads should be soaked in the medicated oil and kept in place by tapes.

Ethyl has it!

IN SUPER PLUME ETHYL THERE ARE 5 POINTS OF POWER* THAT MEAN SUPER PERFORMANCE.

*3 POWER to sustain your *Highest Speed* . . . with a COOLER engine

Super Plume, by itself a SUPER spirit, has in addition, the anti-knock advantages of ETHYL—suppressor of all harmful knocks. Thus, not only is it the most POWERFUL, but the COOLEST petrol for summer use. Plugs are safer, Valves are COOLER ! Use Super Plume Ethyl with its 5 types of Power and get ALL the Speed and Pleasure your car can give you—with Maximum Economy !

HORTICULTURAL INQUIRIES.

[Replies supplied by A. G. STRICKLAND, M.Sc., Chief Horticultural Instructor.]

Is Cultivating During the Flowering Period Injurious to the Setting of Grapes?

This question was asked by the Koonunga Branch of the Agricultural Bureau.

Reply—There is no definite evidence that cultivation during setting is injurious, although Perold, a South African authority, recommends that varieties subject to "coulure," *i.e.*, bad setting, should not be cultivated for 2-3 weeks during flowering and setting.

He states that the soil will be kept warmer, and that berries will set better if the soil is not constantly kept loose. However important this may be, it is certain that there are other bigger influences concerned in "coulure," and should it be necessary for any reason to cultivate vines during setting, I do not consider that there is appreciable justification for deferring the operation.

Cabbage Moth.

Insect specimens submitted by the Clarendon Branch of the Agricultural Bureau were identified as the larvae of the Cabbage Moth, and the recognised method of control of this pest is to spray or dust with arsenate of lead preparations whilst plants are young.

Dusting with derris preparations—several of which are on the market—is also effective, and such treatment is to be preferred, especially in the later stages of plant development, owing to the fact that this insecticide is non-poisonous to humans.

If the specimen submitted was a representative one it is now too late to control the pest, the grubs having penetrated to the heart and beyond the reach of insecticidal dusts or sprays.

Treatment of plants from very early stages is essential for control of this pest.

Fertilizers for Potatoes.

"Scott's Bottom" Agricultural Bureau asks, "What would be the most profitable manure for potatoes? Tomato manure at the rate of 8cwts. to the acre, or 8cwts. bonedust, ½cwt. ammonia, and ½cwt. potash mixed per acre?"

Reply—In the absence of definite experimental evidence it is impossible to compare the two fertiliser dressings mentioned and, in fact, available information tends to suggest as best practice a dressing which differs from the two which have been quoted, *i.e.*, 3 to 6cwts of superphosphate plus 1cwt. of sulphate of ammonia per acre. Bonedust may be used as substitute for portion of the superphosphate if applied rather more heavily than superphosphate, but it should be noted that bone fertiliser is much slower acting than superphosphate. The latter fertiliser is able to fully benefit the crop in the season of application, but the beneficial effect of bonedust will be spread over several seasons.

So far there is little evidence that potassic fertilisers will increase yields, although there are indications that when used in the form of sulphate, quality of the potatoes is improved. The issue is not clear cut, however, and as potash is an expensive fertiliser heavy dressings could not be freely recommended. An occasional dressing of ½cwt. to 1cwt. of sulphate of potash per acre should be sufficient to ensure ample potash for production of quality crops, and until further experiments have given results it must be said that the need for potash is not marked.

Method of Applying Fertilisers.—The quick-acting fertilisers—superphosphate, sulphate of ammonia, and sulphate of potash—are best applied in the furrow at planting time. If bonedust is used with the object of long-range improvement in soil fertility this fertiliser may be applied broadcast some considerable time before planting.

Form of Potash Fertiliser.—Sulphate of potash is preferable to muriate of potash; it has been stated that whereas sulphate improves quality muriate may have the reverse effect.

Availability of Bonedust.—Bonedust is a relatively insoluble and slow-acting fertiliser, and the total amount of plant food in any quantity applied to the soil only becomes gradually available over a long period. Although some small benefit might accrue in the season of application of bonedust, the main benefits must be looked for in future seasons. For quick results always use superphosphate as a source of phosphoric acid.

FOREST MANAGEMENT.

The library of the Department of Agriculture has received from the publishers, Messrs. Chapman & Hall, 11, Henrietta Street, Covent Garden, London, W.C.2, a copy of a volume, "A Textbook on Forest Management," by M. R. K. Jerram, M.C., Assistant Lecturer in Forestry, University College of North Wales, Bangor, England. The object of the book is to bring to the notice of students all matters of primary importance relating to Forestry Management. It introduces to the student the more important problems which are involved, explains the principles on which their solutions are based and provides a framework on which a fuller knowledge may be built up. Published price, 10s. 6d. net.

MILLING CLASSES OF SHOW WHEATS, 1935.

[By C. E. Chapman, F.I.C., F.A.C.I., Deputy Government Analyst, and A. J. Farquhar, A.A.C.I., Analyst, Department of Chemistry.]

There were 43 samples of wheat entered for competition in the milling section of the 1935 Show of the Royal Agricultural and Horticultural Society.

The Society provided prizes for wheats which were classified into six classes, as follows:—

3003. Strong Flour Wheat, White, from district with an average annual rainfall of 16 inches or over.
3004. Strong Flour Wheat, White, from district with an average annual rainfall of less than 16 inches.
3005. Medium Strong Flour Wheat, from district with an average annual rainfall of 16 inches or over.
3006. Medium Strong Flour Wheat, from district with an average annual rainfall of less than 16 inches.
3007. Weak Flour Wheat, from district with an average annual rainfall of 16 inches or over.
3008. Weak Flour Wheat, from district with an average annual rainfall of less than 16 inches.

Some very interesting results were obtained from the samples, the results being dealt with under each class.

Each sample was prepared for milling by washing it with warm water and subsequently adjusting the moisture of the wheat to 15 per cent. In order to toughen the bran, a further 1 per cent. of water was added one hour prior to milling. The moisture content of the wheats when received in the laboratory varied from 12.0 to 15.1 per cent., the average being 12.8 per cent. A soft wheat, Sword (Laboratory entry R.R.), having a large number of broken grains, gave the highest result, 15.1 per cent.

The percentages of flour, bran and pollard were corrected to the same moisture basis. The chemical tests on the flour were calculated on flour containing 13.5 per cent. moisture, and the water absorption and baking tests were all carried out on a weight of flour equivalent to 85 grams of dry flour.

Class 3003.—The chemical and baking tests showed that Quality (C) was outstanding with regard to protein; it had the highest baking score and the greatest loaf volume, but the number of 2lb. loaves it would yield from a ton of flour was lower than that of the other Quality (B) (1,405 loaves). With the exception of Dundee, all the wheats of this Class must be regarded as satisfactory. The Dundee flour gave a low baking score, low loaf volume and weight, low protein, and a low water absorption for a hard wheat. It is inferior in every characteristic to the other sample of Dundee (I) in Class 3004. Taking into consideration the data made available by these tests, samples A and C were the best of this Class, although C had a lower water absorption than the majority of the samples in the Class.

Class 3004.—Entry H appeared to be the best of the Quality samples submitted, whilst the sample of Dundee was equal to the standard of this variety. All the samples of Dundee that have been tested in this Department have yielded flours of

inferior colour. All the flours in Classes 3003 and 3004 with the exception of entries D and K, were superior in baking quality to those in the same Classes which were tested last year.

Class 3005.—There are only four outstanding wheats in this Class, viz., entries M, N, R, and T. M baked into an excellent loaf of bread, but had the general fault of Ford flours—low water absorption. Nabawa (N and R) were lower in protein content, but gave more loaves per ton of flour. Penn and Pine Vale entries made loaves which were shell topped, Pine Vale being very pronounced in this respect.

Class 3006.—This Class was represented by two good wheats in entries U and V, both being high in protein and of average water absorption. Gresley was in many respects similar to the best types of the Ford variety. The Ford entry was low in protein. and Nabawa (PP) had a low protein content and gave an inferior baking test. The sample of Nabawa (PP) was of very low quality, being far below the average of this variety. It is interesting to note that the Champion Wheat and this entry were both grown at Narridy.

Class 3007.—Entries X and Z were the best of these samples. Sample Sword (RR) was very dirty and contained a considerable quantity of broken grain, which explains the low yield of flour obtained. The Waratah samples both had the usual poor baking characteristics of this variety. Pine Head and Grellet were poor wheats from a baking point of view, and had very low water absorptions.

Class 3008.—Entry Sword (JJ) appeared to be the best of this Class. Following this sample, in order of merit, were Ranee (AA), Turvey (II), then Ranee (FF) and Felix (GG) equal. Although entry Waratah (HH) had 12 per cent. of protein, it was of inferior baking quality, being no better than other samples of this variety containing about 8 per cent. of protein.

PELSHENKE AND BAKING TESTS.

It will be noted from the figures given in the table of results that the wholemeal fermentation time tests do not bear any relationship to the baking quality of the wheats. This is more noticeable in the tests made on the hard wheats.

CONCLUSION.

The milling tests and the chemical examination of the Competition wheats for the Royal Agricultural Society's Show are unquestionably of assistance in assessing the qualities of these wheats. It cannot be claimed, however, that these results are of much value in connection with the complex problem that is now receiving scientific attention by the Department of Agriculture and other institutions in order to obtain a general improvement in the quality of our F.A.Q. wheat. One must assume that the tests carried out in connection with the Show Wheats are done on the best wheats grown in the different districts of the State, and any records of the chemical tests can only be of value in making a comparison of the Show wheats of one season with those of another season.

The general improvement of the quality of wheat grown in South Australia can best be brought about by supplying farmers with improved varieties of seed wheats, which must be evolved by means of cross-breeding and careful selection, and subsequently growing these wheats in different parts of the State, in order to ascertain the varieties that are best suited to each district with its particular soil and climatic conditions.

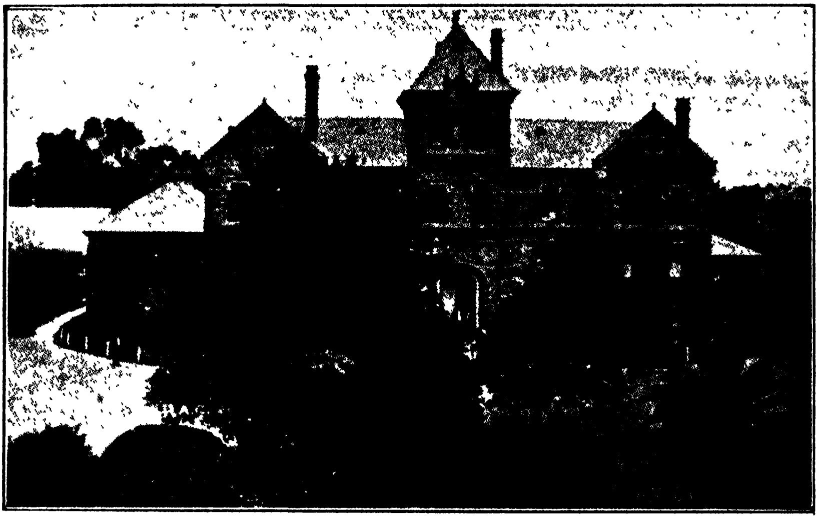
NOTE.—Owing to the transfer of entry T from Class 3006 to 3005, entry AA from Class 3007 to 3008 and entry FF from class 3008 to 3007, after the tests were completed, the photographs for these three entries are in other than their right classes.



ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)

F. COLEMAN, J.P.
A. E. V. RICHARDSON, M.A., D.Sc.
L. T. COWAN, B.Sc.
PROF. A. J. PERKINS
D. A. LYALL, ESQ.
W. J. ADEY, ESQ.

H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

THE PRINCIPAL,
Agricultural College,
ROSEWORTHY.

REPORT ON VISIT TO NORTHERN DISTRICTS SUBJECT TO GRASSHOPPER INVASION.

[J. Davidson, D.Sc., Waite Research Institute.]

During the period Monday, 9th September, to Tuesday, the 17th, the writer visited certain districts in the northern part of the agricultural areas and north-western pastoral areas, accompanied by Messrs. J. N. McGilp, of the Pastoral Board, and F. N. Ratcliffe, of the Council for Scientific and Industrial Research. The object of the trip was to visit localities which were infested with grasshoppers during the past two years, with a view to determining the endemic areas inhabited by the plague grasshopper.

No grasshoppers were seen in the pastoral country west of the Flinders Range, although several areas were visited which were invaded by winged swarms last season. Owing to the recent rains throughout the pastoral country and cool weather, scattered flying hoppers would not be active on the wing, even if present. The pastoralists in the various districts reported that none had been seen this spring.

The return route was through the Gawler Rangers, and no grasshoppers were seen. It was reported to me that small hatchings had been observed in the Kimba district. Certain areas in the Gawler Ranges appear to be suitable as endemic areas for the plague grasshopper. It is evident, however, that egg beds and hatching hoppers may pass unobserved, owing to the character of the country. The insect may be present in small numbers every year in suitable spear grass flats or other favourable situations. It is proposed to investigate these areas in greater detail.

Since returning to Adelaide a letter was received from Mr. Roy Brooke, of Nullabor Station *via* Coorabie. Mr. Brooke states that grasshopper swarms were observed during July and August on this station. Each swarm covered an area of some 500 to 700 acres. The earlier swarms travelled N.E., and later swarms travelled S.E. Favourable rains have been experienced over the eastern portion of Nullabor. It would appear that these districts may form an important endemic area for the migrating grasshopper. The recent invasion of the West Coast agricultural areas appears to have developed from this region and portions of the Gawler Ranges.

From information now available, it is unlikely that the West Coast agricultural districts will be subject to a widespread plague of grasshoppers this season. Hatching of hoppers may be expected in some districts as an aftermath of the recent infestation. Some flying hoppers may advance into these districts, later in the season, from the eastern areas of the Nullabor plain. A watch should be maintained in the agricultural areas of the West Coast, so that early control measures may be adopted should the necessity arise.

In the northern agricultural areas east of the Flinders Range and south to east of Port Augusta, young hoppers are present over a wide area. The infested districts extend from the south of Hawker, and east from Quorn and Wilmington across the plains. Although the hoppers extend over a relatively wide area, they are thinly scattered, and are not grouped in the characteristic dense swarms observed last season. Although the insects have hatched from three to five weeks ago, they are small, appear sluggish and variable in colour. Some dead hoppers were seen, and I was informed that many had died in some districts. The retarded development of the hoppers may be due to the lower temperatures during August and September. They will doubtless become more active as the weather becomes warmer. Owing to the thinly scattered distribution of the hoppers, control measures by baiting are more difficult at present, since the bait will have to be distributed over a relatively large area.

The travelling stock roads are one of the chief sources of infestation of crops in these districts. Mr. Barker, clerk of the district council of Wilmington, took me over the district, and hoppers had hatched freely from the stock road and other reserves. They had then advanced into neighbouring crops. This was noted on the properties of Mr. P. Cromer and Mr. E. L. Searle. Mr. Barker was distributing poison bait over the infested council's reserve near the town. Hoppers had also hatched in hard, bare patches in non-cultivated paddocks used for grazing purposes.

A few young hoppers have hatched since the recent rains. The numbers of hoppers found scattered over the area during my visit will not constitute a widespread serious plague, although they may be of local importance in the infested districts. "Baiting" measures should be carried out wherever practicable.

The thinly scattered distribution of the hoppers in these districts may be due to four considerations:—

(1) Small number of scattered egg pods laid last summer in these areas.

(2) Poor hatching of eggs due to inadequate early rains. Observations should be made to establish whether new hatchings occur in these districts following on the recent rains. This is important, since more extensive hatchings may lead to the development of denser local swarms with the approach of warmer weather.

(3) Many eggs have been destroyed by egg wasp parasites; *Scelio fulgidus* Crawford was observed to be active in several districts last season.

(4) The swarming phase of the species, which results in widespread plagues, may be less in evidence; the insects may be tending to the "solitary" or scattered phase. Other allied species may be present.

It is not possible to determine at present the part played by each of these different factors. Mr. D. C. Swan, Assistant Entomologist at the Waite Institute, is visiting the area early in October with Mr. E. L. Orchard in order to make more detailed observations on the situation. The endemic areas from which these districts become infested from time to time appear to lie north of this region, extending into the pastoral country along the ranges.(*)

The fundamental feature of "locust" plagues is that the particular species occur in a solitary, non-gregarious or non-migrating phase, in definite endemic areas. They develop into the gregarious swarming phase in certain years, and give rise to "plagues." It is of fundamental importance that the behaviour of our migrating grasshopper in this respect should be thoroughly investigated, and the endemic areas established.

---

* From investigations made by Mr. D. C. Swan in October it was found that the grasshoppers now present in the area consist mainly of a species of *Austroicetes*, probably *A. pusilla* Walk. The plague grasshopper (*Chortoicetes terminifera* Walk.) which was widely present on the area last season, is now poorly represented.

A COMPARISON OF BARLEY AND WHEAT AS A BASAL FOOD FOR PIGS.

[R. BAKER, R.D.A., Dairy Superintendent, Roseworthy Agricultural College.]

Over a great portion of the settled areas of South Australia, existing conditions are eminently suited to the raising of pigs for market. The climate in the main is ideal, suitable pigs are available for the foundations of a herd, and the fact that our farmers are able to grow large quantities of wheat and barley guarantees the supply of the most important basal foods, which, with the judicious use of suitable supplementary foods should make it possible to provide pigs in large numbers suitable to any market.

Low prices have been ruling for all cereals and the man on the land has of necessity interested himself in farm side lines. Pig raising is one of the most profitable of side lines, and the number of pigs raised has gradually increased until the demand for local requirements has been oversupplied. Fortunately, the market from time to time is relieved by the purchase of pigs for export, and values have been maintained at a payable level.

With a fully supplied market, pigs of an inferior type and feeding have become more and more difficult to dispose of at a price that would show some returns over food consumed and labour expended. Although the number of unsuitable pigs seen at our abbatoirs during the past twelve months has considerably decreased, there is still room for improvement of both type and feeding practice, particularly if our efforts to create a market overseas are to be successful. It must be realised that to become an exporting State success depends largely on continuous supply of pigs uniform in weight, and of a type suitable for trade.

That such pigs can be produced in South Australia is beyond doubt, and with some encouragement farmers for the most part should be able to succeed, especially when it is remembered that the correct breeds of pigs are now readily available, and the country is over-producing such valuable foodstuffs as wheat and barley.

Per medium of the press, public lectures, and export competitions, the type of pig required has been adequately defined, and it remains with the pig producer to carry out a definite system of breeding and feeding in order to compete in available markets against countries more favourably situated, or at least more advanced in the ways and means of exploiting export markets.

OUTLINE OF THE TEST.

At the suggestion of the Principal, Dr. A. R. Callaghan, feeding trials were instituted at the College piggery, the object being primarily, a comparison of the feeding of barley and wheat, with and without supplementary foods, to pigs of various breeding. The prime object was to assess the relative speed and economy in attaining a bacon weight of 160-180lbs. from the weaner stage, 40-60lbs. live weight. A second but subsidiary object was to ascertain the suitability of the carcass so fed for export, by submitting them to criticism by recognised men in the trade, both local and overseas.

FEEDING.

To provide a carcass carrying a wealth of lean meat the animal should be fed a protein rich ration, in other words a ration rich in flesh forming material. The basal foods, barley and wheat, used extensively in South Australia, are more or less deficient in this important nutrient and in order to provide a better balance, supplementary foods such as meat-meal, skim milk, and lucerne, all containing a relatively high percentage of protein, are necessary. Consequently, in addition to the feeding of barley and wheat alone, the supplementary foods, meatmeal, skim milk, and lucerne were used to comprise the following rations:—

Lot 1.—Barley.

Lot 2.—Barley and meatmeal, in the proportion of 100lbs. of barley and 5lbs. of meatmeal.

Lot 3.—Barley, skim milk, and lucerne, in the proportion of 100lbs. barley, 100lbs. skim milk, and 25lbs. of lucerne.

Lot 4.—Wheat.

Lot 5.—Wheat and meatmeal, in the proportion of 100lbs. of wheat and 5lbs. of meatmeal.

Lot 6.—Wheat, skim milk, and lucerne, in the proportion of 100lbs. wheat, 100lbs. skim milk, and 25lbs. of lucerne.

As far as was practicable all pigs were given as much food as they would consume daily, the grain in all cases being crushed. In Lots 2 and 5 the meat-meal was mixed with the grain before feeding; in Lots 3 and 6, the skim milk was mixed with the grain in the feed trough, so that all the pigs in the pen would obtain, as near as possible an equal share, the lucerne being fed during the day. An ample supply of drinking water was provided at all times. Throughout the test, grain of a similar quality was fed, the barley was rather pinched carrying a fairly high percentage of fibre, and the wheat was an average sample.

BREEDING.

The test was carried out with pigs of different breeding. This was necessary to get numbers required for the experiment and also to ascertain the relative merits of different breeds fed on similar rations.

Breed.	No.	No. of Litters.	Date of Birth.
Berkshire (Old Type)	6	2	4 on 16th October, 1933 2 on 29th October, 1933
Large White x Berkshire	12	2	6 on 30th October, 1933 6 on 13th November, 1933
Tamworth x Berkshire	6	1	30th October, 1933
Large White x Mid York	6	1	29th October, 1933
Large White x Tamworth x Berkshire	6	1	8th November, 1933

ARRANGEMENT OF PENS.

The 36 pigs were divided into six feeding lots, each pen consisting of 1 Berkshire, 2 Large White x Berkshire, 1 Tamworth x Berkshire, 1 Large White x Mid York, and 1 Large White x Tamworth x Berkshire. The pens were so arranged to make the initial total weight of each pen as near as possible alike.

Lot 1.	272lbs.
Lot 2.	278lbs.
Lot 3.	283lbs.
Lot 4.	276lbs.
Lot 5.	273lbs.
Lot 6.	275lbs.

In carrying out the test all pigs were weighed prior to the commencement of feeding, and in order to ascertain progress of development the pens were weighed at fortnightly intervals. Daily records were kept showing the consumption of food in each pen. On reaching bacon weight individual pigs were sent to the Government Produce Department at Port Adelaide, where they were slaughtered. Here cold dressed weights were recorded, and the carcasses criticised as to their suitability for export. They were then held in cold stores until the completion of the test, before being sent to England for further comment and sale.

Arrangements demanded the pigs to be slaughtered on certain days, and for this reason a standard weight for the finished animal could not be adhered to. It will be noticed also from the final figures that a number of pigs were disposed of at a weight lower than was originally intended; this was due solely to the prolonged feeding period and the reluctance of pigs so fed to reach bacon weight.

Had the pigs been held until fully developed the daily increase in a number of cases would have been lower than the figures shown in the completed table This is particularly so with pens fed simple rations, *i.e.*, wheat and barley. It also applies, but to a much lesser degree, to the pen of pigs fed barley and meatmeal. In this pen two individuals failed to reach the desired weight by the time it was decided to complete the test, a period of 142 days. Actually the data record the increase in weight of the various groups within a certain time limit.

In all, 31 pigs were sent overseas; of the remainder, two were held at the depot and disposed of locally and three were slaughtered on the farm. The following table shows in detail the figures at the completion of the test:—

Due to the fattening propensity of the individual under different rations, the range in time when pigs reached bacon weights varies greatly; still it will be noticed that the range has a definite relationship to the composition of the ration used.

In the feeding of barley or wheat, the time required is relatively much longer than when supplements such as skim milk and lucerne are used; this is to be expected, for both the latter have high protein content and are greatly relished by pigs. In the cases of both wheat and barley, time of feeding ranged from 130 to 142 days, with the respective averages of 137.83 and 137.16 days. With the addition of skim milk and lucerne the duration of feeding was reduced to from 58 to

100, an average of 86 days in case of barley, and with wheat from 58 to 100, an average of 79 days.

The reduction in time of feeding is attributed chiefly to the better balanced nature of the ration, but also in some measure to the increased palatability of the foods when used in addition to basal grain, which leads to better assimilation of all ingredients. The rapidity of development was particularly noticeable in pigs few skim milk and lucerne.

The addition of meatmeal, although it increased the protein of the ration, it did not bring about a very marked reduction in time of feeding with barley, the range being from 114 to 142, an average of 130.33 days, but with wheat an appreciable reduction was noticed, from 86 to 114, an average of 104.66 days.

The highest daily increase was obtained by pigs on a ration of wheat, skim milk and lucerne, they showed a mean increase of 1.662lbs. per day, ranging from the Large White x Mid York, 1.828lbs. per day to the Berkshire, 1.470lbs. The ages of these two pigs were identical, but the former, according to initial weight was more matured at the commencement of feeding and during the first six weeks increased rapidly, showing the remarkable figure of approximately 2¼lbs. increase in weight, or a little over 1½lbs. of pork per day, during the second fortnight. The Large White x Berkshire also showed early maturing tendencies under this class of feeding, and pigs of this breeding were very little behind at the completion of the test. The Large White x Tamworth x Berkshire, on the other hand, was rather slow in developing during the initial stages, but fattened rapidly towards the end. The pigs fed barley, skim milk and lucerne, although showing a satisfactory mean increase of 1.481lbs. per day did not compare quite as favourably with those fed wheat, skim milk, and lucerne. In this instance the Tamworth x Berkshire showed the greatest daily increase, 1.655lbs., while the Large White x Mid York recorded the lowest returns, 1.240lbs. Here again the Tamworth x Berkshire was more mature at the commencement of the test, and although only a day younger than the Large White x Mid York, its capacity for assimilating food and its ability to fatten was greater. This individual capacity for development is again demonstrated with the two Large White x Berkshires, whose difference in age was 14 days, with the initial weight of the younger 1lb. heavier than the elder and their respective rates of increase 1.604lbs. and 1.260lbs. As in the wheat pen, the Large White x Tamworth x Berkshire was again rather slow at the beginning of feeding, but finished above the average of the pen.

MEATMEAL AS A SUPPLEMENT.

It is recognised that both the basal foods, barley and wheat, are deficient in protein, and used alone are not sufficient to satisfy the feeding requirements of present-day market pigs. With this fact in view it was thought that by the addition of meatmeal, a food containing a high percentage of digestible protein, the increase in growth of the pig would be influenced.

From the results obtained in this experiment, this supposition was clearly proved. By the mere addition of meatmeal as a supplement to wheat in the ration, a mean daily increase of 0.497lbs. was obtained from pigs fed on this ration over and above the increase obtained from wheat alone. In the cases where barley was used in the ration the increases due to the addition of meatmeal were not so noticeable, and, in fact, were very disappointing.

This is difficult to understand in view of the fact that barley showed to advantage over wheat when fed alone. The conditions might be attributed to the unpalatable and fibrous nature of the barley, which was not altered to any marked extent by the addition of meatmeal.

It will be obsered that in both groups fed meatmeal the Tamworth x Berkshire than wheat, the respective mean daily being .809lbs. and .748lbs.

COMPARISON OF WHEAT AND BARLEY FED ALONE.

From the results obtained the feeding of barley showed slightly better returns than wheat, the respective mean daily being .809lbs. and .748lbs.

Apparently the difference between the two groups of pigs would have been greater had all the individual pigs been allowed to continue feeding to bacon weight. Four pigs from those on the plain ration of wheat were disposed of before they had reached bacon weight, whereas only two pigs from those on the barley ration were slaughtered before they had reached bacon weight. In passing it is worthy of notice that the Tamworth x Berkshire and the Large White x Tamworth x Berkshire pigs from the group on the barley ration increased more rapidly than pigs of other breeding. Among the pigs fed on wheat ration the Tamworth x Berkshire and the Large White x Mid York matured slightly ahead of the pigs of other breeding.

RATE OF MATURITY.

The rate of increase of different breeding, irrespective of the system of feeding, is difficult to follow from figures obtained. In fact, it is impossible to state with any certainty whether the pigs of any particular breeding show any outstanding advantage over others with regards to early maturing tendencies. The final figures do not vary to any extent, there being only .08lbs. between the highest and lowest. Had feeding continued in all cases to a bacon weight it may have been possible to show more definite results; the Large White x Mid York would undoubtedly return the highest rate of maturity, while the lowest figures would probably be represented by the Large White x Tamworth x Berkshire.

QUANTITIES OF FOOD CONSUMED.

Table II. shows the total quantity of food consumed by the different groups of pigs, also the amount of food required to produce a pound of increase, and the quantity consumed per day, expressed as food and dry matter.

The figures quoted in the table demonstrate that the total quantity of food consumed daily by the different pens depends mainly on the bulkiness of the ration. When foods containing a high proportion of water, such as skim milk, lucerne, &c., are fed in conjunction with grain, the total weight of food consumed each day is considerably higher than when grain alone is used, the water content of the food taking the place of part of that utilised in the ordinary way, and it is doubtful whether the combined weights of water and "dry matter" would vary to any great extent in different systems of feeding. This is illustrated by expressing the rations on the basis of dry matter.

The quantity of dry matter consumed per day by the different groups of pigs indicates that by the use of palatable supplements, greater use is made of the grain; in fact, the assimilation of all foods fed is increased. This is borne out by the quantity of dry matter that is necessary to produce one pound of increase. In addition to the palatability of a ration consisting of barley or wheat with skim-milk and lucerne, the protein content has been increased, creating a better balance to the grain, thereby providing a food that encourages the growth and the development of lean meat in the animal.

A comparison of the feeding of barley and wheat under corresponding conditions points in favour of wheat, for in each instance less wheat is required to produce 1lb. of increase. This in all probability is due to the nature of the barley used in the test. As pointed out it contained a fairly high percentage of fibre when compared with that of wheat.

It is of interest to note that each group of pigs supplied supplementary foods showed a decrease in the amount of dry matter required to bring about one pound of increase when compared with those fed grain alone, yet with the exception of the group fed barley and meatmeal, there was an increase in the quantity of dry matter consumed each day. The extent of the difference is illustrated in Table III.

TABLE III.

Ration.	Consumed per Day.	Increase.	Decrease.	Consumed per lb. of Increase.	Decrease.
	Lbs.	%	%	Lbs.	%

Wheat, Skim Milk and Lucerne...	5·45	64·15	—	3·31	25·78

COST OF FEEDING.

For the purpose of estimating the cost of feeding the different rations the following prices have been taken as representing approximately those ruling during the progress of the test:—

Wheat, 2s. 3d. per bushel, or .45 pence per lb.
Barley, 2s. per bushel, or .48 pence per lb.
Meatmeal, 17s. per 140lbs., or 1.45 pence per lb.
Skim milk, 1d. per gallon, or .1 pence per lb.
Lucerne, 30s. per ton, or .16 pence per lb.

The figures in Table IV. represent the value of food consumed per day and the value of food necessary to produce a pound of increase and a pound of pork. In estimating the difference between "increase" and "pork" a 30 per cent. decrease has been recognised.

TABLE IV.

Ration.	Showing the Cost of Feeding.				Cost per 1lb. of—

Total	—	—	—	3·050	1·857	2·652

The average cost of food per pig per day in the various pens shows an increase as the food value and the palatability increases. As already pointed out, by increasing the palatability a greater quantity of food is consumed, but better assimilation of food follows, and this is clearly reflected in the decreased cost of food necessary to produce a pound of pork. The percentage differences between costs are shown in the following table:—

TABLE V.

Ration.	Cost of Food per Day.		Cost of Food per 1lb. of Pork.		
		Increase.		Decrease.	Increase.
	d.	%	*d.*	%	%
Barley	2·180	—	3·88	—	—
Barley and Meatmeal	2·354	7·98	3·991	—	2·86
Barley, Skim Milk and Lucerne	3·54	53·85	3·285	15·34	—
Wheat	1·674	—	3·207	—	—
Wheat and Meatmeal	2·308	37·87	2·913	9·17	—
Wheat, Skim Milk and Lucerne	3·050	82·19	2·652	17·31	—

The value of increase over cost of food consumed by the various groups is shown in Table VI. In estimating the value of increase an average price of 5.547 pence has been taken. This figure represents the average price per pound of pork obtained from the net returns of pigs exported, after all charges and exchange were adjusted.

Lot 6.—					
Wheat	2,452	778	120 6½	251 9	131 2½
Skim Milk	2,452	—	—	—	—
Lucerne	613	—	—	—	—

A comparison of the different pens shows the advantage of wheat feeding during this trial over a corresponding barley ration. This will be more readily understood when the difference in weight of a bushel of wheat and barley is taken into consideration, actually 1lb. of wheat cost .45d. against barley at .48d. for feeding purposes.

VALUE OF A BUSHEL OF GRAIN FED TO PIGS.

From figures quoted in previous tables it is possible to estimate the value of a bushel of barley or wheat fed to pigs under the conditions of the test.

TABLE VII.

Ration.	Cost of Grain Fed.		Value of Grain after Feeding to Pigs.		Per Cent. Increase by Feeding to Pigs.
	Per Bush. *s. d.*	Per Lb. *d.*	Per Bush. *s. d.*	Per Lb. *d.*	%
Barley	2 0	·48	2 10·25	·68	42·71
Barley (with Meatmeal)	2 0	·48	2 7·63	·63	31·79
Barley (with Skim Milk and Lucerne	2 0	·48	3 9·28	·90	88·66
Wheat	2 3	·45	3 10·65	·77	72·77
Wheat (with Meatmeal)	2 3	·45	4 7·01	·91	103·74
Wheat (with Skim Milk and Lucerne	2 3	·45	5 5·52	1·09	142·66

The figures in the column "Value of grain after feeding to pigs," are estimated on the average net price of all pigs sold overseas, 5.547 pence per lb. of pork. At this price an appreciable increase in the value of a bushel of grain is recorded in all cases.

The results from the ration of barley and meatmeal are somewhat disappointing when compared with barley alone; this appears to be due to two factors—one, the unpalatable nature of the barley, and two, the increased cost of feeding meatmeal. With a normal sample of barley it would be reasonable to expect an advantage by feeding meatmeal, as noticed in the difference of the results from the rations, wheat, and wheat and meatmeal. On the other hand, the addition of skim milk and lucerne with barley shows a decided advantage.

With regard to the pigs fed wheat, the addition of a palatable and nutritious food is reflected by a marked increase in the value of the grain consumed. Where skim milk and lucerne were used the results are outstanding.

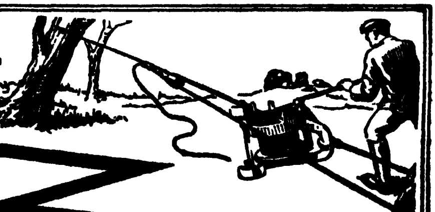
LOSSES IN DRESSING.

In the following tables the losses in dressing are shown, representing the difference between "farm weight," the weight immediately prior to leaving the farm without any interference in routine feeding, and a cold dressed weight recorded after the animal heat has left the body prior to freezing.

It will be noticed that the losses are greater where the pigs received barley as the basal food, with the greatest loss (30.51 per cent.) when skim milk and lucerne were fed in conjunction. Similarly with the pigs on a ration of wheat, the highest figure (28.49 per cent.) was obtained where the skim milk and lucerne were used in addition. This may be due to greater bulkiness and the presence of a higher percentage of water in the ration; being more bulky the animal would be carrying a greater quantity of undigested food at the time of slaughter. No special preparations were followed for killing, the pigs being slaughtered approximately 12 hours after leaving the farm. The best weights after slaughter were obtained when meatmeal was used as the supplement in both the wheat and barley rations. In such cases the bulk of the ration was less as a result of the meatmeal supplement, 27.91 per cent. and 28.66 per cent. respectively.

With pigs of different breeding the Berkshire rank the lowest, 28.31 per cent., and the Large White crossed with the Tamworth x Berkshire the highest, 29.89 per cent. It will also be seen that where the Berkshire represents half or more of the breeding the losses in dressing are lower. This may be due to the higher percentage of fat being carried by this class of animal over types that possess a wealth of lean meat which contains a higher percentage of water.

The average of all pigs, 29.09 per cent., represents very closely the recognised 30 per cent. difference between farm and dressed weights at the factory.



TEARING THEM OUT

is the regular job of the Monkey Grubber: in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a [illegible] truck, and worked in the same manner as a boat is rowed. It develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

CRITICISM OF CARCASSES.

The carcasses of all pigs sent overseas were criticised as to their suitability for export, first at the Government Produce Department at Port Adelaide by Mr. Henschke, secondly, on arrival in England by Mr. Whitney, of the Stockbreeders Meat Company.

Before reviewing the comments it would be advisable to give Mr. Whitney's definition of what is required to meet the demands of the United Kingdom trade in both pork and bacon.

The Porker.—The pigs should be clean, well dehaired, and as near white finished carcasses as possible. The skin should be smooth and free from coarse wrinkles, the main object of design and general appearance, including finish, to be attractive. The hams should be well rounded and reasonably covered with fat, full of meat as possible right down to the hocks, with short and fine leg bones.

The loins should be a good length, also broad and full of flesh; that is to say, with a large eye piece of lean meat, with a fair covering of fat to the size of the carcass. The bellies should be compact with not too much leaf and well streaked with lean, also with a reasonable proportion of fat.

The shoulder should also be compact with the blade bones well set in, the whole tapering towards a small neck and fine short boned front legs. The size of the head should be in proportion to the weight of the carcass—the smaller the better at all times.

The fats should be white, firm and not oily, and only moderate in proportion to lean so that trimming is avoided when the carcasses are cut.

The 60/80lb. pigs are always the best sellers to the retail butchers. The 80/100lbs. also meet a fair demand, but they usually make slightly less money.

Although porkers are usually graded up to 120lbs., as soon as 100lbs. weight are exceeded values as a general rule decline in accordance with weight, owing to the fact that a large percentage of the retail butchers will not handle a pig over 100lbs. Buyers are therefore hesitant to purchase at this weight; at the same time such pigs cannot be properly classed as baconers.

The Baconer.—The pig should be clean, well dehaired, and as near white finished carcasses as possible. The skin should be smooth and free from coarse wrinkles. The hams should be long, wide, and full of meat right down to the hocks, with short and fine leg bones. The backs should be a good length, also broad and full of flesh, with a high proportion of lean meat to fat. They should have long level sides tapering to proportionately light shoulders, the shoulders being compact with the blade bones well set in, with a small neck and fine short-boned front legs. The size of the head should be in proportion to the weight of the carcass, the smaller the better at all times, the whole having the effect of a light fore-end. The fat should be white, firm, and not oily, and only moderate in proportion to lean, so that trimming is avoided when the carcasses are cut. The bellies should be well streaked with lean meat, with not an excess of leaf fat.

The general public dislikes too much fat in pork, bacon, and ham because of waste. What fat there is must be firm and not oily.

With these definitions in mind the criticisms of the various carcasses can be better understood.

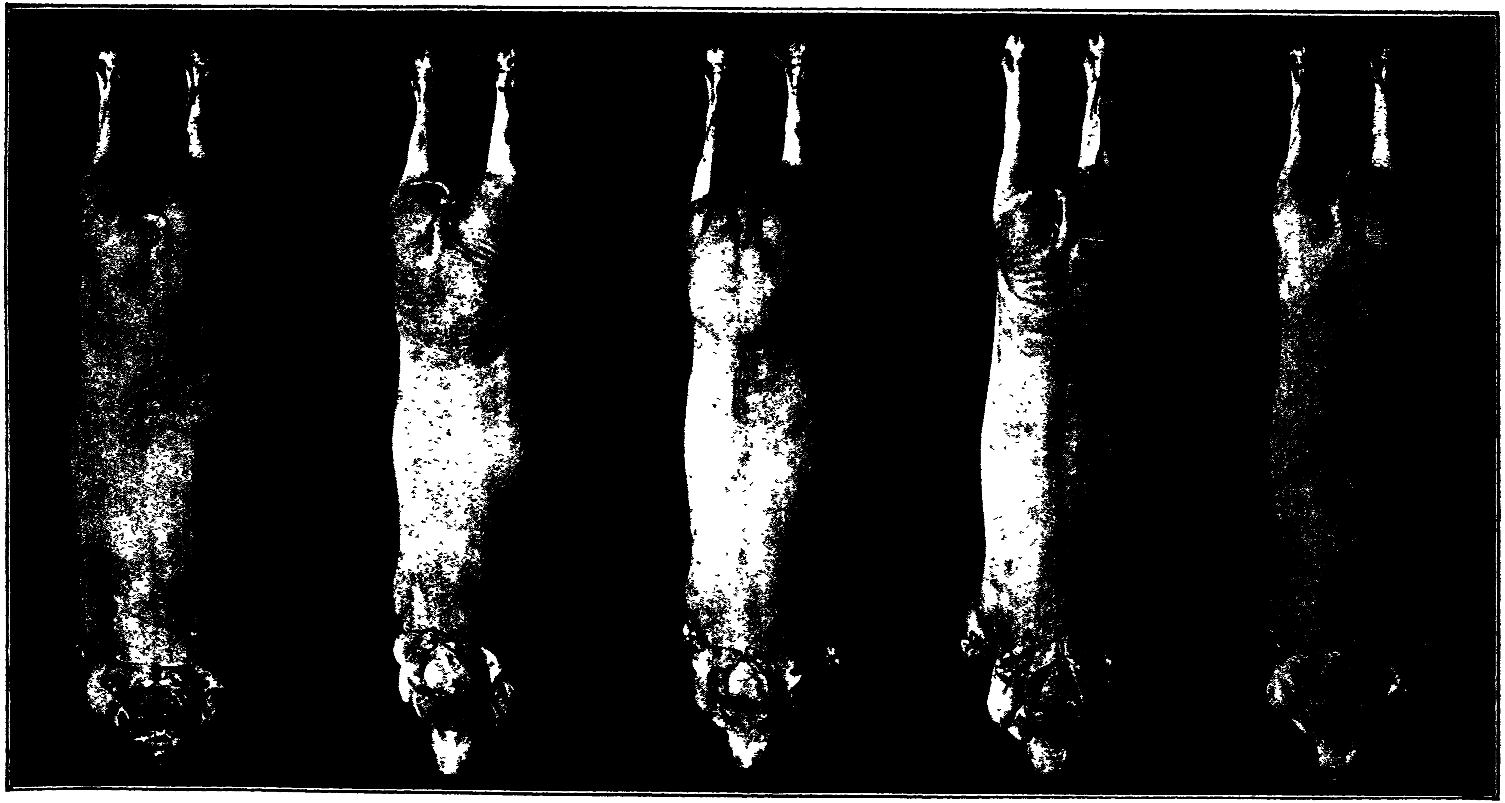
CRITICISM OF CARCASSES.

Lot 1.—Barley.

Berkshire K61	Local:	Wonderful hams, otherwise too short and fat for trade purposes.
	London:	Very good pig of the type, with very good hams, but no length in the loins and very heavy in the shoulder, generally speaking too fat and wasteful for the trade.
Large White x Berkshire	Slaughtered on the farm.	
Large White x Berkshire K63	Local:	Good porker, conformation and quality right, also carrying a clean, white skin.
	London:	Satisfactory.
Tamworth x Berkshire 249	Local:	Conformation and quality right, skin showing black patches and badly marked from fighting.
	London:	Good hams, rather wasteful and heavy in the shoulder, would cut too fat.
Large White x Mid York K60	Local:	Good bacon pig, nice length of middle, skin clear and white.
	London:	Satisfactory, but a little wasteful.
Large White x Tamworth x Berkshire K62	Local:	Conformation and quality right, skin showing mottles down the back.
	London:	Very good quality and conformation, but inclined to be a little too fat.

Lot 2.—Barley and Meatmeal, 100-5.

Berkshire 250	Local:	Good hams, otherwise very coarse, showing a bad skin.
	Disposed of Locally.	
Large White x Berkshire 389	Local:	Conformation and quality right, skin showing a very high colour.
	London:	Very good baconer, inclined to be a little wasteful.
Large White x Berkshire 390	Local:	Conformation and quality right, badly marked through fighting.
	London:	Good baconer, altogether satisfactory.
Tamworth x Berkshire B69	Local:	Conformation and quality right, but showing a very bad skin, brown patches practically all over the carcass, especially hams.
	London:	Satisfactory.
Large White x Mid-York 388	Local:	Conformation and qaulity good, but skin showing red down back and on flanks, marked with fighting.
	London:	Very satisfactory type of baconer.
Large White x Tamworth x Berkshire	Slaughtered on the farm.	



SPECIMENS OF THE 31 CARCASSES SENT TO LONDON FOR CRITICISM IN CONNECTION WITH THESE EXPERIMENTS

1 Old-time Australian Berkshire—unsuitable for export. 2, 3, 4, 5—Long, narrow types (Large White and Tamworth) were used as sires, and the short, thick types (Berkshire and Mid York) as dams.

2. Large White–Berkshire. 3. Tamworth–Berkshire 4. Large White-Mid York. 5. Large White on Tamworth–Berkshire.

Lot 3.—Barley, Skim Milk, and Lucerne, 100-100-25.

Berkshire 240	Local:	Showing good hams, otherwise coarse, especially shoulders and jowl, carcass too fat and skin rough.
	London:	True to type of pure Berkshire, having very good hams, but cannot be classed as good baconers in the United Kingdom, too short in the back and too wide, too heavy in the fore ends, and would cut far too wasteful.
Large White x Berkshire 239	Local:	Good conformation, but skin showing small haemorrhagic spots over the carcass.
	London:	Very good baconer, inclined to be a little wasteful, better in this respect than 389, fed barley and meatmeal.
Large White x Berkshire 243	Local:	Nice light baconer, showing good conformation and quality right, skin showing slight haemorrhage.
	London:	Excellent quality, suitable for United Kingdom trade, conformation and condition good.
Tamworth x Berkshire 232	Local:	Good hams and length of loin, rather fat, skin very bright.
	London:	Satisfactory throughout, not too wasteful.
Large White x Mid-York 242	Local:	Ideal bacon pig, good ham, nice length of loin, quality good, not too fat, good skin.
	London:	Very good type of baconer, not too wasteful.
Large White x Tamworth x Berkshire 238	Local:	Good conformation, but showing a poor skin, black patches and red blotches on back and shoulders.
	London:	Satisfactory type of baconer.

Lot 4.—Wheat.

Berkshire	Slaughtered on the farm.	
Large White x Berkshire K64	Local:	Light bacon pig, conformation and quality good, showing a very bright white skin.
	London:	Good conformation and quality, inclined to be a little too fat.
Large White x Berkshire K65	Local:	Light bacon pig, conformation and quality good, showing a very bright and white skin.
	London:	Good conformation and quality, inclined to be a little fat.
Tamworth x Berkshire 391	Local:	Good bacon pig, showing dark patches characteristic of this cross, no red discolouration.
	London:	Very good baconer, not too heavy in the fore ends and not wasteful, showing a fair amount of Tamworth strain in length of lean meat.
Large White x Mid-York 392	Local:	Nice bacon pig, but carrying a high colour.
	London:	Satisfactory bacon pig.
Large White x Tamworth x Berkshire K66	Local:	Good porker, skin showing a slight red blemish on the forequarter.
	London:	Excellent quality, very suitable for United Kingdom trade, conformation and quality very good.

Lot 5.—Wheat and Meatmeal, 100-5.

Berkshire 248	Local:	Excellent hams, quality too fat and very rugged in the fores, too much jowl.
	London:	Excellent pig of the pure Berkshire, very good hams, but cannot be classed as a good baconer in the United Kingdom, too short in the back and too wide, too heavy in the fore ends, and would cut far too wasteful.
Large White x Berkshire 244	Local:	Showing good hams, good loins, rugged in the fores, jowl prominent, skin showing red blemish down the back.
	London:	Very good baconer, inclined to be a little too wasteful.
Large White x Berkshire 245	Local:	Good conformation and quality, jowl slightly prominent, a very white, clear skin.
	London:	Good baconer, altogether satisfactory.
Tamworth x Berkshire 247	Local:	Good quality, fair conformation, skin showing brown patches on hams and flanks.
	London:	Satisfactory type of baconer.
Large White x Mid-York 237	Local:	Nice carcass, showing good conformation, jowl prominent, skin very bright and clear.
	London:	Satisfactory type of baconer.

Lot 5—*continued.*

Large White x Tamworth x Berkshire 246	Local:	Good conformation and quality, skin showing red blotches down the back.
		Disposed of locally.

Lot 6.—Wheat, Skim Milk, and Lucerne, 100-100-25.

Berkshire 241	Local:	Wonderful hams, otherwise too short and thick for bacon.
	London:	Excellent pig, true to type of the pure Berkshire, very good hams, but to be classed as a good baconer in the United Kingdom, is too short in the back and too wide, too heavy in the fore ends, with cuts far too wasteful.
Large White x Berkshire 234	Local:	Showing good hams and long loins, skin very bright, but carcass too fat and showing too much jowl.
	London:	Of nice quality, with good conformation, not too wasteful, a good type.
Large White x Berkshire 233	Local:	Conformation good, but carrying too much belly fat, skin showing small red spots on loin and shoulder.
	London:	Very good baconer, but inclined to be a little wasteful, but better than Large White x Berkshire fed wheat and meatmeal.
Tamworth x Berkshire 236	Local:	A good bacon pig, showing good hams, a long loin, not too fat, but skin showing small haemorrhagic spots.
	London:	Very good baconer, not too heavy in the fore ends, showing a fair amount of Tamworth strain in length of lean meat.
Large White x Mid-York 231	Local:	Good hams, long loins, skin rather red, excess of fat along the back, especially at the flanks.
	London:	Satisfactory type of baconer.
Large White x Tamworth x Berkshire 235	Local:	Good hams, nice length of loin, skin showing a very high colour, jowl prominent, carrying excess of belly fat.
	London :	Satisfactory type of baconer.

CLASSIFICATION OF PIGS EXPORTED.

Berkshire.—Four pigs exported. These were criticised, both in South Australia and England, as being unsuitable for trade purposes, being heavy at the shoulder and too short and thick in body; they were also far too wasteful when cut up. Otherwise they were described as having excellent hams.

Large White x *Berkshire.*—Eleven pigs exported. One of these reared on barley, skim milk, and lucerne was classed as excellent, complying with all characteristics that go towards an ideal type. Four pigs were classed as very good and satisfactory, being of good conformation and not wasteful when cut up; these were reared on barley, barley and meatmeal, wheat and meatmeal, and wheat, skim milk, and lucerne respectively. Six pigs were classed as very good, but a little wasteful; although of good conformation they were carrying a little too much condition in various parts of the body, particularly the shoulders and head; in this case the pigs were fed barley and meatmeal, barley, skim milk and lucerne, wheat and meatmeal, wheat, skim milk and lucerne, and two wheat alone.

Tamworth x *Berkshire.*—Six pigs exported. Five of these were classed as very good and satisfactory, having long bodies, good hams, and light forequarters. The pig fed on barley, although classified as good, was too heavy in the shoulder and would cut too fat.

Large White x *Mid-York.*—Six pigs exported. Five of these were classed as very good and satisfactory; the pig fed on barley, very good conformation but a little wasteful in cutting up.

Large White x *Tamworth* x *Berkshire.*—Four pigs exported. One of these fed on wheat was classed as excellent, being light in the shoulder, long in the body, good hams, and would cut up without waste; two, one of which was fed on barley, skim milk, and lucerne, and the other on wheat, skim milk, and lucerne, were described as very good and satisfactory; and the pig fed on barley, as very good, but a little wasteful.

IN CONCLUSION.

Although the final figures of the feeding test give considerable information and subject for thought, the termination of the trial before all pigs had reached a bacon weight has introduced one or two debatable points, the figures not being sufficiently complete to make a true comparison possible in all cases, and due allowance should be made when comparisons are attempted.

In the groups fed barley, barley and meatmeal, and wheat, 3, 2, and 4 pigs respectively completed their feeding while still short of the desired weight. Had feeding continued with the same rate of increase per individual, a further seven to eight weeks would have elapsed before the last pig would have reached 160lbs. live weight; by terminating the test early the pigs in three pens referred to show slightly higher returns than would otherwise be the case.

The sample of barley used during the test was of rather poor quality, the grain being shrivelled and carrying a fairly high percentage of fibre, with the result that final figures were somewhat misleading. For comparison a further series of feeding trials has been instituted on somewhat similar lines, using a better quality grain, and no doubt results will show to advantage over the present series.

DEDUCTIONS.

1. In the feeding of pigs, rations balanced by the addition of appetising foods return greater gains than those that are unbalanced, dry and unpalatable, as shown by the supplementing of grain with skim milk and lucerne.

2. Meatmeal can be fed to advantage with wheat; with barley, results were disappointing. It was expected that by improving the protein content final figures would have been somewhat in the same proportion as meatmeal and wheat, particularly as barley showed to greater advantage than wheat when fed alone.

3. The amount of food, in terms of "dry matter," consumed per day increases with the palatable nature of the ration, but decreases in quantity required to produce 1lb. of increase.

4. The use of supplementary foods increases the value of food consumed per day, but with one exception, meatmeal and barley, decreases the cost of producing 1lb. of pork.

5. With pork at 5½d. per lb., the mean value of increase per pig over food consumed is as follows:—Barley, 10s. 8¾d.; barley and meatmeal, 10s. 0¼d.; barley, skim milk, and lucerne, 16s. 6½d.; wheat, 14s.; wheat and meatmeal, 18s. 1d.; and wheat, skim milk, and lucerne, 21s. 6½d.

6. With pork at 5½d. per lb., barley fed to pigs alone, with meatmeal, and with skim milk and lucerne, would be worth respectively 2s. 10¾d., 2s. 7½d., and 3s. 9¼d. per bushel; whereas wheat fed in similar manner would be worth 3s. 10½d., 4s. 7d., and 5s. 5½d. per bushel.

7. The mean difference of 29.09 per cent. between live weight on the farm and cold dressed weight represents very closely the recognised 30 per cent. loss in dressing.

8. Local and overseas authorities agree on the main characteristics of type, namely, light fore-ends, long bodies, and well developed hams; the greatest fault is the carrying of excess fat, particularly at the shoulder and along the back, for the reason that it is too wasteful when cut into joints or pieces.

9. Conformation of the ham is important in pigs for export, a characteristic that is not very often associated with the long lean breeds, as the Large White and Tamworth.

10. Colour of carcass, though important, is not stressed by the London critic, beyond stating they should be well dehaired and as near white as possible. This may be due to the fact that bacon, and not pork, types were under review.

By careful attention to breeding pigs light in shoulder, long in the bodies, and well-developed hams, and the judicious use of palatable and nutritious supplements to barley and wheat such as skim milk and lucerne, and to a lesser extent meatmeal, economic results can be obtained on the export market.

SEED WHEAT FROM CROP COMPETITIONS.

In Wheat Crop Competitions, conducted in the undermentioned Districts the following Competitors exhibited crops which, in the opinion of the Judge at the time of inspection, should produce grain suitable for seed purposes.

ANNUAL REPORT ON PASTURE WORK, KYBYBOLITE, 1934-35.

[By L. J. Cook, R.D.A., Manager.]

Another comparatively good pasture season was experienced during 1934-35, and of 602 acres of fields and plots that have been used as pasture during recent seasons, 324 acres (54 per cent.) of them recorded increased carrying capacity over the previous season, and the majority of the other fields exceeded the average for the past seven seasons. Consequently a further small increased number of livestock was carried on the Farm for the year, and approximately 100 acres of pasture were mown and conserved as ensilage or hay, yielding an increased conservation of 60 tons of each class of fodder.

Throughout the agricultural year—1st April, 1934, to 31st March, 1935—an average of 1,646 sheep and 145 cattle has been kept, as against 1,626 sheep and 143 cattle during the previous 12 months, showing an increase of 20 sheep and 2 cattle. 192 acres of temporary pasture were available during the season, and 113 acres were sown to crops. Hence 794 acres of pasture, with the stubble feed of 113 acres, have provided feed for 1,646 sheep, and 83 head of growing cattle wholly throughout the season, as well as full pasturage for 48 milking cows during the pasture growing period, and portion of their feed during the balance of the year. Also 24 horses have had part-time grazing. Besides the above grazing 140 tons pasture growths were made into silage, and 82 tons meadow hay were made and stored from various fields. 130 acres of the general pasture fields were not top dressed this season, whilst 286 acres of these pasture fields received 90lbs. 45 per cent. superphosphate per acre.

Well grazed *Phalaris tuberosa* and Subterranean Clover pasture on its fifth season of growth.

THE SEASON.

A splendid opening rain of 1½in. was received during the first few days of April, and this was followed by a further 1½in. distributed over the second and third weeks of that month, which caused a first-class germination and a quick early growth of pasture plants. This opening was followed by an unusually dry winter, only 8 points being received in May, and 57 points in June, which naturally checked growth of plants. However, well fertilised pastures responded so well to the early rains that sufficient grazing was available for all stock, and hand-feeding was not required. Moreover, it ensured good sweet short pastures during this period, and consequently good health amongst the stock. Very useful rains were received in July, ¾in. less than the average, and August rains were ½in. below average, which allowed pasture plants to maintain healthy growth, without practically any saturated conditions. The September, October, and November rains were really good, registering more than 2in. above the average for the spring, and caused a very fine finish to the pastures. On account of the somewhat late start of these spring flush growths, the growths of Subterannean Clover, although sweet and fairly well matured, were not as bulky as usual. Consequently yields of ensilage and meadow hay were not as heavy as other years, but some very fine quality fodders were conserved. The summer rains were below average, but ample paddock feed was available to stock until the break in the 1935 season occurred in mid-March.

The following table shows the monthly rainfall of recent years, compared with the average for the past 29 seasons:—

IMPROVEMENT OF NATURAL PASTURES WITHOUT CULTIVATION.

The work of top dressing natural pastures with phosphatic fertilisers and lime, that was commenced in 1919, is being continued on 13 plots of 3½ acres to 5 acres each in area. Grazing records have been kept since 1921, and for the past six seasons the plots have been continuously grazed in rotation by four flocks, constituted according to the estimated carrying capacity, and a separate flock has been used for each type of fertilised pasture. For five seasons Waite Institute wethers were used in conjunction with Kybybolite Comeback ewes in these flocks, but the wethers were removed at the end of 1933, and for this season additional Comeback ewe hoggets were utilised with the original (1928 drop) ewes in the flocks. This year A flock, consisting of 13 ewes, grazed on 13½ acres of unmanured land; B flock, of 44 ewes, grazed on the 14 acres of land improved with Superphosphate; C flock, of 60 ewes, grazed on the 17 acres of land improved with Lime and Superphosphate; and D flock, of 21 ewes, grazed on the 10½ acres of land improved with Rock Phosphate fertiliser. Another small flock has been used on all fertilised plots as required to utilise excess feed. Monthly weighings of ewes have been taken, so that a definite record of their development on this type of pasture is available.

The botanical analysis of these pastures was continued, and once per month throughout the growing period percentage estimations were made by taking six indiscriminate quadrat readings over each plot.

The following table shows the fertiliser applied, with date and rate of applications, whilst Table 3 shows the grazing results secured since 1921:—

TABLE 2.—*Fertilising of Natural Grazing Test, Kybybolite,* 1919-35.

Plot.	Total Fertiliser per Acre.	Date and Rate of Application.
6	No manure (check plot)	—
12	No manure (check plot)	—
1	1 ton Aluminium Phosphate Rock (412lbs. Phos. acid)	1919, one application.
4	11cwts. Calcium Phosphate Rock (232lbs. Phos. acid)	1919, one application.
	6cwts. Calcium Phosphate Rock (127lbs. Phos. acid)	1920-25, 1cwt. per annum.
	4½cwts. 82% Calcium Phosphate Rock (189lbs. Phos. acid)	1926-34, ½cwt. per annum.
5	1 ton Calcium Phosphate Rock (422lbs. Phos. acid)	1919, one application.
	10cwts. Calcium Phosphate Rock (420lbs. Phos. acid)	1929, one application.
11	6cwts. Ephos. Phosphate (188lbs. Phos. acid)	1924, one application.
2	11cwts. Aluminium Phos. Rock (227lbs. Phos. acid)	1919, one application.
	6cwts. Aluminium Phos. Rock (124lbs. Phos. acid)	1920-25, 1cwt. per annum.
	459lbs. 45% Superphosphate (94lbs. Phos acid)	1926-34, 51lbs. per annum.
7	990lbs. 45% Superphosphate (203lbs. Phos. acid)	1924-34, 90lbs. per annum.
8	1,620lbs. 45% Superphosphate (334lbs. Phos. acid)	1926-34, 180lbs. per annum.
3	1 ton Lime (Calcium carbonate)	1919, one application.
	1 ton Lime (Calcium carbonate)	1929, one application.
	1,770lbs. 36% Superphosphate (296lbs. Phos. acid)	1919-34, 1cwt. per annum.
10	1 ton Lime (Calcium Carbonate)	1924, one application.
	1,210lbs. 45% Superphosphate (249lbs. Phos. acid)	1924-34, 1cwt. per annum.
9	1 ton Gypsum (Calcium sulphate)	1926, one application
	986lbs. 45% Superphosphate (203lbs. Phos. acid)	1926-34, 1cwt. per annum.
13	1 ton crushed Limestone (Calcium carbonate)	1926, one application.
	986lbs. 45% Superphosphate (203lbs. Phos. acid)	1926-34, 1cwt. per annum.

										0·25			

The results show much higher returns than usual, and indicate that the season was very suitable for this type of pasture. No excess moisture being present in the winter allowed the plants to maintain healthy growth throughout, resulting in exceptionally high grazing from the well-fertilised plots. The average return from all fertilised plots in the series has been 3.79 sheep per acre for the season, which is the highest return so far received and is 1¼ sheep per acre above the average secured for the past 14 seasons.

Six individual plots yielded their best return since commencement. No 8, fertilised annually with 180lbs. 45 per cent. superphosphate, carried 5.72 sheep per acre, which is more than 1 sheep greater than any area of this type of pasture in previous seasons. This is the ninth season in which the superphosphate has been applied, and it carried a particularly healthy and vigorous pasture throughout the season. For the immediate past five seasons this plot has averaged over 4¼ sheep per acre per annum, illustrating clearly the advantage of maintaining the top dressing with superphosphate, and the futility of ceasing to top dress after the third or fourth application. Plot No. 13, top dressed with crushed limestone in 1926 and 1cwt. 45 per cent. superphosphate annually, also carried over 5 sheep (5.14) per acre for the season, an increase of 1¼ sheep on the previous season. Plot No. 7, dressed with 90lbs. 45 per cent. superphosphate annually, was next in order of productivity with 4.81 sheep per acre, and exceeded its previous highest return by 1 sheep. For the last five seasons this plot has averaged 3.80 sheep per acre, just ½ sheep less than No. 8 with the heavier application. Plot No. 9, dressed with gypsum and superphosphate, with 4.71 sheep per acre, also exceeded its previous best year by 1 sheep. Plot No. 2, dressed with 51lbs. superphosphate, with 3.76 sheep per acre, yielded ¼ sheep better than in 1933-34, whilst Plot No. 11, dressed with Ephos phosphate in 1924, yielded 2.81 sheep, which was a little better than its previous best in 1932-33. Plot No. 3 dressed with lime and superphosphate also carried 4.42 sheep per acre for the season, only slightly less than it did the previous year. This plot has averaged 4 sheep per acre for the past five seasons, a little greater yield than Plot No. 7, which has received the same annual application of superphosphate, but without the lime.

For this season the three plots dressed with lime and superphosphate have averaged 4.38 sheep per acre, and the three plots dressed only with superphosphate have averaged 4.76 sheep, showing 0.38 sheep per acre in favour of superphosphate without the lime, whilst the two plots, that have received continued applications of rock phosphate carried 2.41 sheep, quite 2 sheep per acre less.

The same plots (averaged over the immediate past nine seasons) have carried 3.25, 3, and 2.13 sheep per acre per annum respectively, showing an increase of 0.25 (8 per cent.) sheep for lime and superphosphate over superphosphate only; 1.12 (52 per cent.) sheep for lime and superphosphate over rock phosphate; and 0.87 (41 per cent.) sheep for superphosphate over rock phosphate.

Compared with the check plots (no manure) the same three series of plots have shown increases of 2.36 (265 per cent.), 2.11 (237 per cent.), and 1.24 (139 per cent.) sheep per acre per annum for the nine seasons.

It is to be noted that the plots dressed only with superphosphate have become quite as productive during recent years as those dressed with lime and superphosphate, and both series have advanced considerably in production. Rock phosphate dressed plots, however, have not made much improvement, and maintain a production much less than the former two series.

In the following table the average of all plots for the past nine seasons have been grouped together according to the various forms of fertiliser, and shows an interesting comparison of returns and value:-

NATURAL PASTURE.

TABLE 4.—*Comparative Summary of Nine Years Grazing on Topdressed Natural Pasture.*

Fertilisers Applied.	Area.	Sheep per Acre.	Increase over No-Manure.	Increase over Super-phosphate.	Increase over Rock Phosphate	Annual Cost of Fertiliser per Acre.	Annual Cost of Fertiliser per Sheep.	Profit per Acre per Annum, Sheep. at 15s.
	Acres.		%	%	%	*s d.*	*s. d.*	*s. d.*
Lime and Superphosphate (W.S.P.)	8½	3·30	271	10	55	9 6	3 11	26 8
Crushed Limestone and Superphosphate (W.S.P.)..	5	3·16	255	5·3	48	8 3	3 8	25 9
Superphosphate (W.S.P.)	10½	3·00	237	—	41	5 5	2 7	26 3

Ephos Phosphate (Cit. and Acid Sol. Phos.)	5	2·19	146	—	2·8	4 0	3 1	15 6
Crushed Rock Phosphate (A.S.P.)	7	2·13	139	—	—	3 11	3 2	14 8
No-Manure (Check Plots)	8½	0·89	—	—	—	—	—	—

This table shows that when sheep are valued at 15s. each per annum, the profit obtained due to fertiliser has been approximately the same from the use of Superphosphate only, and from Lime and Superphosphate combined. The cost of Superphosphate dressings has been 5s. 5d. per acre, or 2s. 7d. per sheep, whilst that of Superphosphate and Lime combined has been 9s. 6d. per acre, or 3s. 11d. per sheep. The extra sheep carried on the Lime and Superphosphate plots has only covered costs.

Crushed Limestone and Superphosphate combined show a profit of 25s. 9d. per acre per annum, only 11d. less than Burnt Lime and Superphosphate, whilst Gypsum and Superphosphate combined and Ephos Phosphate have returned much lower profits, with 18s. 10d. and 15s. 6d. per acre respectively.

Rock Phosphate, with its low annual cost of 3s. 11d. per acre, has returned 14s. 8d. per acre profit.

With reference to the type and variety of plants growing on these series of plots, the monthly estimations taken throughout the growing period of 1934 have been averaged and are shown in the following table with those of 1933.

TABLE 5.—*Botanical Analyses of Natural Pasture Plots, Kybybolite,* 1933 *and* 1934.

Clovers	16·23	16·00	19·75	22·12	10·07	24·12	16·81	21·65	0·18	0·70
Erodium	0·96	0·60	1·78	0·80	7·04	2·20	3·26	1·38	trace	trace
Thistles	0·08	—	0·68	0·30	2·32	0·50	1·03	0·32	0·35	0·10
Capeweed	0·12	—	0·65	0·33	1·49	0·65	0·81	0·40	0·12	—
Miscellaneous	12·39	6·30	6·64	5·59	7·95	7·55	7·82	7·61	29·76	27·50
Bare Space	4·76	11·40	1·91	8·61	3·12	7·10	2·88	8·56	24·72	28·30

Factors of note from this table are the percentage of grass to clover under the various fertilisings, the almost complete absence of clover growths on the check plots, and the great reduction of miscellaneous plants and bare space on the fertilised plots.

In 1934 the proportion of clover was greater and that of grass was less than the previous season, particularly on the Lime and Superphosphate dressed plots. The pasture on the Rock Phosphate dressed plots has scarcely varied. The percentage of clover on the Limed plots was 24 per cent. this year and only 10 per cent. in 1933, whilst on the plots dressed only with Superphosphate its percentage was 22 per cent. and 20 per cent. respectively.

The variation of grass percentage, except that it has been reversed, has been somewhat similar. On the Limed plots it was 68 per cent. in 1933 and 58 per cent. in 1934, whilst on the Superphosphate plots it was 68½ per cent. in 1933 and 62 per cent. in 1934.

Although the Limed plots still produced the most Erodium, Thistle, and Cape Weed; the proportion of these plants in 1934 was considerably less than in 1933. For the two seasons the amount of Erodium has been 4.6 per cent. on the Limed plots as against 1.29 per cent. on the Superphosphate plots, the amount of Thistle has been 1.4 per cent. and 0.49 per cent., and that of Cape Weed 1.07 per cent. and 0.49 per cent. respectively. The amount of bare space on all plots was greater in 1934, and was due to the unusually dry periods of May and June, which caused the plots to be grazed back very much harder at that period.

Time does not permit to analyse fully the various grasses that grow on the plots, but each autumn counts and measurements were made of the *Danthonia* (Native Wallaby Grass) plants by reading six indiscriminate square metres on each plot. On averaging the growths of the last three autumns, the number and size of plants per square metre on the various fertilisings were as follows:—

	Number of Plants.	Diameter in Inches at Ground Level
Check Plots (no manure)	112	0·75
Rock Phosphate plots....................................	58	1·58
Superphosphate plots......................................	39	1·47
Lime and Superphosphate plots	24	1·39

This result shows that the fertilising has apparently depressed the number of permanent native grass roots, but has increased the vigour of those that have survived.

In records of the development and production of sheep flocks, used for grazing these natural pasture plots, Table 6 shows the average live weight of Comeback ewes, the average weight of wool, percentage of lambs marked, average weight of lambs at weaning, and the sheep carried per acre for each of the four flocks during the past five seasons.

All of the ewes in these four flocks are of similar age and breeding (1928 spring drop), and were selected as even in type and development in May, 1929. Since then they have been kept wholly on the one class of pasture. Except for a few weeks in the autumn of each season, when the 86 ewes were mated together as one flock with Merino rams, they have been pastured on the respective plots, fertilised as shown in Table 6. They have received no hand feeding, nor provided with any licks.

The average live weights of ewes quoted are those taken about the close of March each season, a time when their weights were lowest. During each season of growing pasture, the ewes increased in weight and during each late summer and autumn they decreased in weight.

The average maximum weights attained by the four flocks for the five seasons, which occurred in the late spring, were:—

	Lbs.
Flock A	109.9
Flock B	115.7
Flock C	120.6
Flock D	105.9

Unimproved Pasture at Kybybolite. Carrying capacity, 0.69 sheep per acre per annum.

When these are compared with the autumn weights given in Table 6, it is seen that the average difference between the maximum and minimum weights of each flock has been: —

	Lbs.	Variation Per cent.
Flock A	17.3	18.7
Flock B	21.7	23.1
Flock C	24.0	24.8
Flock D	18.0	20.5

Hence the ewes pasturing on the natural pasture, that has been fertilised with Superphosphate only, and with Lime and Superphosphate combined, have shown that they reached much higher weights during the flush parts of the seasons, but also lost more pounds in weight during the dry-grazing periods.

At all times, however, they maintained greater weights than those on unfertilised pasture, despite the fact that there were less dry ewes in these flocks than in A flock. Those on pasture fertilised with both Lime and Superphosphate have maintained slightly better weights than those on pasture fertilised only with Superphosphate, especially during the last three seasons.

As regards the wool production per head, the figures in Table 6 show that there has been no material difference between the flocks. There has been a difference of only 4ozs. per head between the highest and lowest average—8lbs. 4ozs. from Flock C; 8lbs. 5ozs. from Flock A; 8lbs. 6ozs. from Flock B; and 8lbs. 8ozs. from Flock D.

The lambing percentages, however, show a distinct difference, those on the Lime and Superphosphate pasture yielding an average of 87.6 per cent. over the five seasons, as against only 64.6 per cent. from the flock on unmanured pasture, the former producing the highest percentage of the four flocks in three seasons, 1930, 1933, and 1934, whilst D Flock on Rock Phosphate fertilised pasture gave the highest percentage in the other two seasons, 1931 and 1932. Both B and D Flocks with 79 per cent. and 80 per cent. averages, were considerably better breeders than A Flock. These figures are the actual percentages of lambs marked. For three of the five seasons a record of the births, and the deaths that occurred between birth and marking has been kept, and although these deaths have been 100 per cent. greater in A Flock than in the others there is still a high margin between the flocks. This experiment, therefore, shows that ewes grazed on natural pasture fertilised with Lime and Phosphate are more fertile by 7 per cent to 10 per cent. than those grazed on the same pasture manured only with Phosphates, and by 18 per cent. than those grazed on the same pasture not manured at all. The high percentages of 94 and 103 secured from the former flock for the last two seasons indicate that their health, vigour, and fertility have been very well maintained into the sixth year of life of the ewes.

The weights of lambs at weaning show that those from the A Flock have been the heavier lambs. This is due entirely to the different summer feed available during December on the unfertilised pasture. These fertilised pastures at this time of the year contain a large proportion of dry annual grasses, such as Barley and Silver Grasses, with their objectionable seed heads, which have proved detrimental to the lambs. It is definitely not due to the strength of the lambs, as the lambs in B and C Flocks have invariably been stronger from birth, and for the five seasons averaged 2lbs. greater in weight during October months than those on the unmanured pasture.

It must be noted that to supplement the amount of unfertilised feed, Plot No. 9 in unmanured clover land series necessarily had to be used by Flock A, which accounts for the carrying capacity of plots grazed showing at 1.01 sheep per annum, which is higher than unfertilised virgin land, and should, if anything, give the flock an advantage.

Regarding losses of sheep that have occurred amongst these flocks, eight ewes of the original 87 have died, two in Flock A, three in Flock B, two in Flock D, and one in Flock C. One died as a hogget in Flock B in 1929, one died at four years of age in the same flock in 1932, two died at five years of age in Flock D in 1933, and four died at six years of age in 1934, including two in Flock A and one in each of Flocks B and C. The annual percentage loss of ewes over the six seasons for each flock has therefore been as follows:—

		Per Cent.
Flock A (9 ewes)	2 deaths	3.70
Flock B (27 ewes)	3 deaths	1.85
Flock C (36 ewes)	1 death	0.46
Flock D (15 ewes)	2 deaths	2.22
All flocks (87 ewes)	8 deaths	1.53 per annum

This loss of 1½ per cent. per annum is small and as most of the deaths have occurred at five and six years of age the loss can only be looked upon as a normal one in flocks.

Referring to the losses of lambs that have occurred between marking and weaning for the five lambing seasons, these have been as follows:—

Flock A has lost 3 lambs from 29 marked, *i.e.*, 10.34 per cent.
Flock B has lost 5 lambs from 102 marked, *i.e.*, 4.90 per cent.
Flock C has lost 8 lambs from 157 marked, *i.e.*, 5.10 per cent.
Flock D has lost 0 lambs from 58 marked, *i.e.*, nil

Total .. .. 16 lambs from 346 marked, *i.e.*, 4.62 per cent.

Subterranean Clover and Wimmera Rye Grass Pasture Plots at Kybybolite.

During the immediate past three seasons, a record has been kept of the losses of lambs at birth and between birth and marking. The numbers for each flock for the three seasons have been:—

Flock A	4 lambs, *i.e.*,	16.0 per cent.
Flock B	4 lambs, *i.e.*,	5.80 per cent.
Flock C	9 lambs, *i.e.*,	8.18 per cent.
Flock D	3 lambs, *i.e.*,	7.89 per cent.
Total	20 lambs, *i.e.*,	8.26 per cent.

These lamb losses have been comparatively small, but it is worthy of note that on the manured plots they have been only half proportionately to those on unmanured pasture, where 26 per cent. of births have died by weaning time. This must undoubtedly be regarded as a definite illustration of the better health of stock obtained by manuring the feed with Phosphates and Lime.

Summarily, the results of top dressing this natural pasture show a large increase in wool production per acre. The averages for the past five seasons show that the unmanured land has returned 8.39lbs. of wool per acre per annum; the same virgin land fertilised with Superphosphate only has returned 30.32lbs. of wool (261 per cent. increase); fertilised with Lime and Superphosphate it has returned 30.36lbs. (262 per cent. increase); and fertilised with Rock Phosphates it has returned 18.19lbs. of wool (117 per cent. increase) per acre per annum.

The ewes used in this experiment are now 6½ years of age, and five seasons' results of their production have been reported, and it is now proposed to discontinue further recording of the behaviour of sheep on the various fertilisings of natural pasture.

SOWN PASTURES—SUBTERRANEAN CLOVER AND WIMMERA RYE GRASS.

Thirteen of the 15 plots of this pasture mixture established during 1924 were maintained, and fully grazed during the season. They were again grazed in rotation using 252 Comeback ewes, including 62 (1929 drop), 49 (1930 drop), 46 (1931 drop), 32 (1932 drop), and 63 (1933 drop). The 52 aged half-breds previously used in these flocks were culled this season, and were replaced by 63 Comeback hoggets, so that the flocks now consist entirely of ewes bred and reared on these plots, and have received no supplementay feed or licks. They were proportionately divided into four flocks, and grazing has been continuous on the plots for the whole season.

Table 7 shows the fertiliser given to various plots with the rate and time of application, and Table 8 shows the grazing results for the past 10 years:—

These results show that Subterranean Clover pasture, that has been receiving continued applications of fertiliser, is increasing its carrying capacity annually. This season the average number of sheep carried over all plots has been 4.02 per acre, just a little less than the previous season, but considerably more than was carried during the first few seasons of development. The average carried on all plots for the 10 years has been 3.45 sheep, whilst for the last seven seasons it has been 3.63 sheep, and for the last three years 3.95 sheep per acre have been carried. These results are quite 1 sheep per acre better than the average secured from improved natural pasture previously discussed.

Considering the individual plots, No. 5 dressed with 180lbs. 45 per cent. superphosphate annually has been the most productive, again exceeding 6 sheep per acre (6.23 this season and 6.11 last season). This plot has maintained a very healthy and vigorous pasture throughout the whole of the growing period, and the increasing capabilities of the plot are significant in showing that the limit of production from the use of superphosphate and Subterranean clover in these soils is not yet attained. Plot No. 7, fertilised with lime and superphosphate, in carrying 5.97 sheep per acre for the season, again maintained a very vigorous pasture, and continues to show a steady rise in stock carrying. With this plot there has been a steady annual rise since 1927 from 3¼ sheep to 6 sheep per acre. Three other plots exceeded 5 sheep per acre, namely No. 3, fertilised with gypsum and superphosphate, carried 5.44 sheep; No. 15, dressed with 1cwt. superphosphate annually carried 5.32 sheep; and No. 4, dressed with 90lbs. superphosphate annually carried 5.22 sheep. It is significant that the plots receiving the least phosphate fertiliser carried the lowest number of stock, and the two plots (Nos. 9 and 12) that have received no phosphate fertiliser at all carried less stock this season than they have during any season of the last ten. This clearly shows the ability of well-fertilised pasture to withstand dry winter periods such as we experienced last May and June.

For the 10 years Plot No. 7 (lime and superphosphate) has been the most productive with 4.67 sheep per acre per annum, and No. 5 (heaviest dressed superphosphate plot) is second in productivity with 4.56 sheep, closely followed by No. 4 (90lbs. superphosphate) with 4.37 sheep. Plots No. 15 (1cwt. superphosphate), No. 3 (gypsum and superphosphate), and No. 8 (basic slag) have also exceeded 4 sheep per acre per annum.

For the immediate past seven years, however, Plot No. 5 (180lbs. superphosphate) has yielded greatest return with 5.32 sheep per acre per annum, closely followed by No. 7 (lime and superphosphate) with 5.24 sheep. For the same period, No. 4 (90lbs. superphosphate) and No. 3 (gypsum and superphosphate) have carried 4.83 sheep; No. 15 (1cwt. superphosphate), 4.38; and No. 8 (basic slag), 4.15 sheep per annum.

As a comparison of the quantity of superphosphate test Table 9 shows the results from 180lbs., 90lbs., and 45lbs. dressings compared with no manure:—

TABLE 9.—*Superphosphate Quantity Test on Subterranean Clover and Wimmera Rye Grass, Kybybolite,* 1928-35.

Plot.	Sheep Carried per Acre.	Increase over no Manure.	Annual Cost of Fertiliser per Acre.	Annual Cost of Fertiliser per Sheep.	Value of increased Grazing at 15s. per Sheep.	Profit per Acre per Annum due to Fertiliser.
	%	%	*s. d.*	*s. d.*	*s. d*	*s. d.*
Super—						
No. 5 180lbs. (37lbs. phos. acid) ...	5 32	4·25	8 7	2 0	63 9	55 2
No. 4 90lbs. (18½lbs. phos. acid) ...	4·83	3 76	4 6	1 2	56 5	51 11
No. 6 45lbs. (9¼lbs. phos. acid)	3·27	2·20	2 6	1 2	33 0	30 6
No. 9 No manure	1·07	—	—	—	—	—

These results are the average annual returns over seven consecutive seasons, and indicate the values to be obtained from the use of Superphosphate on a sown pasture of Subterranean Clover and Wimmera Rye Grass, combined with systematic rotational grazing. For this grazing the fertilised plots have been fed off monthly in rotation with approximately 16 sheep per acre, whilst the unfertilised plot was grazed monthly with approximately three sheep per acre. The table shows that when sheep are valued at 15s. each per annum the increased return per acre per annum due to the fertiliser has been 55s. 2d. from the 180lbs. dressing, 51s. 11d. from the 90lbs. dressing, and only 30s. 6d. from the 45lbs. application. Hence it appears that the 90lbs. annual application is very suitable and economical under local conditions.

Referring further to Table 8 the averages for 10 seasons show that lime and superphosphate are the most productive of the fertilisers tried. The two combined have given the greatest yield, whilst superphosphate on its own has yielded almost as well in quantity of feed. Lime has an advantage, however, in producing quicker early feed, and more during the colder months of the year.

Table 10 shows the comparison of Lime, Gypsum and Basic Slag with that of Superphosphate only.

TABLE 10.—*Lime, Gypsum, and Basic Slag Test on Subterranean Clover and Wimmera Rye Grass, Kybybolite,* 1928-35.

Plot.	Fertiliser.	Sheep carried per Acre.	Increase over no Manure.	Cost of Fertiliser per Acre.	Cost of Fertiliser per Sheep.	Value of increased grazing at 15s. per Sheep.	Profit per acre per annum due to Fertiliser.
				s. d.	*s. d.*	*s. d.*	*s. d.*
7	Lime & Super. .	5·24	4·17	10 6	2 6	62 7	52 1
3	Gypsum & Super.	4·83	3·76	10 6	2 10	56 5	45 11
8	BasicSlag	4·15	3·08	8 8	2 11	46 2	37 6
4	Superphosphate	4·83	3·76	4 6	1 2	56 5	51 11
9	No Manure	1·07	—	—	—	—	—

These results show that although Lime and Superphosphate together provide more feed, the increase apparently due to lime, just covers cost of lime, there being practically no greater profit than that received from Superphosphate used on its own. The only possible advantages at present shown from the use of Lime are the quicker early autumn and winter growths, and a slightly higher proportion of grass to clover in the pasture.

The result from Gypsum, so far, shows no greater return in quantity of feed than from Superphosphate only. Also that received from Basic Slag or Ephos Phosphate (citrate soluble phosphatic fertilisers) has not been as great as the quantity of grazing provided by Superphosphate, and shows only a profit of 37s. 6d. per acre, compared with 51s. 11d. from Superphosphate, and 52s. 1d. from Lime and Superphosphate.

TABLE 11.—*Acid Soluble Phosphate Fertiliser Test on Subterranean Clover and Wimmera Rye Grass, Kybybolite,* 1928-35.

Plot.	Fertiliser. (Island Phosphate.)	Sheep. carried per Acre.	Increase over no Manure.	Fertiliser Applied every Five Years.			
				Cost of Fertiliser per Acre.	Cost of Fertiliser per Sheep.	Value of increased grazing at 15s. per Sheep.	Profit per Acre per annum due to Fertiliser.
				s. d.	*s. d.*	*s. d.*	*s. d.*
10	494lbs. (37lbs. Ph. Ac. p. a.).	3 16	2·09	4 2	2 0	31 4	27 2
11	247lbs. (18½lbs. Ph. Ac. p. a.)	3·48	2·41	2 1	0 10	36 2	34 1
14	123lbs. (9¼lbs. Ph. Ac. p. a.)	2 67	1·60	1 1	0 8	24 0	22 11
9	No Manure	1 07	—	—	—	—	—

Table 11 compares the results secured from applications of acid soluble phosphatic fertiliser, applied every five years, at rates equivalent in phosphoric acid content to annual applications of 180lbs., 90lbs., and 45lbs. of 45 per cent. Superphosphate. These results so far show advantage to the medium application of 247lbs. 82 per cent. Island Phosphate per acre every five years, but the returns show only 61 per cent. of the profit secured from similar quantities of water soluble phosphate, as given in Table 9.

TABLE 12.—*Potash Fertiliser Test on Subterranean Clover and Wimmera Rye Grass, Kybybolite,* 1928-35.

Plot.	Fertiliser.	Sheep carried per Acre.	Increase over no Manure.	Cost of Fertiliser per Acre.	Cost of Fertiliser per Sheep.	Value of increased grazing at 15s. per Sheep.	Profit per per annum due to Fertiliser.
				s. d.	*s. d.*	*s. d.*	*s. d.*
13	Island Phosphate and Potash ..	3·86	2·79	9 8	3 6	41 10	32 2
10	Island Phosphate	3·16	2·09	4 2	2 0	31 4	27 2
12	Potash	2·14	1·07	5 6	5 2	16 1	10 7
9	No Manure	1·07	—	—	—	—	—

This table compares the results secured from potash fertiliser on its own, and in conjunction with acid soluble phosphatic fertiliser, and indicates a profit of 10s. 7d. over no manure, and 5s. over acid soluble phosphate. These differences are small, and show no great need for this type of fertiliser at the present stage of development.

Natural virgin unimproved pasture at Kybybolite. Carrying capacity, 0.69 sheep per acre per annum.

The values in these four tables have been calculated from the following manure prices, plus cost of application, and the sheep value used has been 15s. per annum.

	Per Ton. £	s.	d.
Superphosphate	5	0	0
Island Phosphate	4	10	0
Basic Slag	7	0	0
Lime	2	0	0
Gypsum	2	0	0
Potash	15	0	0

With reference to the variety of growths now appearing on these plots, monthly estimations have been taken throughout the growing periods of the last two seasons by reading six indiscriminate quadrat sections on each plot. Table 13 shows the average per centage of annual grasses, Subterranean Clover, Cape Weed, Thistles, &c., on the various series of fertilised plots taken during the seven months of growing pasture of both seasons.

In making the estimation of pasture plants no attempt has been made to separate the various species of grasses. The grasses consisted wholly of annual types, principally Barley Grass, with some Wimmera Rye, Silver, and Sterile Brome. Wimmera Rye was not much in evidence, providing not more than 5 per cent. of the pasture on the best plots. An interesting factor shown by the above table is the variation in amount of grass to clover with the different manurings. The percentage of grass is highest on the Lime and Superphosphate plot with 56.55 per cent. average for the two seasons, and next highest on Gypsum and Superphosphate plot, 52.77 per cent. The same pasture fertilised with Superphosphate only has yielded 46.03 per cent. of grass. When fertilised with acid soluble phosphate the percentage of grass shows at 32.6 per cent., fertilised with potash only 29.6 per cent., fertilised with Basic Slag 36.86 per cent., whilst on unmanured pasture the percentage of grass has only been 12.32.

The percentage of clover has been reversed, being only 33.02 per cent. of the pasture on the Lime and Superphosphate plot, and 75.2 per cent. of the pasture on the unfertilised plot. It is necessary to state that these plots were established on old cultivated land, which contained a certain residue of phosphate from crop fertilisings, and which has enabled the Subterranean Clover to persist on the check plot throughout the 11-year period. However, although it has made cover over the plot to the extent of 75 per cent., the clover has made very little growth, and provided very poor feed.

Thistles have appeared on most fertilised plots in comparatively small numbers, except on the Lime and Superphosphate plot, which has contained on the average over 5 per cent. thistles, principally of the Scotch and Slender varieties.

Cape Weed was less consistent on the plots, and considerably less was present in 1934 than in 1933. The plot dressed with Basic Slag contained 4.83 per cent. for the two seasons, but none of the others carried any appreciable quantity.

Miscellaneous plants were also comparatively less in 1934, and were most plentiful on the Lime and Superphosphate, and potash dressed plots. Naturally the proportion of bare space was greater in 1934, due to the dry, early winter and consequent heavy winter grazing, but nevertheless the unmanured plot had very much the greatest proportion with 17.5 per cent. For the two seasons, the proportion on this plot has been 11 per cent. bare space, whilst on the potash dressed plot it has been 6.17 per cent., and the average of all phosphate dressed plots has been 2.76 per cent. The least bare ground has been on the limed plot with only 1.5 per cent.

TABLE 14.—*Botanical Analysis of Clover Pasture Fertilised with Various Quantities of Superphosphate, Kybybolite,* 1933 *and* 1934.

Species.	Plot 5 (180lbs.)		Plot 4 (90lbs.)		Plot 6 (45lbs.)	
	1933.	1934.	1933.	1934.	1933.	1934.
	%	%	%	%	%	%
Grasses	47·2	52·5	44 9	46·9	37·1	42·2
Clover	50 2	41·5	52·9	48·1	62·2	52·2
Thistles	0·1	1·4	0·1	0·2	0·1	Trace
Cape Weed	Trace	Trace	0·2	Trace	—	Trace
Miscellaneous	2·5	0·3	0·9	0·1	0·2	0·1
Bare Space	—	4·3	1·0	4·7	0·4	5·5

Table 14 shows the percentage estimated botanical composition of the pastures growing on the three plots dressed with varying amounts of 45 per cent. Superphosphate, and are most interesting in that they clearly show that the proportion of grass to clover is highest on the plot receiving the most Superphosphate. For both seasons a similar difference has been present, and the average for the annual dressing of 180lbs. shows approximately 50 per cent. grass and 46 per cent. clover, that for the 90lbs. dressing shows 46 per cent. grass and 50 per cent. clover, whilst that for the small dressing of 45lbs. shows grass only 40 per cent. and clover 57 per cent.

(*To be continued.*)

AGRICULTURE IN THE TEMPERATE AND SUB-TROPICAL CLIMATES OF THE SOUTH.

[A Report by the Deputy Director of Agriculture (W. J. Spafford) to His Excellency Sir Winston Dugan, K.C.M.G., C.B., D.S.O., Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia. Mr. Spafford took a brief tour of portions of the principal agricultural countries in the same climatic zones as the settled portions of Australia, in fulfilment of the appointment as Honorary Commissioner, conferred upon him by His Excellency, to inquire into and report upon the Production and Preparation for Marketing of Agricultural Products, including Crops and Livestock in South America, South Africa, and New Zealand.]*

(*Continued from page* 661.)

CHILE.

A peculiar-shaped country located along the western side of South America, between the Andes and the Pacific Ocean, Chile includes considerable areas of country which are rainless or almost so. Furthermore, much of the country is of volcanic origin, and although a serious disturbance has not occurred since the bad earthquake of 1906, small shocks are frequent, and the danger of big upheavals is ever-present. Despite these handicaps the Republic is a fairly important agricultural country, and will become increasingly so as time goes on, and, as the climatic conditions are quite similar to those of southern Australia, when Chile makes agricultural progress she must do it along similar lines to those followed by Australia.

THE COUNTRY OF CHILE.

In shape Chile is a very long, narrow strip of country bounded by the Pacific Ocean on the west and the mighty Andes on the east, and in all probability is the narrowest country in the world in proportion to its length. Although Chile has a coastline of 2,800 miles, the extreme length of the country, in a straight line, is 2,661 miles, with the width of the mainland varying from 46 to 228 miles, and of an average width of about 100 miles. The northern boundary of Chile is the southern boundary of Peru, and the northern extremity is at 17° 21′ south latitude, from where the country extends almost due south to Cape Horn, located at 55° 58′ 40″ south latitude. The countries on the eastern boundary are Bolivia for a short distance in the north and Argentina for the remainder of the way. From the north, down to somewhere near the forty-second parallel, the coastline is comparatively regular, but below this point is very broken and a great number of islands are located close to the shore-line. The total area of the country is variously computed, but the official figure, which includes all islands, is 307,774 square miles, or 196,975,360 acres.

As is to be expected in a country with one of its boundaries the ridge of such a high range of mountains as is the Andes, and that boundary only averaging about 100 miles from the coastline, Chile is a mountainous country, and only a relatively small proportion of its area is suitable for arable agriculture. It is not only the mountainous nature of the country which renders so much of it unsuitable for cultivation, but a very large proportion of the northern end is

---

***Tour made in the company of Col. C. P. Butler ("Yattalunga," of the *Advertiser*).**

rainless, or almost so. From an agricultural point of view the country is generally divided into the deserts of the north, the arable lands of the central regions, and the forest areas of the south. It is in the northern desert area where the huge deposits of nitrate of soda are located, and besides containing this substance the zone is rich in metals of several kinds. A little agriculture under irrigation is practised in the north of Chile, but most of the streams originating in the Andes are very short, the water sinking into the bare sun-baked lands of the desert. Most of the crop-growing and stock-raising activities of Chile are carried out in the central zone, and in the south nearly all of the lands are still under forest, except near the extreme end of the country, where large numbers of sheep are maintained.

[From *Bulletin of the Pan American Union.*

A Livestock Farm, well up in the Mountains, near the Town of Los Andes. Although so much of Chile is high above sea level, there are rich tablelands and very fertile valleys in the hills. The illustration shows a luxuriant pasture on a plain, backed by the snow-capped Andes, and protected by Poplar trees, which are commonly grown as breakwinds in the country.

The utilisation of the agricultural lands of the three main regions of Chile is set out below:—

*Utilisation of the Agricultural Lands of Chile.**

Utilisation.	North Chile.	Central Chile.	South Chile.	Whole Country.
	Acres.	Acres.	Acres.	Acres.
Being farmed	52,611	8,265,114	22,971	8,340,696

* Sinopsis Geográfico-Estadística de la República de Chile.

THE RAINFALL OF CHILE.

One end of this long narrow country of Chile is almost rainless whilst towards the southern end more than 80ins. of rain are received annually on the average. The desert area does not extend right across the northern end of the country, but runs along the coast from the boundary of Peru to a little below Antofagasta, then leaves the coast and continues down the middle of the country for some 150 miles or so. This dry zone is about half of the width of the country throughout the length of the zone. Between the desert area and the ridge of the Andes the average annual rainfall gradually gets greater, and in going south heavier and heavier rainfalls are recorded, until the southern extremity of the country is approached where considerably reduced amounts are received. The approximate areas of country receiving different amounts of rain are somewhat as follows:—

Below 0.4ins.	about 39,000 square miles.
Between 0.4 and 4ins. ..	about 66,000 "
" 4 and 10ins. ..	about 19,000 "
" 10 and 20ins. ..	about 10,000 "
" 20 and 40ins. ..	about 39,000 "
" 40 and 80ins. ..	about 39,000 "
Above 80ins.	about 96,000 "

Except in the zones receiving the very heaviest average annual rainfalls most of the rain is received in the winter, and the summer is dry, and in many places there are usually but four or five wet months in the year, and very little precipitation during the remainder of the year.

The next table sets out the average annual rainfall and the average annual maximum and minimum temperatures for 19 recording stations fairly evenly spaced down the length of Chile:—

CHILE, AN AGRICULTURAL COUNTRY.

In the past a lot of the wealth of Chile was derived from the wonderful deposits of nitrate of soda and from the metals from her mines, but of recent years so many countries have been collecting and storing nitrogen from the air that much of the value of these enormous nitrate deposits has gone, and she is now developing her agricultural resources as never before. The extreme length and narrowness of the country almost certainly increases the difficulties of political administration but it does not hamper agricultural operations or prospects in any way, and Chile is blessed with fairly considerable agricultural potentialities. Of the population of about 4,500,000 people something between 40 per cent. and 50 per cent. live in country districts and are directly dependent upon agriculture, but most rural practices are conducted in such a very primitive manner that the yields from crops and pastures are much lower than will be the case when improved methods are adopted. Much of the cultivation of crops grown in rows is still carried out by hand hoes; ploughing and cultivation is in many cases done with a bent stick shod with iron, or with a one-handled plough of primitive type; a pair of bullocks with yokes secured to the horns with green-hide thongs comprise the principal teams seen in Chile; cereals are cut with sickle, tramped out under the feet of horses and mules and winnowed in the wind; and other primitive methods are in vogue. On the other hand some of the larger agricultural holdings are conducted with the most modern methods, such as nurseries, vineyards, orchards, dairies, etc., and in some localities mixtures of primitive and modern systems are to be seen, and particularly in the cooler districts of the south, where sickles are still in use for the cutting of the crops, but power threshers, driven by the most modern of tractors or other engines, are used to thresh and clean the grain.

Carting Beer on Horseback in Chile.
Where the country is very hilly most articles are "packed" on horses or donkeys for transportation purposes, and the carter usually rides on the animal as well, no matter how heavy the load.

Although about three-fifths of the whole area of Chile is mountainous there are still over 70,000,000 acres of land suitable for agricultural pursuits, a very high proportion of the agricultural land is still covered with forest growth, enormous quantities of water from the melting snow of the Andes is available for irrigation purposes, and so the possibilities for extension of agricultural production are very great indeed. The principal agricultural area, known as the Vale of Chile, is over 600 miles long by about 60 miles wide, and as much of it is blessed with from 40 to 100ins. of average annual rainfall, possesses deep, rich volcanic soils, and has good natural drainage, enormous areas of first-class pastures will be developed some day, and water is so plentiful in the lower rainfall portions that a great extension in fruits and vines can be anticipated for the future.

The climate of Chile being in the main what is known as Mediterranean climate, water for irrigation being really plentiful, and considerable areas of fertile soils with good natural drainage being available, it appears certain that in the future this country will be a very important producer of wine, fruits, olive oil, nuts, dairy produce, and mutton (lambs), as well as produce fair quantities of cereals, legumes and maize.

At present the principal agricultural productions of Chile consist of wheat, oats, beans, barley, maize, vines, vegetables, pastures, and farm livestock, and quite a considerable proportion of the area sown to most crops is irrigated. The following tables give the area of the principal crops grown, the proportion irrigated of most of the crops, and the numbers of the various kinds of livestock maintained in the country:—

Area of Principal Crops and Proportion Irrigated—Chile, 1929-30.*

Crop.	Area Sown.		Percentage Irrigated.
	Total.	Irrigated.	
	Acres.	Acres.	%
Wheat	1,723,880	373,538	21·7
Oats	297,371	9,334	3·1
Barley	152,108	96,239	63·3
Rye	8,445	1,835	21·7
Canary seed	768	840	83·3
Maize (for grain)	93,733	64,252	68·5
Maize (for silo)	13,234	?	?
Beans	164,248	123,769	75·4

EXPORTS OF AGRICULTURAL PRODUCE.

Although the agricultural exports of Chile have not yet reached very considerable dimensions there are very few of the agricultural products suitable to the natural conditions which are not being exported to some extent, and now that agricultural production is being encouraged in the country some of the kinds will soon be very important indeed. At present the principal items being exported are wine, cereals (barley and oats), legumes (beans, peas, and lentils), onions (onions and garlic), melons (mainly sweet melon), apples, wool, meat (sheep), hides, and honey. The next table gives details of the principal agricultural exports, and the progress made since 1928:—

WINE IN CHILE.

The growth of vines and the manufacture of wine have been practised on an extensive scale in Chile ever since the original settlement of the country by the Spanish, and the natural conditions of much of the country are so suitable for wines, and the founders of the industry were so highly skilled, that Chile has been noted for a very long time as a producer of wines of extremely fine quality. Other than minerals (most metals, nitrate of soda, sulphur, &c.) the production of wine is the most important industry of Chile, producing as it does much wealth for the country, and employing a lot of labour. In 1934 the vineyards registered consisted of 34,594 holdings, and covered an area of 211,484 acres, and as most growers make their own wine considerable capital is invested in the industry, and the labour requirements are very great, for much of the cultivation work is done by hand hoes, and where teams are used they almost invariably consist of yokes of two bullocks only.

The production of wine fluctuates between 50,000,000galls. and 74,000,000galls. per year, and as the export of this article only reaches about 1,500,000galls. a year, the consumption of this beverage is fairly high in Chile.

Delivering Milk on Horseback in Valparaiso.

Besides doing so much of the heavy transport work on pack horses and pack donkeys, milk is delivered to consumers on horseback in the steeper towns of Chile, the distributor invariably riding between the milk cans.

The vineyards of Chile are located in the middle Provinces of the country, nearly all of them being within the boundaries of Santiago, Colchagua, Talca, Maule, Nuble, Concepción and Bío-Bío. In the northern of these Provinces the vines are irrigated, but in the south the rainfall is ample to promote full, luxuriant growth. About 38 per cent. of the total area of vineyards is irrigated, and as the soils have good natural drainage, and fresh water from the melting snow of the Andes is plentiful, water is liberally applied, even to the extent of irrigating the vines every 12 to 15 days throughout the period of October to April. This practice has been followed for a very long time, and in a really hot Mediterranean climate, still the texture of the soils and the quality of the water are such that there are no signs of a rise of excess of injurious salts.

The cultivation of most vineyards seen was really good, particularly in the larger ones, and as so much of the cultivation is done by hand hoes neither odd corners nor single weeds are missed, and the holdings have a neat and tidy appearance. In the irrigated areas the growth made by the vines is very regular, but farther south many of the vineyards are irregular and some quite poor.

Chile is in the fortunate position of being free from Phylloxera, and so retains the advantage of cheap establishment of vineyards, full regular growth, and long life of the vines, and a continuance of the special qualities of well-known old-established brands of wine.

About 70 per cent. of the wines are red and the remainder white, and the great majority of them are of low alcoholic content That their quality is good is generally recognised and the best of them are considered by experts to be among the highest-class wines of the world. Champagne of good quality is made in Chile, both by the traditionally-correct single-bottle method, and in bulk by the most modern methods developed in Europe.

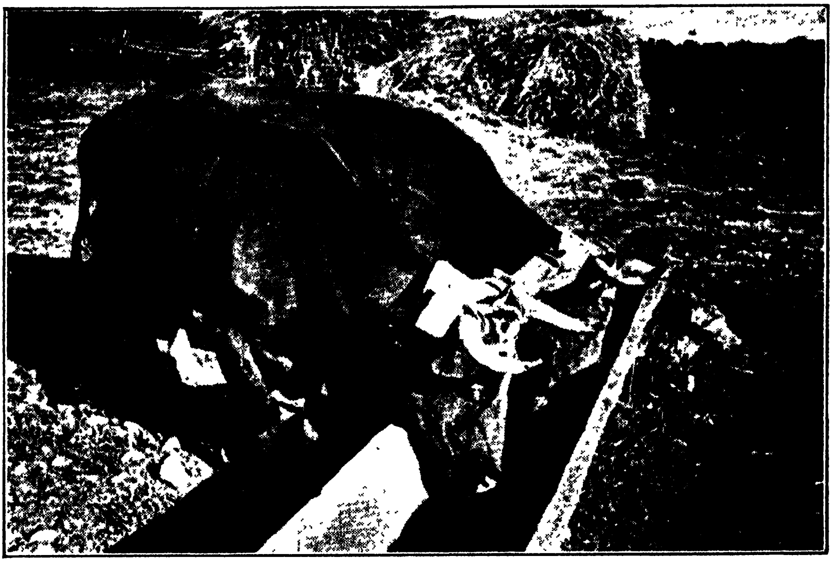
Home-Made Bullock Dray, as Commonly Used in many Country Districts of Chile.

Drays to be hauled by a pair of bullocks are general throughout Chile, and in many places are made from timber available on the farm or in the locality. The wheels are a simple section of a log, and even the axles are of wood. Axles do not last long, and are replaced by similar kinds as they wear out.

Exports of wine from Chile are on the increase, the principal countries buying them being Belgium, Germany, Holland, the neighbouring countries in South America, and the United States of America.

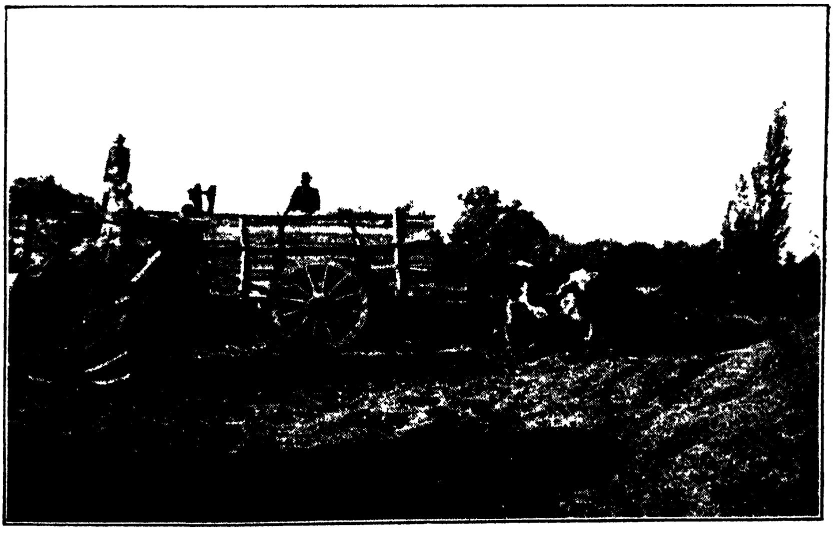
FRUIT-GROWING IN CHILE.

The growing of fruits suitable for a Mediterranean climate has always been important in Chile, but since the export of the fruits has been undertaken under proper methods a great increase in the area planted has taken place, and it can be confidently expected that this country will eventually become a really prominent producer of certain fruits. As to be foreseen, grapes, olives, almonds, figs, apricots, peaches, nectarines, apples, pears, cherries, plums, and walnuts do well in some portion of such a country, with its climate varying from rainless, through semi-arid to Mediterranean, and shading into cool temperate with heavy rainfall. At present grapes are important from an export point of view for wine, dried grapes and fresh grapes, and a lot of apples and walnuts are sold out of the country, and although the exports of other kinds of fruit have not yet reached considerable dimensions some of all kinds is sent away, and the quantity is increasing year by year.



Looking on Top of Yoked Bullocks to Show the Method of Attaching Yokes to Horns.

Each yoke is specially made for the pair of bullocks to which it is to be attached, the grooves to take the greenhide thongs being so placed that the yoke is kept off the necks of the animals when tightly laced to the butts of the horns.



The Primitive and Modern.—A Two-Bullock Dray Brings the Crop to be Threshed to a Power Thresher, Driven by an Up-to-date Tractor.

In the cooler parts of Chile the conditions are too cool for the effective tramping out of the grain from the crops, so power threshers are used, although most other harvesting operations are still conducted along primitive lines.

The Government has opened fruit-canning schools, where suitable pupils are taught modern methods of canning fruit. Good quality fruit is grown in the country and the authorities are endeavouring to ensure that the surplus which already exists will be presented to prospective buyers in an attractive as well as a wholesome form. The canned pears and peaches tasted at the canning school were of good texture and flavour, and were excellently preserved.

CEREALS IN CHILE.

Although Chile is, in a general way, a hilly to mountainous country, a fair quantity of the more important cereals is grown. At one time enough wheat was produced to enable a handy surplus to be exported, but this has dwindled to such an extent that the country is just about self-supporting with this cereal. The crop of barley and oats is always in excess of local requirements, and somewhere between 12,000 and 60,000 tons of grain of each cereal is available for export each year. A large increase in the area sown to wheat, barley, and oats was brought about between 1909 and 1914, but since that time relatively little increase has taken place, as can be seen in the next table:—

A Busy Harvest Scene in Chile.

Sheaves of a ripe wheat crop have been carted to a thresher in a bullock dray, and many hands are required to conduct the threshing operations.

Progress of Cereal Growing in Chile.

NOTE.—In translation hectarea taken as 2.47 acres, and metric quintal as 220lbs.

YIELDS OF THE CEREALS.

The yields received from the cereals in Chile are not comparable to those of most other countries, because so much of the wheat and barley crop is irrigated, in the case of the former it is about 22 per cent., and of the latter as high as 63 per cent. For the twenty-four year period ending in 1933 the relatively high average yields of 17bush. 50lbs. per acre for wheat, 30bush. 10lbs. per acre for oats and 31bush. 20lbs. per acre for barley have been recorded, details of which are to be seen below:—

*Yield per Acre of Principal Cereals in Chile.**

Year.	Yield per Acre.					
	Wheat.		Oats.		Barley.	
	Bush.	Lbs.	Bush.	Lbs.	Bush.	Lbs.
1909-10	23	18	21	24	41	33

TYPES OF CEREALS GROWN IN CHILE.

The wheats and barleys grown in Chile are almost identical in type to those grown in Australia. Of wheats about 95 per cent. are "white" wheats quite similar to Australian varieties, and as a matter of fact some of our well-known kinds are prominent in Chile, notably Florence and Australiana (probably Currawa), whilst Major and Waratah were also seen. The remaining 5 per cent. of wheat consists of red wheats similar in type to those found in Argentina. Of barleys, about 63 per cent. are six-rowed "feed" kinds very similar to those known as Cape, Malting Cape, Six-rowed, &c., in Australia, whilst the remaining 37 per cent. consists mainly of Chevalier type malting barleys, somewhat like Prior.

Most oat crops seen were of the heavy-yielding European types of a white or almost-white colour, and as the oat crops are grown towards the south, where the rainfall is sufficiently heavy for this cereal and irrigation is unnecessary, there is no need for Chile to grow the Algerian type of oats so suitable for the semi-arid areas of Australia.

Opening-Up Furrows for Irrigation in a Crop with a Single-Handled Plough Drawn by Two Bullocks.

In Chile most of the cultivation work connected with crops, which is not done by hand implements, is carried out by teams of two bullocks with yokes attached to the animals' horns. The principal implement seen in many parts of the country is a wooden plough made from a bent limb of a tree, and shod with iron, the implement being almost as primitive as those used in Bible times.

A little rye is grown in Chile, but it is not an important crop in any way, and it does not appear as though it will ever occupy a prominent position among the crops of the country.

Types of Wheat and Barley Harvested in Chile in 1931-32.*

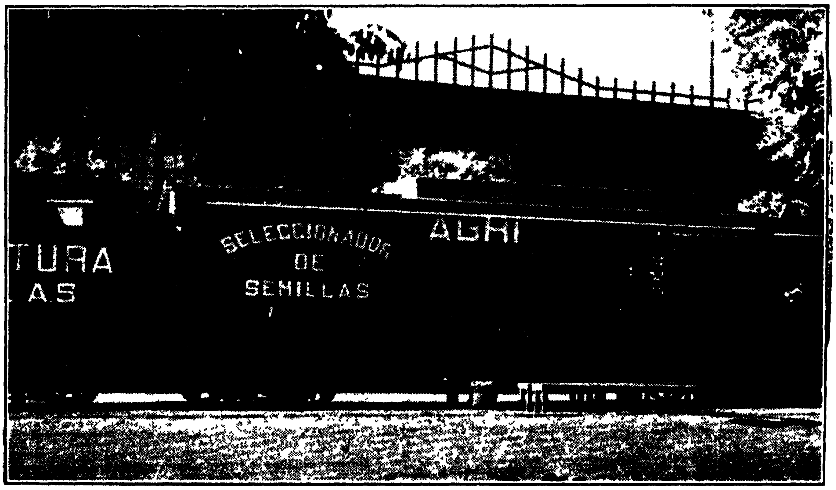
NOTE.—In translation metric quintal taken as 220lbs.

HARVESTING CEREALS IN CHILE.

A great deal of the harvest work connected with the collection of the cereal crops is still carried out in a most primitive fashion. Much of the crop is cut with the sickle when ripe, is tied into large sheaves which are stood up on their butts, not in stooks as binder-made sheaves are packed, but each one separately. When dried right out they are stacked on the threshing floor in a circular stack, and then a fence is erected parallel to the edge of the stack and some few yards away from it. When the crop is being threshed unharnessed farm animals are driven round and round the space between fence and stack and men and women throw sheaves of the crop from the stack under the feet of the moving animals. When the grain has been tramped out of the heads it is winnowed by throwing or brushing it into the wind.

Power threshers are used in large numbers in the cooler parts of the country, as the crops are heavy and the ground and climate too cool and damp for the effective tramping out of the grain. It is a common sight to see the primitive and modern side by side at harvest time; crops cut with sickle, carted to thresher in a home-made bullock-dray with wooden axles, drawn by two oxen, and the threshing done by an up-to-date thresher driven by a powerful motor tractor.



Grain Graders Mounted on Railway Cars on the State-Owned Railways of Chile.

These grain graders are taken through the wheat-growing districts of the country grading agricultural seeds for farmers at a low cost. Besides these, the Department of Agriculture of Chile has several of the same make of grain grader, mounted on motor lorries, to grade the seeds of farmers located some distance away from the railway lines.

Binders are used to cut the cereal crops on some farms but their use is by no means general in the country. It will probably be some time before truly modern methods are utilised to the full, because there is a large rural population in Chile which at present gets its living by farm work, and until many of the persons can be absorbed in other jobs, full advantage cannot be taken of modern farm machinery.

ENCOURAGING CEREAL GROWING.

The Government is doing everything possible to encourage farmers to improve their crop-growing practices, and is particularly interesting itself in the improvement of cereal growing. Besides opening up cereal breeding and crop selection stations, well equipped and adequately staffed, from which to distribute better quality seed, the Department of Agriculture sends grain grading machines throughout the agricultural districts, and grades the farmers' seed at a very low cost. Enclosed railway cars have been equipped with "Petkus" grain-grading machines, and three of these tour all of the cereal growing districts served by railways, while seven similar plants have been fixed to motor lorries to help grain growers located some distance away from the railway lines. Farmers have taken very kindly to the scheme and officials are looking forward to a noticeable improvement in the cereal crops as the result of this work.

VEGETABLES IN CHILE.

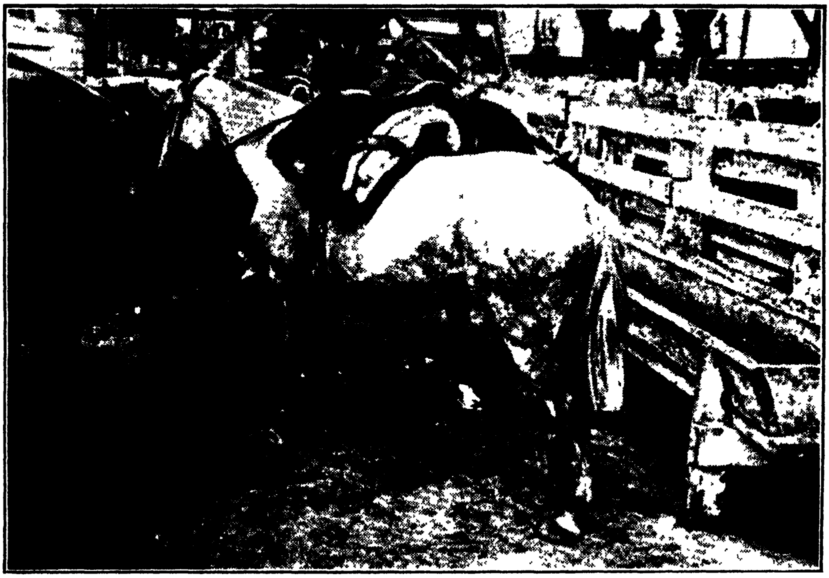
Enormous quantities of vegetables are grown in Chile, and market gardeners are quite expert at their calling. Kidney beans are the staple diet of the populace, and as large quantities are exported as well, the area planted with this crop is considerable indeed, and as a matter of fact almost everywhere in Chile where crops are grown beans appear very prominently. About three-quarters of the area sown is irrigated, but in those southern districts, where frosts admit of the crop, sufficient rain is received to mature heavy crops of beans. A large assortment of varieties is grown, all of which are good human foodstuffs. Besides beans, peas and lentils are produced in large quantities, both for local consumption and for export, and although a fair proportion of the area sown to lentils is irrigated, nearly all of the peas are grown where the rainfall is sufficient. Onions are used in large quantities in the country and a good export trade to the United States of America is being worked up with onions and garlic. Of recent years sweet melons have been grown most successfully, and as well as the great quantity consumed locally, exports, mainly to the United States of America, have reached thousands of tons a year. Considering that the potato is indigenous to Chile, it is to be expected that large quantities would be produced in the country, and for local consumption it is so, but the amount exported is not very great. The tubers offered for sale in the markets were very small indeed, and not of the quality of the onions and melons, which was very high. Chillies, or *Capsicums* from which cayenne pepper is made, are consumed in enormous quantities, both green and ripe, and the quality of those exposed for sale was invariably good.

OTHER CROPS.

Although practically all crops suitable for the conditions are grown in Chile, few others than those already mentioned have yet reached a prominent position. Of the others, maize has been an important crop for a very long time, as maize grain is one of the principal foods of certain sections of the people, and a fairly considerable area is sown for green forage and silage each year. All told, over 100,000 acres are sown yearly, and most of it is produced with artificial irrigation. Hemp growing is becoming popular in the country, and under irrigation it does well in the conditions. Quite a fair amount of hemp seed is exported each year. Strawberries, which are indigenous to southern Chile, are grown to some extent, but do not appear to be nearly so popular, in this their natural habitat, as they are in some countries which have adopted them as a fruit. Red clover does particularly well in portions of the country, and appears as if it will become increasingly important as the forest growth is removed from the volcanic soils in the heavy-rainfall districts of the south.

IRRIGATION IMPORTANT IN CHILE.

It is estimated that about 3,000,000 acres are farmed with the aid of irrigation by private people, and that about another 1,000,000 acres, which are under Government schemes of some kind, are also artificially watered. To Australians these figures are immense and give some idea how very important irrigation is to Chile, but judged by the enormous quantity of perfectly fresh water from the melting snow of the Andes which finds its way to the sea in almost countless small streams, as well as in a few fair-sized rivers, there are very great possibilities of expansion of irrigation farming. Portions of most valleys in the area which extends a couple of hundreds of miles north and south of Valparaiso, are growing crops with irrigation, the water being conveyed in open earth channels contoured to take the water wherever it will run. A large assortment of crops is raised with the help of water, the principal ones being vines, fruits of several kinds, beans, lucerne, maize, barley, potatoes, and vegetables of most kinds. Near the city of Santiago, included amongst the vegetables, are large areas of Globe artichokes on quite a number of holdings, and some gardens appear to grow little if anything other than this crop. Much of the land in this relatively low-rainfall area consists of free-working soils of high fertility resting on coarse water-worn gravels, and so has good natural drainage, but on the other hand, because of the looseness, requires frequent and liberal waterings. Most of the irrigation settlements are fairly old, still there is no evidence of an excessive rise of injurious salts, the water being so fresh and the natural drainage of the soils so good that this trouble, so common in hot, semi-arid climates, does not operate. In some localities red clover is grown as well as lucerne, and numbers of farmers prefer the clover to the lucerne, both on returns and on the quality of the feed.

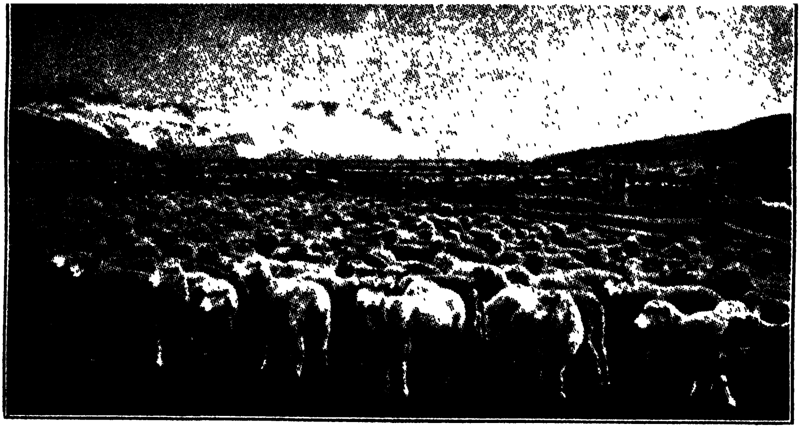


Stock Horses, showing Typical South American Saddles.
The saddles consist of a framework on which are packed three or four sheepskins, kept in position by a surcingle. These saddles are veritable leg-spreaders, but for country stockmen provide useful beds when spread out after unharnessing the horses.

WEEDS SEEN IN CHILE.

The weeds seen along the roadsides, on farms, and in gardens are identical with those commonly found in southern Australia, and their presence is a true indication of the similarity of the climates of the two countries. In the southern districts, where the rainfall is heavy, the Blackberry (*Rubus fruticosus*) is extremely bad, growing so strongly in some localities that it is competing with the natural forest. Bathurst Burr or Horse Burr (*Xanthium spinosum*), which is indigenous to the country, and Bindweed (*Convolvulus arvensis*) are two troublesome weeds in several localities. Of weeds well known in Australia the following were seen in great quantities:—Wild Oats (*Avena fatua*), Barley Grass (*Hordeum murinum*), Sea Barley (*Hordeum maritimum*), Fennel (*Foeniculum vulgare*), Rooted Cat's-ear (*Hypochoeris radicata*), Chicory (*Cichorium intybus*), Wild Artichoke (*Cynara carduncnlus*), Saffron Thistle (*Carthamus lanatus*), Variegated Thistle (*Silybum marianum*), and Docks (*Rumex* spp.), whilst lesser quantities of Water-couch Grass (*Paspalum distichum*), Purslane (*Portulaca oleracea*), Petty Spurge (*Euphorbia peplus*), Wild Turnip (*Rapistrum rugosum*), and Buchan Weed (*Brassica adpressa*), were encountered in several localities. There was a noticeable absence of leguminous plants amongst the weeds, the only one noticed at all in the drier parts of the country, and that in gardens only, was King Island Melilot (*Melilotus indica*). In the southern end of Chile where the rainfall is heavy, Red Clover, White Clover, and Cocksfoot are behaving as strong-growing weeds, as they do in parts of New Zealand.

A Flock of Pure-Bred Corriedale Sheep at "Chacabuco," in Chile.
Corriedale sheep are doing well in parts of Chile, and fairly large numbers of high-class animals of the breed have been imported from New Zealand into the country in recent years.



[From *Bulletin of the Pan American Union.*

A Flock of Sheep Typical of the District of Magallanes, in the South of Chile.
Nearly half of the sheep of Chile are maintained in the Magallanes district, and from this part of the country about 60 per cent. of the wool is produced, as well as nearly all the carcasses of mutton and lamb which are exported overseas.

SHEEP IN CHILE.

There are about 6,500,000 sheep in Chile, of which number about 40 per cent. are maintained in the Magallanes district to the south of the country. Very few Merino sheep are kept, but long-woolled breeds like Lincolns and Romney Marsh are prominent, and Corriedales have been imported in large numbers of recent years from New Zealand. Sheep breeders in Chile had just commenced to take a serious interest in flocks of Merinos, but the imposition of the embargo on the exportation of stud Merinos from Australia reduced the chances of the breeders making rapid progress in the improvement of the local sheep of the breed. Some of the country of Chile is ideally suited for Merinos, having Mediterranean climate, being of a hilly nature, and possessing red-coloured, heavy-textured soils of high fertility.

The census of 1930 disclosed that the 4,600,000 sheep shorn that year produced 26,680,000lbs. of wool, and of this quantity about 60 per cent. came from Magallanes, at the extreme south of Chile. Practically all of this wool is of coarse texture, and not comparable to that from Merino sheep.

CATTLE IN CHILE.

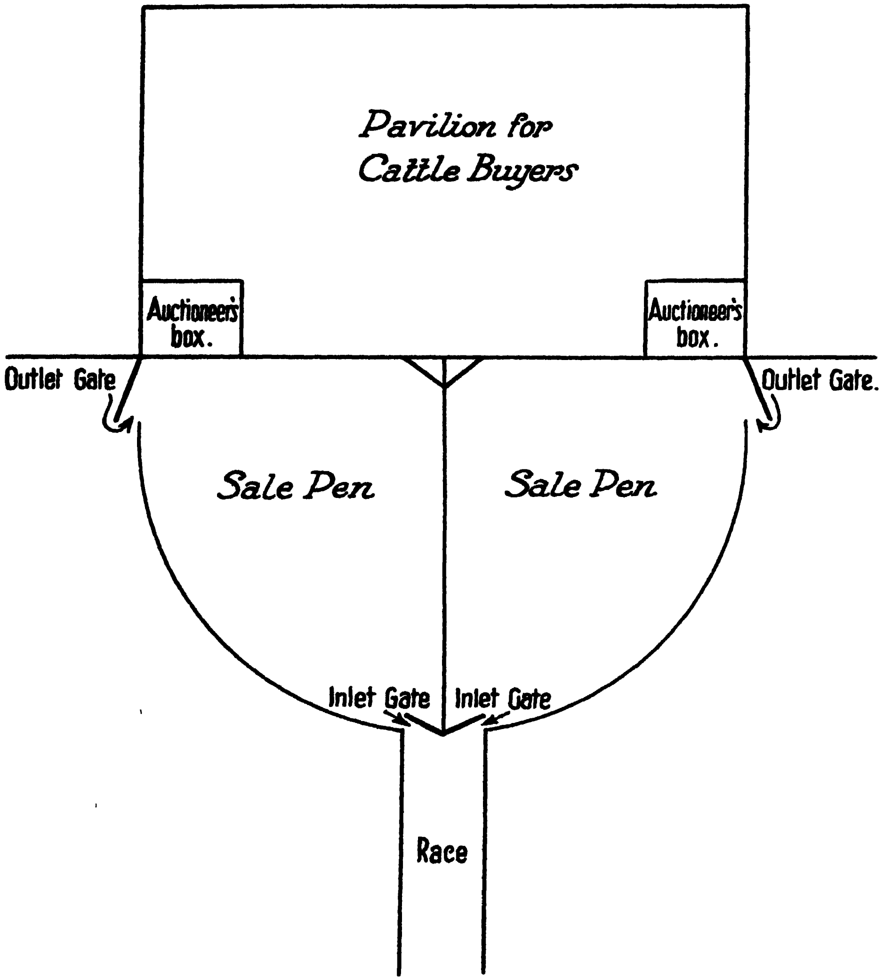
Although it is freely stated that Chile is a good cattle-producing country she does not breed sufficient animals to supply her own beef requirements, and importations from over the border are necessary. Considering the natural conditions obtaining in the country this is to be expected, and when strong-growing pastures are developed it will probably prove more economic to keep cattle for the production of milk rather than for beef, and to continue to import meat from the neighbouring countries where the conditions are so highly favourable for beef cattle.

Cattle Held Ready for Sale in a Pen in the Cattle Sale Yards at Temuco, Chile.

Papers with printed numbers on them are stuck on the top of the hindquarters of each beast before sale, which does away with the job of marking the animals with paint or tar after they are sold. The square papers can be seen on several of the cattle in the illustration.

There are about 2,500,000 head of cattle in the country, which is only a slight increase in numbers during the past 25 years or so, and of these the animals kept for dairying purposes are largely of the Friesian breed, whilst the beef cattle are mixtures of various kinds, a high proportion appearing as though more suitable as work oxen than as producers of quality beef.

A convenient and rapid method of selling bullocks one at a time is practised in Temuco, a fair-sized country town in the south of Chile, and is rendered possible by the arrangement of the selling yards. Cattle buyers sit in a rectangular pavilion with seats banked steeply one above the other, at the front of which are located two selling yards, each being half the width of the pavilion, and are rounded and in shape somewhat like a quarter of a circle. At each of the front corners of the pavilion is an auctioneer's box, the ground plan of the pavilion, sale pens, and auctioneer's boxes being as follows:—



Ground Plan of Cattle Saleyard at Temuco, Chile.

Not to Scale.

A beast is brought into one sale pen and the auctioneer overlooking that pen calls for bids, and whilst selling that animal another is brought into the other sale pen. As soon as the first animal is sold the other auctioneer commences selling the beast in his yard, and this goes on alternately. In each sale pen is stationed a cattle drafter on horseback, and the horses used are very expert in helping to keep the animals towards the buyers. The mucky job of branding the cattle with tar or paint after sale is eliminated at this saleyard, for paper numbers are stuck on the top of the hindquarters of all beasts some time before they are offered for sale. This has the added advantage of giving prospective buyers the certainty of knowing the animals when they come into the pen for sale after having leisurely inspected them beforehand. The papers carrying the numbers are about 5in. square and the figures about 2in. in height.

DAIRY PRODUCTS IN CHILE.

The census of 1929-30 showed that there were 282,415 milking cows in Chile, and that during the year 60,454,020galls. of milk were produced. Of manufactured dairy products 3,442 tons of butter and 2,458 tons of cheese are recorded

A Corner of a Modern and Up-to-Date Milking Shed at Los Andes.
Although much of the agriculture of the country is conducted on primitive lines, some of the properties are most efficiently managed. The sheen of the floor of the shed illustrated, with the piping framework and fittings, swivel bails, and cement concrete feeding troughs, show modernity of equipment and efficiency of management.

for that year in Sinopsis Geográfico-Estadística de la República de Chile. Since that time considerable progress appears to have been made, and this largely because of the extension of large dairies, conducted by private individuals and syndicates on the most modern and hygienic lines. Although so much of the dairying of Chile is practised on very primitive lines some efficiently conducted dairies were seen, and one in particular (Baburizza and Pcrinovic's dairy farm at Los Andes) would be hard to fault, and especially the effort to keep down contamination of the milk in the milking shed. On arrival in the shed the whole of the hindquarters of each cow is washed and scrubbed with a brush from a line in front of the udder and over the back, including the hips, particular attention being given to udder and tail. When the last cow in the milking shed was washed, and not before, the milk girls, dressed in snow-white overalls, were allowed to commence milking, and throughout the period of milking youths patrolled the shed removing the droppings of animals as soon as evacuated.

A considerable change in the methods now followed in dairying by those conducting the business on a small scale will be necessary before Chile can become an important dairying country, but the possibilities for the development of luxuriant pastures in districts with mild climate are so great that eventually cheese, butter, casein, and other dairy products must be of great value in this Republic.

Other than a few crossbred animals practically all cows maintained on dairy farms are of the Friesian breed, and some exceptionally good animals are to be found in Chile. Breeders of Friesians keep up the standard of their herds by frequently importing bulls from Germany and the United States of America, some herdmasters preferring the stronger and more beefy Dutch type to the finer-boned more highly-strung American Friesians. Few high-production herds can be heard of in Chile, because it is a common practice to rear the calves on the cows, and so only a proportion of the milk produced by the cows is extracted by human beings.

SUMMARY OF IMPRESSIONS GAINED IN CHILE.

1. Chile is a long narrow country, being 2,661 miles in length, averages about 100 miles in width, and has a coastline of 2,800 miles.
2. About three-fifths of Chile is of a mountainous nature.
3. A large proportion of the north end of Chile is rainless or almost so, but the rainfall becomes gradually heavier and heavier towards the south, until over 120in. per annum are received in some localities.
4. In most parts of Chile where rain does fall, Mediterranean climate is experienced, and the bulk of the rain falls in the winter.
5. Rural practices are still very primitive in many districts of Chile, but on some of the larger holdings modern and thoroughly up-to-date methods are in use.
6. Although about three-fifths of the country is mountainous, there are still over 70,000,000 acres of land suitable for agricultural pursuits.
7. Possessed with Mediterranean climate, plenty of irrigation water, and considerable areas of fertile land, it appears certain that Chile will eventually be an important producer of wine, fruit, olive oil, nuts, dairy produce, and sheep, as well as raise fair quantities of cereals, legumes, and maize.
8. The principal agricultural items being exported at present are wine, cereals, legumes, onions, melons, apples, wool, and meat.
9. For a very long time, Chile has been noted as a producer of wines of extremely fine quality.
10. There are nearly 35,000 registered vinegrowers in Chile, and the area planted with vines is 211,484 acres.
11. The production of wine fluctuates between 50,000,00galls. and 74,000,000galls. per year, and exports reach 1,500,000galls. a year.

12. About ·38 per cent. of the vines grown in Chile are irrigated.

13. Since the export of fruits has been undertaken under proper methods a great increase in the area planted to fruit trees has taken place.

14. About 63 per cent. of the barley crop, and 22 per cent. of the wheat crop are irrigated.

15. The wheats and barleys grown in Chile are similar in type to those grown in Australia, but the oats are of European type.

16. A fair quantity of oats and barley is exported each year from Chile.

17. Most of the cereal crops are cut with the sickle, and a good deal of them are threshed by tramping with livestock, and then winnowed in the wind.

18. The Government sends grain-grading plants around the country districts to grade seed for farmers.

19. Enormous quantities of vegetables are grown and consumed in Chile. Beans are a staple diet of the populace, and large quantities of peas, lentils, onions, melons, and chillies are also eaten.

20. Maize has been an important crop of the country for years, and the grain forms one of the principal foods for certain sections of the community.

21. Red clover does particularly well in portions of the country, and is likely to become more important in the future.

22. Irrigation is practised on a considerable scale in Chile, and the possibilities of extending this type of agriculture appear to be very great.

23. Most of the weeds commonly known in southern Australia are prevalent in Chile, and their presence is an indication of the similarity of the climate in the two countries.

24. There are about 6,500,000 sheep in Chile, mostly of the long-woolled breeds, such as Lincoln and Romney Marsh, but Corriedales are gradually becoming prominent.

25. Chile possesses about 2,500,000 head of cattle, but has to import meat from across the border.

26. Except on some of the large holdings, most of the dairying of the country is conducted on primitive lines.

27. Other than for the presence of a few crossbred animals, practically all of the cows used for dairying purposes are Friesians.

FARMERS' DAY AT KYBYBOLITE.

Farmers' Day, which is held annually at the Kybybolite Experimental Farm, still attracts a large number of visitors from all parts of the South-East and the Western Districts of Victoria. This year's gathering, which took place on 13th November, was attended by approximately 300 to 400 farmers and graziers. Included amongst the visitors were the Minister of Agriculture (Hon. A. P. Blesing, M.L.C.), Messrs. Petherick, Hunt, Crosby, Connor, Dennison, and Dunks, M's.P., P. J. Baily and S. Shepherd (Members of the Advisory Board of Agriculture), Professor A. J. Perkins (Director of Agriculture), Dr. A. E. V. Richardson (Director Waite Institute), and officers of the staff of the Department of Agriculture.

Under the guidance of the Manager of the Farm (Mr. L. J. Cook), the visitors inspected the various experimental plots, and lectures were given by Dr. Richardson, Messrs. H. B. Barlow, R. C. Scott, and C. McKenna, B.V.Sc.

The Minister presented Mr. Shepherd with a Life Membership Certificate of the Agricultural Bureau.

VITAMINS AND OTHER FACTORS IN THE FEEDING OF BIRDS.

[By EDGAR W. PRITCHARD, Dip. Econ., Agricultural Botanist and Seed Analyst.]

There are six or seven vitamins at present known, but the following three are of great importance:—

1. *Vitamin A,* which keeps the eyes healthy.
2. *Vitamin B,* which is required to maintain a healthy nervous system.
3. *Vitamin C,* which prevents scurvy.

Taking the commoner bird foods:—

(1) Most seeds contain a little of Vitamin A, and are specially rich in Vitamin B.

(2) Green leaves of all kinds contain all three vitamins, as does also milk, if the cows receive some greenfeed.

(3) Fresh meat contains a small amount of all three, suet and beef fat some of Vitamin A, but none of the others, while liver is rich in all of them. The marrow of bones is also said to be rich in some of them.

(4) Of food for honey birds, white sugar and honey contain none, and brown sugar and treacle a little.

Seeds are by far the most important item of food for cage birds, for these are packed full of pure, concentrated, easily digested material, ready for the nourishment of the young plant, and equally suitable for the nourishment of birds and animals. But there is one important point about seeds which is often overlooked. It is that they should be fresh. The most highly nourishing part of the seed, especially from the point of view of vitamins, is the germ, the minute embryonic stem, root, and leaves, from which the young plant shoots. This germ is alive, though dormant, and in it is contained a small amount of Vitamin A.

But the germ only lives for a limited time, usually from five to 10 years, and after that, or even a year or two before, the seed is dead, and not fit for the nourishment of either birds or human beings. When dead, the seed begins to decay, mould fungi gain an entrance, the vitamins vanish, and the seed gradually becomes musty, and unpalatable, and in the end actually dangerous.

This is a point which needs careful watching, as some bird seed on the market is simply seed which was intended for sowing, but has been kept till it is too old to germinate, and is then thrown on the market as cheap bird seed. It can be truthfully said, that seed which is not fit to put into the ground to produce a crop is not fit food for man, animal, or bird.

To obtain an estimate of the real quality of the bird seed on the South Australian market, samples of seeds as they come in from overseas have been subjected to germination tests in the Seed Testing Branch of the Department of Agriculture. Following are some of the results, each figure representing a different sample:—

Germination of Imported Seeds.

	Per cent.
Hemp (from Japan and Manchuria) .	90, 82, 81, 78, 77, 75, 75, 52, 39, 16, 14, 6, 5, 0.
Canary (from Turkey)	99.
Millet (from Japan and Manchuria) .	100, 99, 92, 91, 88, 86, 83.
Sunflower (from South Africa)	92, 92, 90, 82.
Rape	77 (from Japan), 22 (from New Zealand).
Turnip (from New Zealand)	54, 28, 27.
Maw (from South Africa)	52.
Niger (from South Africa)	95.

No canary seed has been imported into South Australia from overseas for about three years.

All the lower results in this list showed much fungus growth, whereas the good samples were practically free from it. The poor quality of rape and turnip seed from New Zealand is very noticeable, because it is probably seed for sowing, which has become too old to pass the test.

From these results it will be seen that bird seed varies very considerably in quality, even when it is first imported, and it is certainly not likely to improve by keeping.

The next division is greenfeed, and this is the most important of all from the point of view of vitamins. Green leaves, both of herbs and grasses, contain all three of them. Greenfeed should be supplied fresh every day, because one of the vitamins is destroyed by drying, and besides, if left lying in the cage for any time, it will ferment, and thus become a dangerous poison, especially to birds which have lived in captivity for only a few generations.

Almost any kind of green grass, including millet and maize, will answer the purpose, and also such succulent herbaceous plants as kale, rape, cabbage, lettuce, silver beet, spinach, New Zealand spinach, clovers, peas, lucerne, and tree lucerne. There are also a few poisonous weeds, which should be carefully avoided. The worst of these is perhaps the Petty Spurge, a very fresh green succulent deceiver, with almost circular leaves, and minute yellow flowers. It is found in almost every suburban garden, and frequently grows among grasses and clovers and other green stuff. It can be identified by breaking the stem sharply across, when a milky juice will exude. This juice is a strong caustic poison. It will cure warts at one application, and will raise blisters on the hands in weeding, if it is at all plentiful. It should be avoided like poison. There are other species of spurge, with the same general appearance, but larger, and the same milky juice, which are all poisonous, but not so plentiful. Also all kinds of liliaceous plants, such as irises, daffodils, amarylis, watsonias, ixias, cannas, &c., should be avoided. They are all more or less injurious, though not so virulent as the spurges.

Next, we come to mixtures, of which I understand a certain amount is commonly used. The first and most important point from the point of view of vitamins is that, where wheat flour is an ingredient, it should be fresh, coarse ground wholemeal, and not the devitalised residue, which the housewife so much delights in for the production of her beautiful light fluffy spones. Wholemeal contains roughly *three* times as much lime, *five* times as much phosphates, and *four* times as much iron as white flour, and also a large amount of Vitamin B, of which white flour contains none at all. It has been proved that pigeons fed on white flour die quicker than if actually fasting. The same remarks apply to the majority of biscuits.

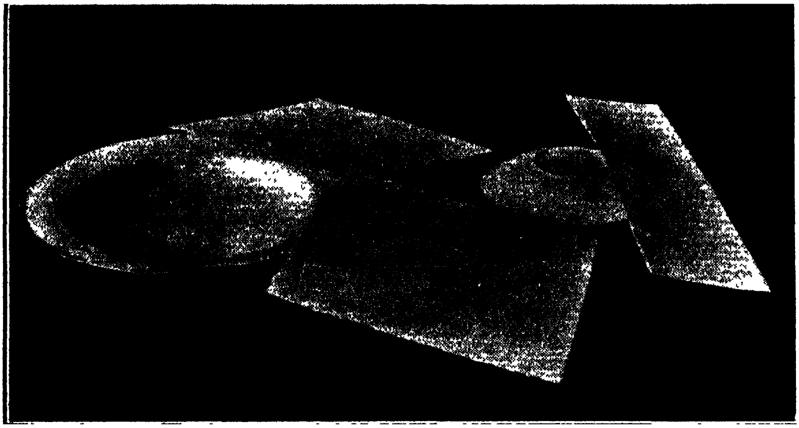
Also, the wholemeal should be freshly ground, if it is to represent adequately the whole wheat grain. All wheat contains a small amount of oil packed closely round the germ which begins to go rancid after about six weeks.

For honey birds, honey itself would seem to be the natural food. But it must be remembered that the nectar of the flowers is considerably changed in the honey sack of the bee, and during storage in the hive, being converted largely into fruit sugars. Nectar itself is almost pure cane sugar with the addition of some mineral salts, and probably some vitamins. Ordinary white sugar is too highly purified for the sake of appearance. So probably brown sugar would answer the purpose best. Honey is worth experimenting with, as it is at least pure, easily digested, and contains all the mineral salts of nectar.

The feeding of honey birds must, I should think, be rather a difficult problem, for most of them eat a large number of insects to balance up their diet. Nectar is wholly carbohydrate, and insects wholly protein and fat, so with the two combined, it is possible to get a balanced diet. It must, however, be difficult to provide live insects. And I can only suggest for trial, a mixture of brown sugar, 4ozs., and milk one pint, or brown sugar 4ozs., and raw egg (yolk and white) 6ozs., both diluted with water to the proper consistency. This would give a well balanced diet, and one easily digested by organs not accustomed to starchy foods. A small amount of fruits in season would complete the vitamin supply, and whole milk powder with a little dried or fresh orange juice, could be substituted for the fresh milk.

In regard to carnivorous birds, or those which live entirely on insects, the vitamin supply is really the most difficult problem. But with a fair supply of liver, and if possible, some bone marrow, the situation should be fairly secure. A little fresh whole milk should complete the security. Milk is the chief of what are called "the safety foods" in regard to vitamins.

Finally, as to practical methods of dealing with the food supply of birds, illustrated below is a home-made seed germinator. It consists of a porridge plate, a saucer, and some pieces of soft cloth or blotting paper. First, the narrow strip is folded round the saucer as shown; the saucer is then placed bottom upwards in the porridge plate, and water is added until the saucer is nearly covered. Then one of the squares is evenly moistened with water, and placed on the rim of the porridge plate, and pressed in the middle till it also touches the saucer. One hundred seeds are then arranged on the square, and covered with the second square, and the whole is put away in a cupboard which, if possible, should be well lighted. From five to 14 days are required for the final result, according to the variety of seed.



It is thus a simple matter to test all kinds of bird seeds for freshness, as well as for general qualities, such as the presence of shrivelled, old, and diseased seed. And it should surely be worth while, especially where seeds are bought in bulk. Seeds for sowing are required to give a germination of not less than that set out in the table below. The standard for bird seed should be nearly, if not quite, as high.

Germination Standards for Seeds.

	Per cent.		Per cent.
Barley	80	Niger	80
Canary	65	Oats	80
Hemp	65	Panicum	70
Linseed	65	Peas	75
Maize	80	Rape	70
Maw	80	Sunflower	65
Millett	75	Turnip	70
Mustard	60	Wheat	80

To summarise in a few words, the question of vitamins in the feeding of birds resolves itself into the following points:—First, making sure that all seeds are fresh and properly matured; second, a daily supply of fresh greenfeed; and third, for insect-eating birds a fair amount of fresh milk, and for carnivorous birds of fresh liver.

This BETTER tractor fuel is BRITISH

As Britain is Australia's best customer it is fair enough to suggest that Australian primary producers should use a British-Australian tractor fuel. And by using "C.O.R" Power Kerosene you'll work more acres per gallon and gain smoother, trouble-free running.

Available in convenient 24-gallon drums.

THE PREPARATION OF EXPORT FRUIT.

[By E. W. REVELL, Fruit Inspector.]

During the past three or four export seasons, considerable improvement has occurred in the general appearance and get up of our export fruit. Attractive labels are being employed, and the standard case is now used almost exclusively; in so far as external appearance is concerned, exporters are submitting a good article, but there is undoubtedly still room for further improvement in preparation of the pack.

Every year an appreciable quantity of fruit is rejected by inspectors on account of well known defects such as—Black Spot, excessive hail-marks, Codling Moth, over-maturity, slack pack, bruising, &c., &c. Many such rejections could be avoided if the growers concerned would fully acquaint themselves with the requirements of the regulations, and then endeavour at all times to prepare a pack which is *superior* to that required by the regulations.

The necessity for careful picking has been stressed innumerable times, and yet many growers still pick fruit into unsuitable receptacles, and dump it from case to case with no appreciation of the damage they are doing. Bruising which can be traced back to the orchard is considerable, and is a frequent cause of shipside rejection. Even during packing operations much bruising may occur, and care should be exercised not to rush fruit so quickly through the grader that it is bruised in the process. Several lines of excellent Granny Smiths were rejected last season for bruising—some of the individual apples in these lines showed up to 14 separate small bruises—and the trouble was occasioned by rushed grading.

Strict and continuous supervision should be given to packers in order to ensure that fruit is not roughly handled at any stage. Individual apples or pears should be *placed* in position in the case with the absolute minimum of "thumping," and cases which have been packed too high should not be lidded in that condition on account of the bruising which may be so incurred. Whenever fruit does not approximate to the right height in the case, bruising or a slack pack will result, and it is always desirable to repack when fruit comes either too high or too low.

A large quantity of fruit is rejected every year for false labelling, and care should be taken that the particulars as to variety, size, &c., are branded correctly.

Corrugated cardboard, which is now used extensively in packing apples and pears, constitutes an excellent cover for pupating Codling grubs, and it is important that packed fruit be stored on clean floors, that Codling rejects should be kept right away from the packed cases, and generally, every care exercised to ensure that the grubs do not get into the cases after the fruit is packed. Last season, one submitted line of fruit showed heavy infestation of cardboard, one sheet alone containing over 60 grubs. Naturally, this fruit was rejected.

During transport of fruit to the wharfside, especial attention should be given to stowage on motor lorries; do not stack cases on the bulge; do not load so that cases overhang the sides of the truck, and above all, do not walk upon the cases.

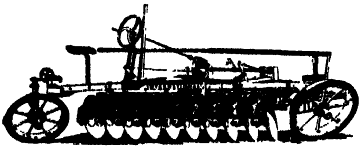
The Stevedoring Companies who have the responsibility of loading our fruit on overseas boats have gone to much expense in providing special gear to prevent fruit from being damaged or bruised whilst being loaded. Walking boards are placed over the cases stowed in the ship's hold, and immediate action is taken by inspectors against any wharf worker for rough handling the fruit in any way.

Power and Equipment - - - for Every Farm

You will not get the best results by using a first-rate tractor and second-rate implements. International Harvester provides a full range of tractors and implements for the most effective work on any property.

McCORMICK-DEERING WD-40 DIESEL TRACTOR

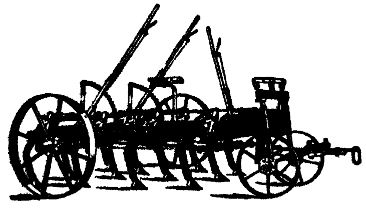
In the WD-40 triple-power tractor, McCormick-Deering engineers give the farmer the best he ever had in McCormick-Deering tractor quality—plus Diesel power that will cut the heart out of his fuel bills. Engine starts easily on petrol, switches automatically to low-cost Diesel fuel operation.



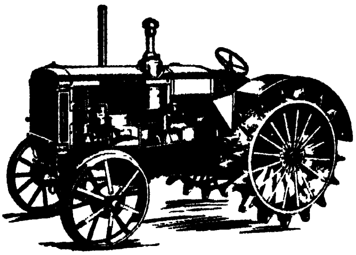
International Disc Cultivating Plough

McCORMICK-DEERING STUMP-JUMP MOULDBOARD PLOUGHS

These ploughs are built in 5 and 7-furrow sizes and can be adjusted to cut 6, 7 or 8-inch furrows. The jump beams or standards are one-piece high-quality steel with feet forged on the ends of the beams. These ploughs are supplied with short, medium, or long steel mouldboards, fitted with steel shares. For operation with tractor, a special power-lift attachment can be supplied at extra cost.



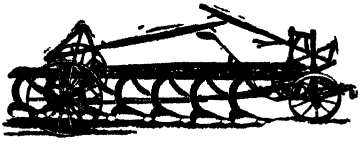
International Stump-Jump Scarifier



McCormick-Deering WD-40 Tractor

INTERNATIONAL DISC CULTIVATING PLOUGHS

The International single-jump disc cultivating plough is made in 6, 8, 10 and 12-furrow sizes, equipped with 22-inch discs spaced 9½ inches apart. A good plough for summer fallowing and ordinary ploughing. Width of cut can be varied from 5½ to 7 inches. This plough can be equipped for operation with horses or tractor.



McCormick-Deering Stump-Jump Mouldboard Plough

INTERNATIONAL STUMP-JUMP SCARIFIERS

Made in 5, 7, 9 and 11-ft. sizes, the International stump-jump scarifier has many serviceable features. It has ample clearance, is easy to operate—direct and positive in action. A splendid implement for cultivating fallow land. Can be equipped for use with horses or tractor.

INTERNATIONAL HARVESTER COMPANY
OF AUSTRALIA PTY. LTD.

(INCORPORATED IN VICTORIA)

113-114 NORTH TERRACE, ADELAIDE

M1102

It is most disheartening that, despite these precautions against rough handling during loading of vessels, truck drivers, and even orchardists who have grown and packed the fruit, are occasionally seen walking over cases during unloading from a lorry. It should be pointed out that anyone at all who walks over packed fruit, or roughly handles it in any way, is committing an offence under the Prevention of Injury to Fruit Act, and is liable to incur penalties provided for in that Act.

SOME IMPORTANT POINTS.

1. Wire tie all cases on the side and not on the bulge
2. Keep the tie wires close up to the cleats.
3. Do not nail lids on a flat surface; place battens beneath the case.
4. Stencil or label cases with a *true* description of variety, grade, and count or size.
5. From orchard to ship, handle fruit with the greatest of care.
6. Do not walk or sit on packed cases.
7. Aim at the correct packing height; either tight or slack packing results, ultimately, in bruised fruit
8. Stack boxes on their sides, and not on the bulge.
9. Do not incur the expense of packing and delivering at the shipside fruit which will not comply with export regulations.

TOBACCO GROWING IN SOUTH AUSTRALIA.

[By R. E. C. Giles (Tobacco Instructor).]

The production of tobacco seedlings in South Australia has been facilitated during the present season by the adoption of the Benzol method, advocated by the Council for Scientific and Industrial Research. Prospects for the further development of the tobacco growing industry in the State are much brighter.

F. Kuhl's Experimental Plots of Dungowan and White Stem Orinoco, at Penola

The accompanying photograph was taken during December, 1935, on the plantation of Messrs. Johnson Bros. of Comaum, South-East. The seedlings were grown by the Benzol method and have made remarkable growth since transplanting from the frames.

The variety is Spotted Gum and the land was dressed with 3-8-3 tobacco fertiliser.

This photograph of tobacco after five weeks in the field was taken on the property of Messrs. F. Kuhl & Sons, of Penola, after the seedlings had been transplanted from the seedbeds.

Spotted Gun Tobacco Plants grown by Benzol method at Johnson Bros.', Comaun.

This is typical of the country in the South-East which is producing good, bright cigarette leaf. The soil is of a sandy nature, overlying a clay subsoil, which holds the moisture well.

With freedom from the Downy Mildew or Blue Mould disease, tobacco-growing should soon be a firmly established industry in this area.

Manures.—In addition to 139,723 (148,923) tons manure used for crops as above, 17,466 (10,066) tons were used for top-dressing; the acreage top-dressed being Counties Adelaide 48,125 (34,374), Carnarvon 7,611 (5,544), Hindmarsh 50.051 (36,886), Light 6,055 (4,925), Sturt 14,246 (10,805), Buckingham 26,248 (10,192), Grey 66,644 (31,029), MacDonnell 35,710 (18,651), Robe 70,066 (46,553), others 35,835 (13,042), total 360,591 (212,001).

NOTE.—The maximum percentage of cropped area manured was 92·62 in 1929-30, and the maximum quantity per acre was 93·1lbs. in 1926-27. The area of 360,591 acres top-dressed for 1934-35 was a record, the previous highest being 302,114 acres in 1929-30.

ORCHARD, VINEYARD, AND MISCELLANEOUS CROP STATISTICS, 1934-35.

[Figures in parentheses refer to previous season.]

I. ORCHARDS.

1. *Acreage,* 29,167 acres (28,899 acres); increase, 268 acres. Trees of bearing age, 25,841 acres (25,640 acres). Approximately 800 acres grubbed, mostly in Counties Adelaide, 460 acres; Hamley, 140 acres; Stanley, 25 acres; Albert, 35 acres; and Frome, 30 acres. New planting, 1,070 acres, was an encouraging feature, chiefly in Counties Adelaide, 800 acres; Hamley, 45 acres; Light, 50 acres; and Hindmarsh, 50 acres.

2. *Production.*—Generally speaking the crops were a little lighter than the previous year, due mainly to hail and frosts in the Murray areas and dry winter conditions during 1934:—(*a*) Apples, 800,768bush. (1,002,124bush.), a decrease of 201,356bush. (*b*) Oranges (calendar year 1934), 638,314bush. (582,602bush.); increase, 55,712bush., surpassed the record established the previous year. Lemons, 47,761bush. (49,028bush.). Other citrus, 6,398bush. (5,275bush.). (*c*) Pears, 175,966bush. (211,458bush.), decrease of 35,492bush. (*d*) Apricots, 359,816bush. (396,993bush.), a decrease of 37,177bush. below the record of the previous year. (*e*) Plums and prunes, 190,365bush. (150,539bush.), being 6,760bush. more than the previous record of 183,605bush. in 1927-28. (*f*) Peaches, 146,411bush. (147,175bush.).

Details for other fruits are shown in accompanying table.

II. VINEYARDS.

1. *Acreage.*—53,361 acres (52,880 acres); increase, 481 acres. Vines of bearing age, 51,220 acres (51,042 acres). About 650 acres grubbed or died out, chiefly in Counties Stanley, 60 acres; Light, 210 acres; Adelaide, 175 acres; River Murray districts, 110 acres; but this was more than counterbalanced by new plantings—about 1,130 acres—chiefly in Counties Light, 120 acres; Hamley, 380 acres; Adelaide, 370 acres; Albert, 80 acres; and Stanley, 60 acres.

The acreage was described as follows:—For winemaking, 33,159 acres (32,451 acres); drying, 19,847 acres (20,065 acres), and table, 355 acres (364 acres).

2. *Total Grape Yield,* 147,680 tons (130,889 tons); increase, 16,791 tons. Average per acre of bearing age, 2.88 tons (2.56 tons). For winemaking, 70,836 tons (54,865 tons); drying, 76,198 tons (75,329 tons), and table, 646 tons (695 tons).

3. *Wine Made,* 13,200,000galls. (10,032,012galls.); increase, 3,167,988galls.; and 2,101,084galls. above the average of the previous five seasons, 11,098,916galls. Wine figures are subject to revision.

TRAVEL SERVICE.

A Commonwealth Savings Bank pass-book disposes of all the money worries that usually trouble the traveller.

Money can be transferred to any point, and withdrawn or deposited at any one of the Bank's 4,000 Branches and Agencies without cost.

Ensure the utmost convenience and safety by travelling, not with a dangerously large amount of money in your pocket, but with just your pass-book to see you through.

Commonwealth Savings Bank of Australia

(Guaranteed by the Commonwealth Government.)

III. DRIED FRUITS.

1. *Currants*, 185,173cwts. (160,356cwts.); increase, 24,817cwts., exceeding previous record of 164,145cwts. in 1928-29 by 21,028cwts.

2. *Raisins.*—Sultanas, 212,514cwts. (195,119cwts.); increase 17,395cwts., established a record, the previous best being 200,872cwts. in 1932-33. Other raisins, 32,165cwts. (54,484cwts.); decrease, 22,319cwts.

3. *Other Dried Fruits.*—Apricots, 20,095cwts. (20,623cwts.); plums and prunes, 11,423cwts. (8,286cwts.); peaches, pears, apples, &c., 9,361cwts. (12,341cwts.).

IV. MISCELLANEOUS.

Market gardens, 1,994 acres (2,105 acres). Pumpkins and melons, 308 acres (310 acres); 1,767 tons (1,819 tons). Tomatoes, 566 acres (485 acres); 184,067bush. (170,292bush.). Potatoes, 4,664 acres (5,824 acres); 19,377 tons (19,501 tons). Onions, 397 acres (417 acres); 2,993 tons (3,008 tons). Other root crops, 578 acres (584 acres); 3,244 tons (3,216 tons). Nurseries, 165 acres (168 acres).

V. OVERSEA EXPORTS.

The value of the total oversea exports of the products of vineyards and orchards for the year 1934-35 was £1,523,371 (£1,772,080); decrease, £248,709, the principal items being dried fruits, £656,944 (£822,782); wine, £731,081 (£702,392); apples, £85,269 (£183,732). Complete details of interstate exports are not available, but annually about £600,000 of wine and brandy are exported to the other States.

EGGS IN SHELL AND EGG PULP EXPORTS.

The grand total exports for each of the years 1930-31 to 1934-35 were, respectively, £156,632, £236,095, £342,915, £358,056, and £360,540. For the last year, 1934-35, exports constituted a record, and showed an increase of £2,484 over the previous year, 1933-34, and £203,908 over the year 1930-31.

The grand total exports of eggs in shell and in pulp in terms of eggs in shell is estimated to have been 3,000,000doz. for 1930-31, 5,200,000doz. for 1931-32, 7,300,000doz. for 1932-33, 7,900,000doz. for 1933-34, and 8,000,000doz. for 1934-35.

Compared with the previous year there was an increase export of 246,332doz. eggs in shell to overseas countries and of 38,150doz. to the other States. There were decreases of 121,000lbs. of egg pulp exported to overseas countries and 116,031lbs. to the other States. Practically the whole of the eggs in shell and in pulp to oversea countries is shipped to the United Kingdom, while New South Wales and Victoria are the heaviest buyers amongst the States of the Commonwealth.

The following are the details for 1934-35 and 1933-34:—

State.	Eggs in Shell.		Egg Pulp.		Total Value.
	Doz.	£	Lbs.	£	£
New South Wales (ex B.H.)	790,699	30,473	1,163,619	39,521	69,994
Broken Hill	287,943	12,805	16,938	497	13,302
Victoria	108,837	3,723	1,305,010	38,343	42,066
Western Australia	229,461	12,600	59,384	1,860	14,460
Other States	4,860	233	112,536	3,726	3,959
Total interstate 1934-35	1,421,800	59,834	2,657,487	83,947	143,781
1933-34	1,383,650	56,152	2,773,518	76,558	132,710
Overseas (direct) 1934-35	4,429,318	214,141	83,000	2,618	216,759
1933-34	4,182,986	219,721	204,000	5,625	225,346
Grand total 1934-35	5,851,118	273,975	2,740,487	86,565	360,540
1933-34	5,566,636	275,873	2,977,518	82,183	358,056
Increase	284,482	—1,898	—237,031	4,382	2,484

PAPERS READ AT CONFERENCES.

MURRAY LANDS WEST BRANCHES, ALAWOONA, 1st OCTOBER, 1935.

SILAGE AND SIDELINES.

[G. ANGUS THOMSON (Alawoona).]

Mallee farmers will be subject to considerable anxiety at frequent intervals because of the Mallee's contrary climatic conditions.

If Mallee farmers are to run more sheep, the conservation of fodder is necessary, so that the sheep may not suffer in long dry spells. When wheat and sheep fail, one strives to eke out a living from sidelines. Chaff or cocky-chaff and grain are not the best foodstuffs to make for better products from cows.

Silage is suggested as a conserved fodder (not that hay is not to be considered). There are two practical ways of making silage in these districts, either by stacking or by placing in a pit; 25 yards long, 6 yards wide and 6 feet deep. The ends are sloped to permit the driving of a light trolley right through it, thus consolidating the greenstuff as it is placed in the pit. It is filled several layers above the excavation, and then when it has subsided sufficiently, it is covered with earth to the depth of 2 or 3 feet. When the pit is being constructed the earth from the excavation is placed along the two sides of the pit, and is thus handy for covering when filled with a scoop. Cutting the crop green does not take so much out of the soil as the growing of matured wheats, or other cereals grown for hay.

Wheat grows the best of other cereals in the Mallee areas. Therefore, probably a Macaroni wheat would be the best to plant for silage, or perhaps Rye.

A Macaroni wheat is suggested because of its hardiness and virile growth. The purpose of making ensilage is to preserve as much as possible of the properties of greenfeed.

If the process is carried out by stacking, the stack must be well weighted, to compress the material and thus exclude air as much as possible. The Department of Agriculture can provide literature which deals with the technical details comprehensively. Silage will keep for a good many years, and should the Mallee experience at any time phenomenal years, it would be wise for settlers to lay up a store for the lean years that might come. Hay will not keep for long and its properties decline more readily than ensilage. Ensilage makes for more and better milk and butter. When there is no green picking to be had this naturally reacts favourably on pig production. It would pay if more attention were given to the poultry on many holdings. Quite a few people are able to boast of a few more coins in their pockets than the other fellows because they have given more care to their fowls. A Lucerne patch should be established by the homestead to augment the barnyard diet, and then eggs worth grading may be produced.

CHANGED ECONOMIC VALUE OF MALLEE LAND.

[T. BRUCE FLINT (Alawoona).]

At present and during the past few years, there has been much adverse criticism of the Mallee. Its economic value to the farmers, and to the State has been questioned and one must admit much of the criticism is justified.

The financial position of the farmer is nothing less than deplorable; the state of his plant is almost as bad. There are few portions of the earth which have not some economic value. The first essential is to discover the true economic value, and the second to discover if it is likely to be profitable to develop this.

Agriculturally speaking, rainfall is the principal factor as to the value of any land. In Australia there are thousands of square miles of country with a precipitation of under 6 inches. This country has, and still is producing great wealth, and where it has failed, much of the failure can be traced to faults such as overstocking.

If country of such low rainfall as this is producing wealth, surely the Mallee land—the worst of which has an annual precipitation of between 10 inches and 12 inches—can produce something more than the annual deficits of public and private funds, and the hopelessly despondent attitude so noticeable today among the wheatgrowers of the Mallee. The trouble can be traced not so much to the failure to find the true economic value of the Mallee, as to the failure to realise that the value now lies in a different direction. The mere fact that it has at least two values should prove it is not the valueless country so many people like to assert. Until 1916, the only economic value the Mallee had was wheat growing. The financial position of farmers generally and the improved state of the farms prove it was a true value up to that time. That is no longer the case, and the present difficulties are largely the fault of farmers, Banks and Boards to realise that the economic value has altered. Wheat growing, owing to low prices and high costs, is no longer profitable, and it remains for those who have to live in the Mallee to discover and exploit the changed conditions. Wheat growing should now take its proper position—that of a sideline—at least until such time as prices improve considerably.

At the moment sheep appear the only profitable way of working the Mallee—either wool or lambs, or both. Unfortunately, the limited size of the holdings prevents sufficient numbers being carried to provide a decent income without overstocking. The change-over cannot be successful unless farmers, Banks, and Governments all do their share. The farmer's share is to forget the past and realise that the Mallee must for some years, at any rate, be treated as a grazing proposition, and to plan his farming operations with the one aim of carrying as many sheep as is consistent with safety.

The Bank's work is to provide finance for the change-over. The Government's is for legislation to reduce rents to the level of grazing leases, and to increase the size of the holdings to those who are most likely to make a success of the change-over.

Fodder Conservation.

On the single farm, the aim must always be to conserve fodder and improve pastures. Conservation of fodder should comprise the maximum of hay, oats, and ensilage. If fallow is sown to oats, there should be no difficulty in a normal season of cutting one ton per acre of hay, and the material for ensilage can be obtained by beginning the cutting season somewhat earlier.

Most of my land is now sown to Wimmera Rye Grass, and it is proving a profitable investment. The Department of Agriculture advocates various other grazing plants, such as Lucerne, Evening Primrose, etc. The policy should be, to fallow well 300 acres, and sow to oats and perhaps barley and rye.

Keep fallowing with a plough where necessary and cultivator where possible. All that is necessary is to break up the ground. This will promote the growth of the Wimmera Rye Grass, provide fair feed during the winter, and leave the soil in a condition suitable for the sowing of oats to be used for grazing. If all land on the farm is treated in this way every 4 years, the maximum grazing will be obtained. This can be considerably improved by further subdivision and by growing Lucerne.

Suitable as is this method of work, the average holding is not large enough to provide a decent living by grazing. It is necessary to have about 3,000 acres, all of which will, in due conrse be sown with super and cereals for grazing. The difficulty of increasing the size of the holdings is realised, but for general principles it is better to have one prosperous farmer than three impecunious ones. It is a matter for the Government and the Banks to arrange, but in doing so it must be borne in mind that the transition from wheat growing to grazing must also include reduction in rent. Charges which were always high even for wheat growing, will be impossible under grazing conditions. The farmers have lost, and as soon as Banks and Governments are prepared to realise they also must lose something, conditions will improve. Most farmers realise that the reduced yields are not all due to the lack of rain. The fertility of the soil has been reduced by too much wheat growing and too little grazing.

If the methods indicated be carried on for the remaining period of low prices, the fertility of the soil will have been restored. Should wheat prices by then be more remunerative, the farmer can revert to the production of cereals. With the increased size of holdings, there should be no difficulty in the future of maintaining soil fertility, providing adequate dressings of super are applied both to the crops for grass and grazing.

EYRE'S PENINSULA (EASTERN), AT YEELANNA, 16th OCTOBER, 1935.

PREPARING BEESWAX FOR COMB FOUNDATIONS.

[R. Schultz, Koppio.]

Wax is sweated by the bees into tiny bits like scurf, then kneaded into combs or whatever is needed by the bees. It is said that the bees eat 20lbs. of honey to sweat 1lb. of wax. To prepare wax from the capping knife to the mill first keep it clean. Put the cappings into clean vessels. Keep all weather away from it, especially rain. When the honey season is over, melt up the wax, add a little water and melt in a vat of water. When the wax is melted dip off and strain into a receiver which will hold the lot which is melted. Cover up and allow to cool slowly. Cooling may take three days. It will then be ready for the mill, and it will be prime wax. If the wax is melted a number of times to get it clean, it loses its texture and is poor stuff for comb foundation. Dirty black wax can be cleaned with vinegar or sulphuric acid, but it is a poor product. A lot of wax is used in the Telegraph Department, and wax cleaned in this way is useless for this job as the acid interferes with electricity. Dark wax can be used in many ways; added to a little turps it makes a good floor polish. Wax, lamp black, and turps mixed properly make a splendid boot or harness polish. Many housewives use beeswax to polish their irons; they maintain that it keeps the iron clean and makes it work more smoothly.

CAN A PROFIT OVER EXPENDITURE BE OBTAINED IN GROWING FEED, ESPECIALLY FOR THE PRODUCTION OF WOOL WITH THE PRICE AT 1s. PER LB?

[J. Carter, Koppio.]

There are two aspects to this query, the storing of fodder for use during times of extreme scarcity, when it would be folly to let sheep seriously decline in condition, and the supplementing of natural pastures, even when quite good. It is to the latter aspect that my query is directed. Assuming, for the sake of demonstration, that a farm would carry ½ sheep to the acre on the area available for grazing reasonably well, on a fair average season, cutting, say 10lbs. of wool per head, what increase in production could be obtained by growing fodder crops, or by top-dressing the natural pasture for them?

"Keeping sheep reasonably well", I would define as keeping them only in such condition that no break appeared in the wool. The increase in production could be in either one of two ways—more wool on the same number of sheep, or approximately the same amount of wool per head on an increased number of sheep—the latter way, in my opinion, being the more practicable.

My experience has been that top-dressing the natural pastures with 90lbs. of super per acre, will increase the quantity of food by 50 per cent. from the first application as well as improving the quality of it. Assuming that the 50 per cent. increase in feed, produced a like increase in wool, and with judicious management (it is a reasonable inference that it would), there would be a loss incurred on the undertaking. With super at £4 10s. a ton on the farm, a 90lb. dressing would cost 3s. 9d. per acre, and a 50 per cent. increase in wool on the ½ sheep cutting 10lbs. would be worth 2s. 3d., thus showing a loss of 1s. 6d. per acre.

On better grazing land, however, the result would be considerably better. Where the untreated natural pasture will carry one sheep to the acre, the 50 per cent. increase due to top-dressing would show a profit of 9d. per acre, and to carry the comparison still further, two sheep to the acre country would sow a profit of 5s. 3d. per acre. Probably one sheep to the acre would represent the carrying capacity of the greater area worked by members of this branch, and for that reason, I am taking that as standard. To obtain a profit of 9d. per acre for the carting and spreading of the super, does not impress me as being a remunerative return for the money and labour expended. An alternative to the top-dressing would be to crop 75 acres, preferably in two or more paddocks, with oats, or barley or both which would cost just the same as top-dressing 250 acres of grass, made up as follows:—

Ploughing at 5s. per acre	£18 15s. 0d.
Combining at 2s. per acre	7 10s. 0d.
1 bushel seed at 1s. 9d.	6 11s. 3d.
90lbs. super	14 1s. 3d.
Total	£46 17s. 6d.

The crop could be grazed in rotation with the grass paddocks until about the middle of September, and then left to mature, and used in the autumn when the supply of food was least plentiful. The disadvantage of the cropping, as compared with the top-dressing, would be in the later start in coming into use, but this could be largely overcome by fallowing the required area, and thus being able to get the crop started with the first good rain.

Probably one working, a cultivation in the spring time, would be the only extra one required, and at 2s. per acre that would reduce the area cropped, for the same expenditure, to 70 acres.

Whether the benefit from the cropping alternative would equal that from the top-dressing is for your consideration, and probably a combination of the two would be more nearly ideal.

TREE CULTURE ON THE FARM.

[J. H. VIGAR, Mount Hope.]

With few exceptions, our country districts are lacking in ornamental trees. The word ornamental embraces all trees which are likely to grow in our country districts. Many of our best trees are palatable to stock and rabbits, protecting them with a good fence and netting is money and labour wisely spent. Farmers in the wheat belt should be more alive to the advantages of tree culture, as districts above the 20 inch rainfall average, are generally better off in the way of beautiful trees, natural to their locality, so the lack of tree culture there, is not so noticeable. In our lower rainfall districts, many of the farmers are too drastic in the destruction of timber such as the mallee and native pine. More forethought should be used, thus preventing drift, a menace which is causing ruin to a vast area of this State.

Our noble redgum will have pride of place in wheat belt districts. This tree, though not generally reckoned to be a native of many districts, will do reasonably well in many more localities than is generally supposed. You will have noticed that the red gum is to be found growing practically all over Australia, in what one may term favoured positions, such as along water courses, edges of swamps, or in some low-lying place, where water has lodged at some time. The reason why the redgum is growing in these seemingly favoured positions is that a certain temperature is required to germinate the seed, and the young trees have started to grow from seed at the water's edge, in October, and have become established in favoured positions. It will do well in many more localities, other than its natural haunt. Where the redgum does not find conditions favourable, the sugar gum will often do fairly well. It is a native of this State, and I believe the Southern Flinders Range is its natural haunt. Some very fine specimens are to be seen in the Melrose district. The sugar gum is a very popular tree, and I venture to say it has taken pride of place in tree culture by the farming community, but it should not be planted in districts where the redgum would do as well. The Tuart gum of Western Australia is doing much to beautify many districts where no other variety of gum tree will thrive, such as our exposed coastal districts of a limestone nature and low rainfall. Livestock and rabbits are very fond of it, so it must be protected. The native pine should receive more attention, and will do well all through the wheat belt, and outside of "Goyder's line." Although young trees of this variety are not supplied by the Woods and Forests Department they are often easily raised from seed, where the parent tree is protected. As a rule they transplant successfully, if moved when young. Huge areas of this valuable timber tree have been destroyed in this State, and nothing is being done to replace it. The native pine will grow where the imported pine will die; therefore many of our districts with a low rainfall should be beautified by its culture. Most of the imported pines appear to do better in the higher rainfall districts, but the Norfolk Island pine is a good tree for many localities where the others will not thrive, and will do well in exposed coastal situations of a limestone nature. The sheoak is a tree which is quickly dying out, and more should be done to fence off certain areas to preserve it. The tree comes naturally from seed if protected, is a valuable fodder, and the continuance of its growth should be practised. Although not generally reckoned among the ornamental trees, the almond should be always given attention when tree planting is in progress. I have yet to find

the district in the wheat belt where this tree is not growing. All over the State it bears evidence of early settlement, it is a beautiful tree, and revenue-bearing. Therefore it should never be neglected. The Carob tree, although not much noticed, is a hardy tree, and some good specimens are to be seen in the northern areas, and also on the West Coast. There are many other imported trees which are hardy and will thrive in varied localities. The wild peach is a very valuable fruit tree, and will thrive in all districts under the 18in. rainfall. Just where my own homestead is situated, fruit trees will not grow successfully, other than the fig tree, and grape vines, the latter being in sheltered positions, but I have some very fine specimens of the wild peach growing from seed in a plantation of sheoaks, native pine, and Tuart gums. Much improvement of the fruit could be attained by selection, and I would like to see our fruit experts give attention to this tree with that object in view. The average person does not see much sense in doing work if he is not likely to receive monetary advantage. In all districts there are odd people who take a pleasure in beautifying their homesteads by planting trees. I want to see many others moved with the same incentive, and not to confine operations to the homesteads, but to extend to the paddocks and public roads. In conclusion, let us take warning of the drift menace in our own State and other parts of the world. The United States of America is having a bitter experience of thoughtlessness, and a high tree planting drive is in progress. Natural conditions had been destroyed, and nothing was done to replace them by better conditions. Let us take warning.

(Mr. Vigar suggested that, as a Centenary gesture, a meeting of each Bureau in every year be set aside for a discussion on tree culture. A resolution to that effect was passed at the recent Congress.)

THE PROBLEM OF SOIL EROSION.

[A. DOLEY (Yeelanna)]

This subject has been given considerable publicity, but it is of such importance that further discussion should be of value. Not only in this country is soil erosion being experienced but it is assuming alarming dimensions in Africa and the United States. In the United States, it is reported that 25,000,000 acres have become useless, and in Africa that the Sahara Desert has advanced 150 miles on a 700 mile front during only three centuries. Destruction of the natural timbers and herbage leads to erosion, whether it is in an area of high rainfall or low. In a high rainfall area, generally associated with hilly or mountainous country, the soil is often washed away, especially if cultivation is carried on extensively. When pasture takes the place of trees, the damage is not so great. But it is in the dry areas that the greatest menace lies in this State. The north east corner of the State can, judging by reports, be classed as desert with shifting sandhills, very little bush, and owing to continuous dry years, little or no grass. There being nothing to bind the soil together, in every wind the soil is being shifted, leaving the ground bare of topsoil and piling up the sand around any obstruction. Even if good rains come a lot of wind-swept ground would grow no feed, as there is no top soil to grow it on or to conserve the moisture. This desert tends to become larger, with every wind storm blowing the sand further onward covering fertile ground and destroying vegetation. The problem of staying the course of the sand in these areas has become a national one, and could probably best be done by re-afforestation on a large scale in the fringe country which has not yet been so spoilt by sand that it will not grow anything, even if a few good years were experienced. The prevention of further destruction of trees and bush in this fringe country rests with the individual at present, though just recently a deputation was received at Parliament seeking assistance in this regard. Assistance would also be necessary in keeping the rabbit pest down. Farmers in the drier portions of the State are up against the same problem, though on a smaller scale. Clearing the mallee has led to continuous cropping to kill the shoots. These methods have been carried on past the pioneering stage, and have made the soils more sterile and liable to shift. By keeping the ground covered with grasses, fodder crops, and leaving the stubble, and restricting the amount sown to wheat with its bare fallow period the trouble could be greatly lessened. By this means more stock could be carried and the soil would be improved; this in itself would lessen the tendency to drift. Belts of timber left or planted near the portions likely to drift will greatly assist in keeping them stable and also serve a useful purpose as shelter for stock, beside relieving the barrenness of the landscape. The question may be summed up as a plea for the tree; where clearing must be done let it be done wisely with a view to the future.

PREPARING LAND FOR SEEDING.

[R. PROCTOR, Yeelanna.]

I will commence my paper with the treatment of stubble land for growing oats and barley. If the stubble is on the light side, burn it early in the burning season, because once a rain falls the straw is spoilt for burning and stock also ruin light straw if allowed to run in it too long. If the stubble is fairly dense it is not necessary to burn until the end of February or the beginning of March; then it pays to burn and have the land free from straw so that if a good rain falls the land is ready for working. Immediately the straw has been burnt, harrow the land whether the conditions are wet or dry, so that the ashes are preserved instead of being allowed to blow away. By harrowing the stubble land early, the weeds are given a good chance to come up with the early rains, then the land should be cultivated with a stump jump cultivator, or if the land is of a loose nature, it can be done quite successfully with a spring tooth implement. After this working the land is ready for sowing oats, but for barley I think it pays to work it over again during the month of June with a spring tooth implement, and if the land is free from weeds the barley can be sown with a combine with harrows attached.

In regard to the working of fallow land a great deal depends on the weather conditions. If rain falls in February or beginning of March, I like to harrow with a good heavy set of harrows, working in the opposite direction to the previous cultivation, so that all ridges are levelled off; then the cultipacker should be brought into use. A light built packer will be found a great advantage with bags of sand on the packer to give greater pressure on the under layers of soil, but if the land is of a sandy nature it is impossible to work a packer with heavy weight on, as it has a tendency to push the sand ahead. I am a great believer in the use of a packer, especially in heavy soils that have a loose nature. This implements breaks down all the clods and firms the seedbed considerably. By having the fallow well packed, all weeds germinate much more rapidly than on fallow that is left in its rough state, and a good germination of weeds with the early rains is one of the main reasons for a good healthy, clean crop of wheat, because weeds started in April are much more easily destroyed while the day temperatures are fairly high than they are in the early winter months. Not only does the packer give a good germination of weeds, but it also gives a far better germination of wheat when sown. If the fallow is carrying a lot of big clods when seeding time arrives, a patchy germination is often the result, particularly if the opening rains are on the light side. Therefore the cultipacker is an implement that is due for much greater credit than it receives, and no farmer should be without this implement. After the land has been packed and further rain falls, the land should be harrowed again or a light working with a spring tooth cultivator or combine given; this working to cut all the small weeds. It is very important to have all the tines of the cultivator set as near as possible to the same depth, and never use a spring tooth with some tines with new shares on and some with shares half worn out. Have all new shares or all partly worn, because uneven shares always leave an uneven seedbed.

Grassland has proved quite a success in this district for growing wheat or barley and is perhaps the most efficient way of producing these two cereals. When preparing this land, I always like to get a good grass fire over the paddock, or if a fire is impossible, the land should be stocked very heavily so that any grass is cleared away as much as possible. When the first rain falls after harvest get some of the ploughing done; time for this work can be found while waiting for weeds to get a start on the fallow On land that has had a good grass fire over it I prefer the mouldboard plough for this work which should be done as shallow as possible, but the plough must be set for narrow cutting, so that a thorough job can be done. If, on the other hand, the land is carrying quite a coat of dry grass, I prefer the cultivator for breaking up grassland, as this implement leaves the rubbish on top of the soil instead of turning it under as a plough always does. My reason for leaving the grass on the surface is because the land packs down a lot better. When a lot of grass is turned under it has a tendency to keep the soil too open and the results are often a badly affected crop with take-all. When a cultivator is used for this purpose it must be equipped with a set of narrow shares, otherwise great difficulty will be experienced in keeping the furrows down. After the land has been broken up, I usually harrow with heavy harrows, working across the ploughing as much as possible; then in the case of another rain the land should again be cultivated with a stump jump cultivator, this time using a wider share. Immediately after this cultivation the land should be packed down so that any weeds, such as charlock, poppies, or clover that have not already germinated, will be given a better chance to start before the crop is sown. After the packing has been completed it may be an advantage to harrow again, or if the weeds are still making an appearance, a working over with a spring tooth implement will be found quite a payable proposition. After these workings, the land is, or should be, in good condition for seeding. You will see that this land receives a good deal of working, but it is still far below the cost of fallow prepared land, besides an extra year's feed can be obtained from this land, which will more than compensate for the difference in yield between grassland and fallow. Some people just plough up grass land, then combine it in, but I maintain that a few extra workings make the difference between a good and poor crop. No doubt some people will think that my preparations of land for seeding seem almost impossible, but all this work can be accomplished if a good, strong plant is on hand and plenty of power used for hauling the implements. I find that 400 acres farmed in the manner that I have tried to explain are much better than 600 acres farmed poorly.

EYRE'S PENINSULA (EASTERN). at BUTLER, 8th OCTOBER, 1935.

FAT LAMBS ON EYRE'S PENINSULA.

[E. J. BARRAUD, Lipson.]

The fat lamb industry is rapidly becoming of great importance in this part of the State. Those people who placed their money in the Port Lincoln Freezing Works and thought they had lost it are now realising that it is one of their best investments. Building palatial offices in the city is not evidence of prosperity, for a primary producing country's real wealth is in the volume and value of its exports. Lamb raising for the overseas market is one of our principal sources of wealth, and for that reason we should enter the business on sound lines. The past two or three years have been fairly good grazing seasons, except for the grasshopper plague. However, seasons will not always be favourable, and the fact that so little provision is being made to conserve fodder is causing some concern to those who are looking forward to great expansion in this industry. Many farmers on Eyre's Peninsula have had very little experience with sheep and lambs, as they are just changing from wheat growing to mixed farming, and a word in season may not be out of place.

Sowing catch crops for ewes and lambs is quite the right thing, but it is not sufficient. In a very late season, or a very dry one, sown crops make little, if any, growth. Besides providing green feed, provision should be made for hand-feeding when necessary. Climate and conditions vary on the Peninsula, and methods to be adopted for hand-feeding may be different. The writer's experience, however, leads to the opinion that lamb raisers of, say, 200 or 300 fat lambs should have at least 50 tons of hay and 500 or 600 bushels of oats in reserve for their sheep. There will be seasons when it will not be needed, but that should not cause any worry; it will be there when required.

Hand Feeding.—The plan should be to cut wheaten hay when in bloom, before the grain forms, and get it into the stack as soon as sufficiently dry. The hay, being green and without grain, will not be troubled by mice. In feeding the sheep, the hay should be chaffed and mixed with oats. Ewes with lambs should maintain their condition on 1½lbs. of chaff and 1lb. of oats daily if the sheep have the run of a stubble paddock. It is not advisable to feed grain to ewes before lambing, unless in low condition, because there is a risk of their becoming too fat. Self-feeders are not favoured because they allow the strong sheep, which need feed least, to get the most. A good plan is to feed in boxes; quite a small box will feed 4 sheep. A good feeder can be made by putting two posts in the ground at each end of a bag trough. About 12in. apart, drive stakes into the ground every 4 or 5ft., the same distance apart as the end posts, and bore holes in the posts and stakes about 14in. above the ground. Strain a wire on each side, open cornsacks the long way, and stitch the bag to the wire, leaving a bag trough between the stakes. It is necessary to put a weight in the trough to prevent the wind destroying the bagging. Water pipes are best for the purpose. Boxes, however, are easily moved, and will last for years, if taken care of.

Foxes.—If foxes are troublesome, and ewes and lambs are not yarded, it is well to feed just before nightfall. Ewes will camp with their lambs the greater part of the night after a feed. Foxes get the lambs when the mothers leave them some distance in search of food. If you yard the sheep, make a fairly large enclosure in a sheltered spot; one height of netting is sufficient. Foxes are very timid, and will not venture into a yard when sheep are there.

Suitable Rams.—If Eyre's Peninsula is to become a big lamb export centre, more crossbred lambs should be produced. A difficulty facing farmers, especially in the newer districts, is the ram. Too few are usually mated with the ewes, and in consequence the lambs are dropped over too long a period. A ram should be used for every 40 ewes in the flock. What is to be done with the rams after the mating season is the problem. The best solution seems to be for at least one farmer in each district to have a stud of one British breed, and hire rams to his neighbours. Opinions differ as to the best cross for the market, but in considering this question the district has to be taken into account. The short wool breeds do remarkably well in the warmer and drier districts, while the longwools appear to be best in colder and poorer localities. The exporter is looking for the short-legged, fine-boned, thick-bodied lamb, with bloom and sap, and will pay to get what he wants.

A very bad season with very little reserve fodder for the flocks would give this growing enterprise a set-back that might be felt for years. If you must gamble, do it on the sale of your produce, but do not gamble on the seasons.

FODDER CONSERVATION ON THE FARM.

[C. F. Jericho, Butler.]

For the past four to five years Eyre's Peninsula has been very fortunate in early rains for feed, and the increase in the stock-carrying capacity of the land has been wonderful. Settlers, however, are facing a great danger, that of overstocking. On most farms it is surprising to note how little hay or other feed is set aside to carry the stock over a late or poor season. It should be the aim of every farmer who manages his holding as a mixed farming proposition to make adequate provision for future years. It is difficult, of course, to know in just what form to conserve fodder. If much hay is cut, mice are the chief trouble, and in a few years the stack will be destroyed. Much could be done by storing oats in silos made of galvanised iron; 5ft. 8in. sheets could form the circular part of the silo and if made 5 or 6 sheets high it would store 350 to 400 bags of loose oats. Mice could not damage the grain, and if put in dry and clean, it would keep for many years.

In good years a lot of growth on the farm could be conserved into ensilage. Providing it is done in the right way, this fodder will keep for years without any damage by vermin and it is necessary if Eyre's Peninsula farmers are to make a proper success of fat lambs. For feeding sheep through a dry spell hay seems to be the best. Cut Early Burt oats for hay on the green side, and if carted into the paddock there will be hardly any waste. Farmers are warned not to overstock, and to make proper provision to tide the stock over bad seasons and those years when the opening rains are late.

SOME SUGGESTIONS FOR THE EYRE'S PENINSULA FARMER.

[Frank Masters, Verran.]

Under conditions pertaining to developing a scrub farm one is forced to continue growing wheat, at least to a certain extent, for several reasons, the greatest being the need of preserving stock, plant, and machinery that cannot be very well scrapped. Then too, wheat dovetails in with livestock husbandry for feeding purposes. Also, unless the land is cropped with some cereal, shoots will again take possession and the whole previous labour is wasted. Wheat generally seems to fill the bill. Even when the shoots have been all killed, the land goes back until the grazing becomes very scanty unless cropped and manured. The aim should be to grow the heaviest crops possible. Early fallow, worked and kept clean with sheep and sown to suitable varieties of wheat for the district and of good milling quality should give best results. It is necessary to test different varieties from time to time from breeders of repute. Wheat selections are being made at Roseworthy College with a view to increasing the yielding qualities of good flour wheats, in order that demand for our wheat overseas is maintained and if possible stimulated. Such wheats as Gallipoli, Nabawa and Waratah must be discarded to achieve this end. When one comes to consider the average for County Jervois for the past four seasons, (only 7.66bush. per acre) it is evident that general farming methods need review in an endeavour to increase our returns. Taking similar type country and rainfall on the other side of the Gulf, in County Daly, we find an average for the same period of 14.91bush. per acre, and until we approximate that average here we should not rest content. Their average is obtained by intensive farming, ours by extensive, and it would pay us better to limit the area and give it greater care and attention. This would mean cropping with wheat infrequently, and growing fodder crops for grazing and rotational cropping with oats and barley. Thus the farm would become a mixed farming proposition with improved results financially. This is possible throughout this country now that water reticulation is fairly general. Sheep for wool and fat lamb raising, cows of good dairy strain, pigs of right type, and poultry raising should be our aim. Expenditure on fencing is of course necessary, and the greater the number of paddocks on the farm, the better the rotational grazing of both natural pasture and sown. Once the fencing has been done the aim should be to carry the largest number of stock consistent with carrying them well, thus getting the most from the fencing. The number of stock a farm can carry is usually governed by what it is possible to carry through the dry and lean period of the year. Here is one of our weak points, but it can be remedied by the growing of oats, barley, rye, lucerne, and Wimmera grass and the making of some of them into hay and silage, and hand-feeding as required and grazing the rest. Thus the number could be increased probably 50 per cent. or even more, and the revenue likewise. Certainly a little more labour would be necessary, but that item is to-day reasonable and would assist the unemployed problem. Quantity is not the only consideration, but attention must be paid to the quality of the stock, remembering that second-rate stock eat as much as the best, and the better the quality the better the returns. I would suggest buying the best the pocket will permit and improving it as the opportunity occurs. Taking Merino sheep for instance, it is wiser to buy from stations where breeding for wool (and frame to get more wool) is a specialty, than to attempt breeding for oneself, especially in view of the fact that fat lambs are worth more than grown sheep off shears. The wool will be all right, of even type, the frame all right for breeding fat lambs, and two fat lambs will be raised in the time it takes to raise a sheep. Also the lamb is grown during the winter months, when feed is usually abundant, and goes off the mother before the feed becomes dry and scarce. This in itself means more ewes can be carried, especially if care has been taken to put by stocks of fodder to ensure their welfare until the green feed comes again. The early lamb is the more profitable and Roseworthy experiments have shown that should green fodder be absent in March, April and May, early lambs can be grown satisfactorily on silage and some grain such as oats or barley. As to rams, whilst most British breeds are suitable, I prefer the Border Leicester, as should anything untoward happen and lambs be left on hand, that setback would be nullified by having the ewe lambs next year as ideal crossbred mothers, and the foundation laid for the highest type of lamb if they are then mated to Southdown rams.

The crossbred ewe would also have a fairly valuable fleece, which is not the case with most of the British breeds except the English and Border Leicester, and Ryeland breeds. Likewise, with cattle, the best should be kept. Decide upon the breed and buy the best possible. Weigh all milk night and morning and test the cows for butterfat, say, every three months. I have discovered, by this means, that even from the same parents differing strains in regard to production are discovered, thus giving one the opportunity to discard the lower and breed from the higher and build up the production of the herd. It pays to feed for production when cows respond, otherwise the food is wasted.

Pigs should have their place in the farm economy, thus converting waste offal, milk, etc., into a marketable commodity. Indeed, much of our wheat could profitably be fed to these animals, as 4lbs. of wheat are calculated to produce 1lb. pork; the former at say, 2d. and pork at 4d. show what might be done, and is being done at the present time by many who devote the necessary attention to pig raising. Green feed paddocks with self-feeders give the best results, and failing green feed meat-meal would assist in giving the diet the necessary balance. Poultry needs are in egg-production powers, and the foundation stock should be of good laying strain of whatever breed is chosen. White leghorns seem to fill this bill nearest, although some strains are better than others.

To-day the farmer has more definite selection at his disposal through breeders' societies of sheep and pigs, herd testing by the Agricultural Department, and egg-laying competitions at Parafield and elsewhere under strict supervision, so that there can be little excuse for not increasing the productive value of all livestock by judicious selection. Also, crop competitions indicate values of different varieties of wheats.

These are various directions in which increased returns can be expected. In the management of rotational grazing of paddocks the health and constitution of the stock can be improved. All pasture should be handled to keep it short. The sowing of cereals early with the first rains to ensure sufficient feed must be undertaken. Rye in this connection can be highly recommended as giving twice the amount of feed of any other cereal in the same time. It needs grazing heavily to get the best from it, as it is notably hard in straw, when it becomes stalky. Barley is highly palatable in the green stage, and, as grain, should give higher returns than wheat. Oats for grazing and hay have their place, especially the earlier varieties, which mature sufficiently early to allow them to be got out of the way or into stack before the wheat is ripe.

[*Papers Read at Conferences.*]

THE ADVANTAGES OF CROP COMPETITIONS.

[N. G. STEWART, Butler.]

As South Australia is solely dependent on production and the growing of grain as the main source of revenue, the time has arisen when the members of the Agricultural Bureau must look for some method of improving the yield and producing a quality of grain high in commercial value. By district Crop Competitions and co operation of producers, much benefit could be attained. To win a Competition the farmer has to produce a crop that at the time of judging by an officer of the Department of Agriculture has the promise of a good yield, is true to type, free from weeds and foreign matter, and diseases that are under his control, such as take all, smut, bunt, &c. For this purpose the opportunity is now available to obtain seed true to type from the Roseworthy College, or from the Experimental Farms and plots conducted under the supervision of the Department, and by careful rotational cropping and suitable methods each producer can compete.

Critics tell us that it is not a paying proposition to work and prepare for seeding the whole of the land cropped in the same manner as the Competition plot. In my opinion, results speak for themselves, for in the majority of districts where plots are conducted the yield from these plots is much higher than the district average and should be an incentive to work and seed only the acreage that could be done thoroughly, and not try and prepare more than what the plant can manage in proper seasonable time.

Through such channels as the Competitions we would build up a better standard of commercial grain, as in many instances varieties of low milling quality are disallowed for competition; and wheat from Competitions is always keenly sought after for seed for the following crop.. They also strengthen the membership of the local Branches of the Bureau as they create social interest in the district, because each competitor follows the progress of other entries and methods, and in most cases a District Inspection is organised, when each entry is inspected and its methods of cultivation, varieties used, and the estimated yield fully discussed. From all these point much practical knowledge is obtained.

NON-IRRIGATED FRUIT GROWERS' CONFERENCE, LYNDOCH, 5th NOVEMBER.

FERTILISING ORCHARDS AND VINEYARDS.

[B. BOEHM, Light's Pass.]

The practice of manuring has not kept abreast of the other branches of horticulture, such as spraying, pruning, &c. In the fifteenth century the value of marl, chalk, ashes, soot, blood, and decayed corn, &c., were recognised as a manure, yet to-day it cannot be said that the application of a certain quantity of a certain kind of fertiliser will give a certain increase of fruit. The wheat grower knows for certain that if he applies a quantity of superphosphate he will receive a certain increase in yield. Likewise, the pastoralist knows that if he topdresses his land he will be able to grow heavier and better pastures.

In fruit and vine growing, however, one can only point to isolated instances where the application of manures has proved of benefit. The Berri Orchard has proved that under irrigation an application of 5cwts. of sulphate of ammonia to citrus trees has been very profitable. Under irrigation practices manuring is much more general than in non-irrigated land. In some instances up to a half a ton of fertiliser is applied per acre.

Mr. H. N. Wicks, in a paper, "The Problem of the Off Year in Apple Cultivation," has proved that an application of sulphate of ammonia has been of benefit to apple trees. On the other hand, an experiment conducted on Messrs. Plush's property at Light's Pass, an application of superphosphate actually decreased the yield of apricots, yet applied in conjunction with sulphate of ammonia resulted in an increase of about ½bush. per tree.

Another experiment in the Barossa district, it is hoped, will prove of benefit to apricot growers. In this soil, sulphate of ammonia and complete manure, as against no manure, are being replicated three times. The test is now in its second year. The result of the first year is very encouraging as regards the last harvest, and also the condition of the trees for this harvest.

Then there is the experience of growers as a whole. Some have not worried about the subject at all, being content to take from the ground as much as it will give, and in return put nothing back, which is a poor policy. Again, others are very enthusiastic about potash, superphosphate, nitrogen, cover crops, &c., but as a result of all this the grower cannot point to anything definite of what to apply, how much, where, or when. To overcome these problems it is hoped that the Department will at some time take the matter up. In the meantime, however, every grower should start to make some simple comparisons himself, such as, say:—

(1) Complete manure against no manure.
(2) Sulphate manure *versus* no manure.
(3) Green manure against bare ground.
(4) Stable manure against no manure.

The average grower could do this by dividing a fairly uniform block of trees or vines growing on apparently the same class of soil, treating half the block with the proposed manure and leaving the other half alone. The grower will soon get interested in his experiment, and after some years—by noting the harvest and the condition of his trees and vines—he should be able to determine a plan of manuring suitable to his particular locality and conditions.

In this proposed comparison phosphoric acid has been omitted because, although it is essential to the cereal grower, it seems fairly safe to say that super applied as a tree or vine food is a failure. There is, however, another use for it; top dress a portion of the garden with, say, 2cwts. of super per acre in early autumn with the object of making the natural grasses grow; these can be ploughed under to increase humus. Sulphate of ammonia could also be tried in a like manner.

GREEN MANURES.

It will possibly be contended that the practice is too risky, and it is admitted that in some years without irrigation it will not be possible to plant the seed early enough, but where the rainfall is 20in. or over, or where irrigation can be applied—even if only on a small scale—the risk of using too much moisture is well worth while, because there are certainly very few, if any, fruitgrowing areas where a supply of humus is not essential.

Superphosphate comes into its own here, too, when the seed is sown a dressing of, say, 2cwts. or 3cwts. per acre will give the crop a good "kick off." The crop must be sown early to obtain the maximum bulk some time before bud burst. The crop should be turned under two or three weeks before bud burst. Late turning under at tree blossoming or after should be accompanied by an application of 1cwt. or 2cwts. of sulphate of ammonia in order to prevent the locking up of available nitrogen by soil bacteria and consequent short supply for the trees, which it is estimated take in about 90 per cent. of their plant food at or prior to bud burst. Lime is also important. In land that has been under cultivation for years the finer particles of lime have probably been baked into the subsoil in heavy ground. Lime also is necessary to improve the texture. Green manuring also tends to bring more acid into the ground, and lime will again be necessary.

There are about a dozen elements essential to plant life, but of these it appears that only four need concern the grower; these are nitrogen, phosphate, potash, and lime. By applying any one of the latter another may automatically become deficient. For instance, there may be a shortage of nitrogen, but as a result of the increased growth due to added nitrogen, there may be insufficient phosphate to maintain this extra growth, and so a phosphate deficiency results. Likewise, if phosphate and nitrogen are applied, these may expose a scarcity of potash.

DEPARTMENT OF AGRICULTURE.

SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

Conducted at Parafield Poultry Station.

LEADING SCORES TO WEEK ENDED 22nd DECEMBER, 1935.

FIRST GRADE EGGS ONLY.

SECTION 1.—WET MASH.

Class 1.—White Leghorns.

	Eggs Laid.	Bird Nos.
Singles—		
E. McKee	188	27
H. C. Stacy	181	36
E. McKee	177	28
J. J. Devlin	177	207
Trios—		
E. McKee	519	28–30

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR Summer, 1936.

EGGS FOR HATCHING AND DAY OLD CHICKENS

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

BLACK ORPINGTONS.

EGGS.—10/- per Setting of 15 Eggs. Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—17/6 per dozen; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30/- per 100.
DAY OLD CHICKENS.—15s. per dozen; £3/10/- in lots of 100.

Free on Rail, Salisbury.

DELIVERY.—CHICKS—January to March.
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2ozs., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

OFFICIAL SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

CONDUCTED AT PARAFIELD POULTRY STATION.

ONLY FIRST GRADE EGGS RECORDED.

SECTION 1.—WET MASH.

Class No. 1.—White Leghorns.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. Anderson, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April to 31st December, 1935.

Feeding Tests commenced on 1st April, 1935.

1. **Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.**
2. **Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.**
3. **Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.**
4. **Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.**
5. **Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.**

	No. Eggs Laid 1st April, 1935, to 30th November, 1935.	No. Eggs Laid Month of December, 1935.	Total Eggs Laid 1st April, 1935, to 31st December, 1935.

No. 5 Test	4,556	496	5,052

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on 2nd January, 1936:—

BUTTER.—The year ended has been more satisfactory to producers than for some time past, as the prices obtained for dairy produce have been better and, with rates for wheat having moved upwards, the position of farmers has been improved. Prices for butter in London touched as low as 63s. per cwt. during the 1934 season, whereas the lowest point reached in 1935 was 70s. per cwt. Production in this State is now steadily declining, but a record tonnage of butter was produced in the aggregate for the season. London rates have moved upwards slightly and at present are 95s. to 96s. per cwt., but there has been no alteration in local prices recently. Choicest creamery fresh butter, in bulk, 1s. 3¼d. per lb.; prints and delivery, extra. (This price is for local sale only and, under the quota system, the equalised price manufacturers will receive will be 1s. $0^{3}/_{32}$d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines, from 10½d. to 11½d. per lb. for choicest; stores, 6d. to 8d. per lb. (These prices are subject to equalisation levies.)

EGGS.—Many of the consignments received during the last few weeks have been weather affected, although there was a strong demand for best quality new laid eggs; off conditioned were not so readily saleable. Present rates are:—Ordinary country eggs, fair average quality, 3d. per doz. net; long distance rail or shipping eggs, lower; selected new laid, clean eggs, full-sized, 7d. to 7½d. per doz. net.

BACON.—After the heavy demand for hams just prior to Christmas there has been a lull in the trade, although the sale of bacon has kept up fairly well throughout, varying according to climatic conditions. Values are:—Best quality sides, 9½d. to 9¾d. per lb.; middles, 9½d. to 10d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 1s. 2½d. to 1s. 3d.; cooked, 1s. 4½d. to 1s. 5½d. per lb; lard, bulk, 5d. to 5½d.; prints, 6d. to 6½d. per lb

ALMONDS.—Stocks held by growers are now very light, and the consignments received during December were not heavy and were all cleared. The new crop will not be available until February and promises to be a moderately good one. Quotations at present are nominally:—Softshells and Brandis, 9d. to 9½d.; hardshells, 5¼d. to 5½d.; kernels, 1s. 10d. to 1s. 10½d. per lb.

HONEY.—Market continues dull with heavy carry-over stocks and the outlook is not very promising. Quotations remain unchanged at:—Prime quality clear extracted, 2¼d. to 2¾d. per lb; lower grades, 1d. to 2d. per lb.

BEESWAX.—Moderate to good trading continued for this commodity and values were without alteration, being 1s. 3d. to 1s. 4d. per lb., according to quality.

LIVE POULTRY.—Auction sales held every Tuesday, Wednesday, Thursday, and Friday at our salerooms, which are in every way the best equipped in the State. As usual during December the catalogues submitted were very heavy, but the greater proportion of the birds consigned were not altogether suitable for table purposes. Fowls of the Leghorn type are rather small for this purpose, but for prime quality, heavyweight stock there was always keen competition. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 4s. to 5s.; nice conditioned cockerels, 3s. to 3s. 11d.; fair conditioned cockerels, 2s. 6d. to 2s. 11d.; chickens, lower; heavyweight hens, 2s. 4d. to 3s. 3d.; medium hens, 1s. 8d. to 2s. 3d.; light hens, 10d. to 1s. 6d.; couple of pens of weedy sorts, lower. Prime young Muscovy drakes, 5s. to 6s.; young Muscovy ducks, 3s. to 4s.; ordinary ducks, 1s. to 2s. 3d.; ducklings, lower. Geese, 2s. 9d. to 4s.; goslings, lower. Turkeys, good to prime condition, 9d. to 1s. per lb. live weight; turkeys, fair condition, 6d. to 8d. per lb. live weight; turkeys, poor and crooked breasted, lower. Pigeons, 3d. to 4½d. each.

POTATOES.—New season's, 7s. per cwt.

ONIONS.—New season's, 7s. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of and to the end of December, 1935, also the average precipitation for December, and the average annual rainfall.

Station.	Dec. 1935.	Av'ge. for Dec.	To end Dec. 1935.	Av'ge. Annual Rainfall.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

MILLING VALUES OF WHEATS.

Paper read by S. G. Chynoweth at a meeting of Boor's Plains Branch on 5th September.

In the following table are given the average bushel-weight, flour yield, and flour strength of a number of different varieties of wheat. By the term flour strength should be understood the amount of water in quarts required by the 200-lb. sack of flour to make a dough of the proper consistency for baking. The figures, therefore, give the water absorbing power of the flour, which is the most ready and reliable means of determining what is understood by the baker under the term "flour strength." The classification is that adopted in the entries competing for prizes at the Royal Agricultural Society's Show, and includes the three principal classes under which wheat is entered for competition. The "Australian Strong White" class comprises several of Farrer's crosses made with the specific object of providing a hard, strong flour, and white grain, as distinguished from the ordinary hard wheats, which are usually red in colour. It is to the introduction of this class that the greatly improved milling quality of local wheat is due. Australian, and particularly New South Wales wheat, now enjoys a high reputation for milling excellence on the English market, and possesses pre-eminently the valuable characteristic of being suitable for milling without previous blending with other kinds. It is always of excellent colour, and is a strong favourite with English millers on this account. It must be understood that the figures given represent averages taken over a number of yeasr. These figures will vary considerably in different samples, and also in different seasons.

Table Showing Milling Values of Wheat.

Variety.	Weight per Bushel.	Percentage of Flour.	Flour Strength.	Perentage of Dry Gluten.
Australian Strong White Wheats—	Lbs.			
Pusa No. 4	66½	72.3	54.5	12.2

Purple Straw	65½	72.0	42.4	7.3
Gallipoli, Free Gallipoli, Ghurka, Nabawa, rejected by the millers.				

Factors which Lower Quality.—Whilst it may be argued, and correctly so, that so necessary a commodity as wheat must always find a purchaser at a price, there can be no doubt that it is the highest quality article that gives the greatest return. This being the case, growers should endeavour to avoid, as far as possible, producing samples which are defective from the miller's point of view. The chief defects in grain intended for the flour mill, and methods by which their occurrence may be avoided are as follows:—

Smut.—Smut as it is commonly called, or bunt, is a fungus disease, having a very serious residual effect on wheat from a milling point of view, and one which causes considerable losses by reducing the value. It is impossible to determine a definite figure for smut loss, but every grower is aware of its seriousness, either through personal experience or from that of a neighbour. Smutty wheat is treated harshly by millers, as it is very difficult to handle, although certain "smutting" machines will make a fair sample of infected grain, but at a considerable cost. There is no excuse now for smutty wheat, however, as practically complete control is secured by treatment of the seed by dry copper carbonate powder, at the rate of 2ozs. to the bushel of seed.

Damaged Grain.—The presence of damaged grains in a sample of wheat reduces the milling value very considerably. They have serious effects on the quality of the flour, causing a bad colour, imparting an objectionable taint, and reducing its keeping qualities. Furthermore, these damaged grains cannot be removed. The most serious are those that have been heat damaged, but fortunately they are not common under Australian bagged conditions. They are mostly caused by harvesting the wheat while it is unripe, but the majority of growers are sufficiently alive to the necessity of harvesting when the grain is matured, thus largely obviating the danger of this objectionable condition. This trouble is frequently caused by standing bags of wheat in the paddock without placing sufficient logs (and in some cases none at all) for a foundation. If the ground is damp, or if rain should fall, the bottoms of the bags become wet and the wheat is spoilt.

Damaged Patches—These are viewed seriously, and to remove them it frequently happens that a section of the bag is cut away with the bad grain adhering. This causes the bag to be valueless, and is productive of much waste of grain. It is a source of considerable expense, whereas a little care would have saved to the grower the full original value of the wheat.

Bleached, Sprung, and Shot Wheat.—These defects are all caused by excessive external moisture conditions when the grain is just ripening or ripe, and they might be described as three stages of the one complaint—each causing a reduction in value according to the severity of the damage. Such weathering is difficult to control, being largely dependent on climatic condition. An alleviation may be secured by close attention to the sowing of suitable varieties at the right time, by harvesting as expeditiously as possible when the grain is ready, and by sowing fine type varieties free from grain of a different maturing period, so that all ripens at the one time. Bleached wheat is recognised by the loss of colour, for it has a pale, anaemic, and lifeless appearance, with an attendant considerable loss in weight. Sprung wheat is distinguished by the above symptoms together with a bloated appearance of the germ, whilst shot wheat is similar, but with the germs sprouted. Each of the three defects is disliked by millers, the wheat being difficult to store for any length of time, and the flour being much reduced in strength.

Admixtures.—Star thistles, drake, barley, black oats, &c., in quantity constitute a strong objection and thereby reduce the value of the wheat Chaff, white heads, straws, thistle heads, and broken grain are objectionable and are present as the result of faulty setting or operating of the harvester machinery. With a header a minimum of straw should be taken, otherwise it is likely that the sieves will become blocked. It is essential that sieves, beaters, and peg drums be correctly adjusted, and, as far as possible, the machine should be kept moving at a regular pace. These admixtures cause a lot of unnecessary loss and additional work. In the first place the wheat will show a considerably lighter chondrometer weight, bringing the value down immediately; then the bulk of stuff causes a wastage of bags, undue handling, a loss of freight, as the material is practically worthless, and finally it causes additional work and expense at the mill for separating and cleaning

Diseases.—Rust has a very serious indirect effect, as by its action the plant is prevented from supplying the grain with the requisite food material, causing it to be thin and pinched. Such grain, as in other cases of light grain, is relatively low in value. Growers will recollect that in 1916-1917 the f.a.q. weight, in many cases, was light through this cause. Foot-rot, take-all, flag and loose smut, &c., do not themselves directly affect the grain, although whatever grain may form on plants so affected will be found to be pinched and damaged and of little value.

Red Wheat.—As mentioned previously, Australian wheat is prized partly on account of its colour, and is in demand for blending purposes. European buyers have taken exception to the presence of red grain. In view of this it was decided that red wheat should be eliminated from the f.a.q. standard for purposes of export. Consequently it is utmost importance that growers should keep red wheat out of their consignments. (Secretary, S. G. Chynoweth.)

Boor's Plains Agricultural Bureau Field Day.

TYPE OF SHEEP FOR THE FARM.

At a meeting of the South Kilkerran Branch on 2nd September, the Secretary read the following paper:—

The type of sheep for the farmer chiefly depends on the locality in which they are depastured. For instance, in the drier districts it is a mistake to try and keep anything but Merino sheep; they are the most valuable wool producers, and can live on less feed than the English crossbred. It is always advisable to have the best of its kind, as one can always sell a good sheep, whereas he may not be able to sell an inferior sheep.

In the case of the farmer who runs sheep chiefly to keep his land clean, and to get what profits come as a natural result from depasturing them, the chances are that he will buy sheep rather than breed them. In 99 cases out of 100 it is a mistake to buy rubbish. It pays better to buy from a good flock even if they are culls. If one wishes to breed there is no question about the advisability of having good stock to commence with.

It should be the object of the breeder to produce sheep that will build up not only his own flock, but the flocks of his country. The strong woolled Merino growing a good lengthy staple of moderate density is the most profitable in our district.

The blowfly has now become a very serious pest to the sheepfarmer, so much so that many ewes and lambs are lost each year from this cause. The question has frequently been asked, "What is the best thing to do to cope with the trouble," and the best answer is "Prevention is better than cure." To prevent lambing ewes being attacked by the blowfly, it is absolutely necessary to have them breeched and crutched some time before lambing. Bring in the ewes three or four weeks before lambing, and while breeching use great care not to worry the ewe more than necessary. It is a common but bad practice to catch a ewe by the leg. This should not be done. She should be picked up carefully in the arms and sat down.

It is no excuse to say that during lambing time the farmer is too busy to devote any time or care to the ewes. The farmer is keeping his sheep for the purpose of making money, and it will surely pay him to give a little time and attention to the care of his ewes at this period, as by doing so he will increase his percentage of lambs. No matter whether the ewes are old or young, it is the correct thing frequently to walk quietly through the lambing paddock and be at hand to give the assistance that is often required, more especially in the case of young ewes. Care should be taken, however, not unduly to disturb the ewes at this time.

About four to six weeks after the lambs are dropped is the usual time for tailing. One should choose a fine warm day, and start abourt 9 or 10 o'clock in the morning. That gives the lambs a chance to recover a little before the cold of the evening sets in. Care should also be taken not to chase the lambs about too much after being tailed; the quieter they are driven the better.

Dipping sheep is another important thing; it kills tick and other parasites, and also acts as a tonic to the skin. The bath should be well stirred before starting, and the skin should be thoroughly soaked. A large amount of money is lost to some farmers through negligence in connection with the getting up of skins for market. It is advisable to skin the sheep almost immediately after it is killed and to completely strip the carcass, because every extra pound of wool increases the value of the skin. After skinning, the skin should be hung over a rail under cover. The man who skins the sheep carelessly throws the pelts over a fence rail in the sun, leaves it there until he thinks he has a bale and then sends them into the market, is the man who will tell you that it does not pay to save the pelts (Secretary, R. E. Hasting.)

THE FARM HORSE.

The following paper entitled "Management of Farm Horses" was read at a meeting of the Laura Bay Branch on 11th June, by Mr. A. M. Dixon:—

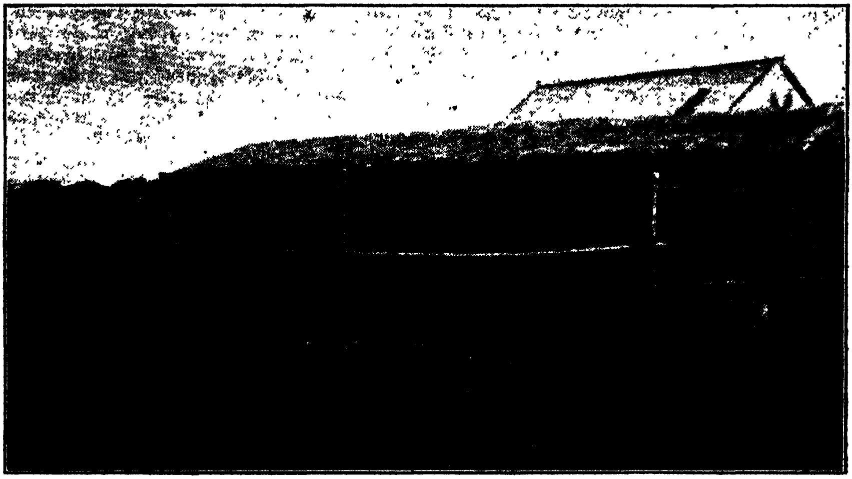
For general farm work the upstanding medium sized active animal with lightly haired legs has no superior. Too much hair on the legs is a disadvantage, when the barley grass goes to seed, because the seeds become matted in the hair around the fetlocks, which is very uncomfortable for the horse, and if not attended is likely to cause trouble

Feeding.—This is the great important item of horse management, and the farmer must use his own discretion to a great extent. The mangers should not be filled and then left until empty before another refill. The horse should receive at each feed just sufficient fodder. Under natural conditions the horse is a bulky feeder, and under working conditions bulk is essential to his feed. Even where concentrated feeding is resorted to, the admixture of chaff prevents over-hasty feeding and promotes digestion. Breakfast should be a small feed, as the horse would not be very hungry. Dinner should be the richest feed of the day, because a horse is usually given only an hour to eat, and the time for digestion is short. The bulk of the feed can be given in the evening, because there is plenty of time for the horse to eat, and no work to follow. Oats rank as one of the best grains for horses. They combine all the elements necessary for nutrition in such proportions that the animal is able to consume a large amount without upsetting the digestion and to extract the greatest possible amount of nourishment from it. Oats have been found to be the finest feed for horses of speed and for those in very hard work. It probably comes nearer the requirements of a concentrate for horses than any other grain. Horses will eat oats in preference to all other grain. Oats may be fed whole or crushed

Watering.—"Water first, feed afterwards" should be the general rule because a horse's stomach is small and water passes directly through the small bowel into the larger one carrying masses of undigested matter with it. However, it is not alway convenient or possible to water before feeding, and the horse very often has a mind of its own. Therefore if some little time elapses between feeding and watering, the horse should not suffer any ill effects. The question also arises whether a horse should drink when hot. It will not hurt him if he is used to it, and on the farm the walk in from the paddock will in most cases cool him down sufficiently. Should any particular horse be inclined to drink too heavily or to be griped in consequence his trouble will cease if the bit is left in his mouth while drinking, because it prevents him from taking too much.

Grooming.—The working horse if in hard condition, cleans himself to a great extent by sweating, and a roll before returning to the stable removes most of the dirt However, in the morning he should be thoroughly groomed. The secret of the art of grooming as an aid to condition is to carry it out with speed. After a long spell the horses shoulders should be washed with cold water immediately the collar is removed. This will harden the shoulders and prevent sores As an aid to hardening or toughening the skin of the shoulders of young horses, these parts can be swabbed daily with a strong solution of salt and water, or an extract made by the boiling of wattle bark. If they are brought to work gradually there should be no trouble with sore shoulders. The shoulders where the collar sits should be kept clean and free from dried sweat and grime, which are likely to set up chafing of the skin. The lining and stuffing of the collar should be kept clean by regular attention and kept soft instead of being allowed to become caked and hard with sweat and dirt.

Every horse requires his own collar, which should be carefully and properly fitted to him and any necessary adjustment made from time to time as the horse loses or gains condition. The collar should fit sufficiently close to enable it to lie quite flat and bear evenly on both shoulders. The collar must be short enough in length to prevent undue rising, but not so short that it will press the windpipe. The test is that the hand and wrist must be able to pass easily between the throat of the collar and the neck of the horse. New collars are a frequent source of sore shoulders. Be sure they fit, and see that the horse is given easy work until the collar is moulded to the shape of the shoulders. (Secretary, P. S. Morrison.)



Stables on Mr. Rodda's Farm at Cunliffe.

HORSE BREEDING.

In the course of a paper entitled "Horse Breeding", read at a meeting of the Nantawarra Branch, Mr. C. H. Belling stated:—"It is necessary for those who are breeding horses for sale to pay attention to the type of horse they are breeding from. After selecting the best mares on the farm, choose a good stallion; do not breed from a mongrel. It is just as easy to breed a good class of horse as it is to breed a poor one. A station horse might work as well as a good one, but he will not look as well in a team. Again, the medium horse will not command nearly the same price as would a good type horse in the sale ring. The farmer who does not keep a stallion, and who patronises a travelling horse, should look well into the pedigree of each horse in his district. The Clydesdale type of horse is preferable for farm work. They usually prove to be good workers, combining strength with pace, and are good tempered, while the mares are good mothers.

Care of the Foal.—When the foal is born catch it and paint the navel with iodine, repeating this for a day or so until the navel is dried up. This will often prevent 'navel-ill.' See that the mare is all right, and has plenty of milk. Feed the mare on chaff and plenty of bran. This will allow her to produce milk, and will keep her open. At the same time let her run in a paddock of good green feed. If the foal refuses to suck, an enema may be necessary. Before doing this apply a little olive oil into the anus with a finger. This often gives relief to the foal and saves straining. Foals should be weaned when five months old, and if necessary they may be kept in a small paddock. The mare should not be forgotten. The day the foal is weaned the mare should still be fed on hard feed. If one has a team working it would not hurt the mare to work. This will help to dry her off. Should the udder become hard and swollen, rub it with olive oil and lard. Foals should be bred in July and August; this will allow them to get plenty of greenfeed, they will shed their coats earlier, and usually look better than a late foal. Castrating should be done in the spring when foals are about 14 months old. It is advisable to obtain the services of a veterinary surgeon. Young horses can be broken in when at the age of 2 years by giving them a few short yokes in the cultivator. This will enable the shoulders to harden. At 3 years old they will stand work much better, and it will give them more time to grow into bigger horses. If a horse is not worked too hard when it is young it will give a longer service, and will sell much more easily. (Secretary, Mervin P. Hamdorf.)

DOES IT PAY TO REAR HEIFER CALVES AND TO BREED PIGS ?

The above was the subject of a paper by Mr. H. J. Hunter at a meeting of the Hope Forest Branch on 2nd September. He stated that if heifer calves were to be reared in order to increase the herd, only the calves from the bigger producers should be kept. If a cow which was a fairly good producer was mated with a bull known to come from a line of heavy producers, a heifer calf would usually turn out to be at least as good as her dam. On the other hand a heifer calf from an indifferent producer should not be kept if it was desired to raise the standard of the herd. If such a calf turned out a good producer her progeny would probably revert to poor producers, unless great care was taken to breed only from good bulls. It would take a long time to build up a big producing herd by rearing heifers from cows which were not worth their place in the herd. All successful dairymen had built up their herds by culling their poorer cows and only keeping heifer calves from cows that paid their way. It was useless to attempt rearing heifers unless cows were mated with a first-class bull. It would scarcely pay to keep them to sell on the market as calves, because they would have to be fed on whole-milk or some other substitute. In rearing a calf from an indifferent cow it should be remembered that the skim milk might otherwise be used for feeding pigs. The value of skim milk as pig food was about 2d. per gallon; a calf would consume 2galls. per day for 4 months. At the present price of pigs a profit of £3 could be made by using as pig feed the amount of milk consumed by one calf, although a certain amount of greenfeed was also needed. A calf of 4 months old therefore cost £3 in feed, and for the next 18 months it ate feed that could be eaten by a producing cow. A cow producing 6lbs. of butterfat per week at 9d. per pound for 9 months would bring in approximately £8. Such a cow could be bought for £5, and therefore showed a profit of £3 in addition to £3 from the pigs that might be sold after being fed on the skim milk.

Pig Breeding.—Sows recommended were Berkshire or Mid-York, which could be mated with either the Large White or Tamworth boar, either cross giving the ideal pig required by butchers and bacon curers. Pigs put on the market as weaners at 8 weeks old were the most profitable. They realised 12s. to 15s. The average sow would farrow a litter of 9 pigs, which would give an income of approximately £6 twice a year. Practically the only expense in putting the pigs on the market would be about 9s. for a bag of pollard. The sow would require about 1½galls. of skim milk per day and as much Chou Moellier or green clover as she could consume while she was dry in between litters, and the pollard would be used in helping her to suckle the young pigs. When the young pigs were 3 weeks old they would drink skim milk and eat greenfeed. The grazing paddocks should be small until the pigs were about 5 weeks old, when they could be turned into larger paddocks. Where there were a good many cows 1 sow could be kept to every 2 cows. All the weaners should not be put on the market at once; some should be kept to consume the skim milk, because one sow would not be able to consume all the skim milk from 2 cows. It was assumed that grazing or other green fodder was available; otherwise it was questionable whether skim milk alone would be profitable. At 8 weeks old pigs would be worth about 13s. 6d. each, while if they were kept a further 8 weeks they were worth about £1, a gain of only 6s. 6d. for the second 8 weeks feeding. A well grown 16 weeks old pig would double his weight in the next 8 weeks and should then be worth at least £2, a gain of £1. Against the £1 would have to be debited about 6s. for barley or wheat to put the pig into condition for bacon, otherwise the fat would be too soft and the price would be lower. Very little was gained in rearing pigs to small porkers. It cost only 14s. more to keep them until they were suitable for bacon. It would be preferable to obtain a further 2 sows to have 1 farrow about every 8 weeks, so that little pigs would be available to consume the milk regularly. It appeared that pigs should either be sold as weaners or kept until they were baconers. (Secretary, H. J. Hunter.)

THE HOME GARDEN.

Paper read by Mr. A. M. Twartz at a meeting of the Sutherlands Branch on 12th September:—*Soil.*—If the surface soil is not as desired it should be removed to a depth of 18in. and a sandy loam carted in. The area of the garden should be large enough to allow hedges to be planted. The fence should be 5ft. high and netted. For a hedge almonds should be planted, preferably Brandis or I.X.L., because these grow upright. Almonds grow in any soil, shed their leaves in winter, and are a profitable hedge. If the roots become troublesome they should be cut by digging a trench 3ft. deep every three years. The trench should not be left open as this causes the roots to travel around. The paths should be higher than the beds. *Water.*—A reliable water supply is absolutely necessary. To rely on the natural rains will not suffice. Overhead watering with a sprinkler is one of the best methods when the plants are small. Trees should be watered around the stem. *Manure.*—Sheep manure would be preferable to any other, cow manure next best. If the manure is lying around it should be heaped up after 15 to 20 points of rain have fallen. This method tends to kill weed seeds. Liquid manure can be made by filling a kerosene tin half full of manure and filling it with water. The liquid should be the colour of weak tea. Superphosphate can be used with success at the rate of one-third of an ounce per square yard. Farmyard manure or sheep manure should be dug into the soil before planting. When the plants need a stimulant, manure can also be placed between the rows. This method also checks weeds. *Plants and Seeds.*—A good plan is to follow Yates's garden calendar or Hackett's "Reminder." It is necessary to sow a bed of your favourite dish each month so as to have a continuous supply throughout the year. A bed of rhubarb should be in every garden. It comes in when other fruit is scarce. Cabbages, cauliflowers, carrots, lettuce, peas, onions, and shallots can be grown without expert knowledge. The home garden is not complete without flowers. A few fruit trees of apple, pear, apricot, nectarine, peach and fig will provide useful fruits for the housewife. A careful watch must be kept for slugs and snails. A good mixture can be made from Paris green and bran sprinkled between the plants. *Cultivation.*—By the frequent use of the hoe and plough weeds are destroyed and the surface kept loose. It is best to prepare the bed some time before planting. When a bed has grown a root crop put in a leaf crop next. *Points from Discussion.*—Black leaf 40 was regarded as the best spray for red spiders, and Paris green for slugs. Ashes were good for tomatoes if dug in when fresh. If not used at once they should be bagged up and put away in a shed. Yorkshire Hero was the best pea locally; beans were also easily grown. A lemon or orange tree should be grown; all the water from the house can be given it, including soapy water. Best place for melons was where a creek ran out, or in some sandy place. Tomatoes should be trained and pruned, and kept up with bamboo sticks. Brown skin onions were the best if they were to be kept indefinitely. Short carrots and bush marrows were also regarded as the best varieties. Cauliflowers should be sown with protection, planted in the evening, and covered with tins for a few days. They should receive a light watering regularly, and they would be ready in about six months. Sheep droppings were considered to be best for sandy loam, although one member preferred leaf mould. Watering tomatoes overhead was regarded as unwise by some. Ashes put around the stem of a tree would prevent ants from eating the fruit. Dahlias should not be watered too much, but it should be done regularly. They should not be allowed to grow higher than 2½ft. (Secretary, L. B. Doecke.)

POINTS ON THE CARE AND OPERATION OF FARM STATIONARY ENGINES.

The following paper was read by Mr. A. J. Pengilly at a recent meeting of the Alawoona Branch:—Nearly all farmers have need of some form of supply of power for belt work. Chaffcutters, crushers, &c., all require the use of some class of engine to supply the power to drive them. The makes and types of engines used vary considerably, but few of them exceed the 20 b.h.p. rating, and are generally, therefore, classed as light stationary engines.

They also fall into another classification, viz., petrol engines, spark ignition, petrol-kerosene engines, compression-ignition kerosene engines, and Diesel types using crude oil as fuel. The aim of this paper is to deal with the operation and some points on the care of each type. Stationary petrol engines are generally small engines of a low b.h.p., of both air and water-cooled types. Of these the predominating type for small engines up to 4 h.p. is "hopper cooled," meaning that the excess heat generated in the cylinder is dissipated by a hopper of water which completely surrounds it. An erroneous idea with which I have come in contact is that one need not be particular about cleanliness of the cooling water. With this type of engine one needs to be more particular than with any other, for boiling takes place more often during their operation. A deposit of only 1/16th inch will seriously interfere with the proper cooling of the cylinder, and will result in rapid overheating. Overheating in its turn brings about trouble due to the rapid breaking down of the old film in the cylinder, resulting in worn pistons, cylinders, and rings, or possibly scored and burned pistons and cylinders.

When the manufacturer builds the engine he delivers it to the customer in most cases with all adjustments made, to enable the engine to run and work as he designed it. A common error is made by owners in tampering unnecessarily with the factory settings. This particularly refers to the governed speed. Although this is adjustable in nearly all engines, the speed set by the maker will give the best service. Racing an engine results in rapid deterioration of working parts, particularly bearings and journals. If it is necessary to race an engine to make it do a certain job, either it is in urgent need of overhaul or is not powerful enough to do the work required of it. The only exception to the rule against interference with the governor setting may be to enable the engine to idle satisfactorily with a very light load. However, this may generally be accomplished by careful adjustment of the throttle control. Valve adjustments should be checked at frequent intervals, for too great a tappet or rocker clearance results in imperfect scavenging of the burnt gases, as well as a weak explosion, due to insufficient space for the entrance of the full charge. Insufficient clearance results in the valves not closing properly, and leads to burnt valves and pitted valves and seatings; also sticking valves and worn guides may result, due to destruction of the lubricating film on these parts. The ignition on petrol engines is invariably of the spark type. The high tension current is supplied either by a strip sparking device or a magneto. In either case the structure of these units is delicate, and therefore costly. Oil and grease on damp and dust naturally interfere with the operation of these units, and do serious damage to the insulation of windings and cables. The continued entrance of oil and dirt will often result in burnt-out armatures and windings. Therefore the magneto or other device should be kept scrupulously clean and protected from all sources of dust and dirt. The best method is to have a dirt-proof cover to cover over the magneto completely. Magnetos should only be lubricated as specifically laid down by the manufacturers. Trouble in these units should only be rectified by a man who thoroughly understands them, and they should be treated with respect by the uninitiated. The magneto is the most valuable unit on an engine, costing anything from £5 to £30, so it is well worth taking care of. Spark plug cables should also be protected from dirt, especially oil, as it rots rubber insulation very rapidly. Spark plugs should be set to the gap set out by the maker in the engine instructions, usually a space of 1/32in. separating the two points. The porcelains shoud be kept clean to avoid short circuiting, and all connections should be clean, strong, and definite.

One comes now to the subject of lubrication. Although so much emphasis is placed on it by manufacturers, practical men, and oil companies there is still a tendency to be careless in this respect. If an engine is worth the amount of money one pays for it, it deserves the best lubrication possible, and will then give its best service. There are good oils and there are lots of things resembling them but *not* just as good. Although the major oil companies charge high prices for their commodities, they sell good quality products which can be depended on, and good oil is cheap in the long run, as any "big-power" user will tell you.

Repairing small petrol engines, replacements of bearings, &c., are not very difficult to carry out if due care is taken. When removing parts, put them aside and mark them, or place them so that you will be able to recognise their positions when you want to re-assemble them. Most of this work is simple enough if one takes a reasonable amount of care. Do not be frightened that things will not go into their positions again. When cylinders, pistons, and rings become worn, resulting in loss of compression, new rings will often remedy the trouble until a rebore becomes necessary. Rings are supplied generally in four standard oversizes, viz., .001in., .003in., .005in., and .01in., and usually one of these sizes will make up for the loss of compression. The rings should be a good fit in the grooves, and when fitted squarely in the cylinder there should be a very small gap between the two ends. Rings are very brittle, and care should be exercised in fitting them to the piston. The best method to adopt is to slide the ring on over four thin metal strips, and then, withdrawing the strips, let the ring fall into its correct groove. Grooves should be first cleaned of all carbon and burnt oil deposits.

The foregoing points refer also to larger petrol engines, though these generally have a water jacket for cooling, through which the water circulates on a thermo-syphon principle. As before stated the cooling water should be clean and free from grease and other impurities. A very effective cleanser for a corroded water jacket is a solution of common washing soda, 1lb. to each gallon of water. Let it circulate for a full day or so of work. It is then drained out, the system flushed with clean water, and then refilled with clean water.

The design of spark-ignition petrol-kerosene engines very closely follows ordinary petrol engines, except that they are fitted with an auxiliary tank for petrol, and have some two-way arrangement for supplying the petrol and kerosene to the carburettor or vapouriser. These engines are designed to start on petrol when cold, and when they have become warmed up, to switch over to kerosense for working. The main thing to guard against is the error of changing to kerosene before they are thoroughly warm. This has the effect of breaking down the lubricating film in the cylinder due to unvapourised kerosene entering it, with resultant rapid wear, and in the case of enclosed crankcase, splash-lubricated types, a dilution of the lubricating oil, which is then unable to stand up to its work and burns, resulting in rapid wear and heavy carbon deposits in combusion chambers and on piston heads. Since these engines are generally of a fast-moving type, the piston speed is anything up to 1,000ft. per minute, and the necessity for good, undiluted lubricating oil is self evident.

The next class is the kerosene compression-ignition class, which depends on heat generated within itself and stored in the combustion chamber. These engines are usually much heavier in construction than petrol and petrol-kerosene engines, and run at slower speed. Difficulty in starting these types is sometimes met with, but this is usually due to the engine not being heated enough by the lamp or else it is too hot, back-firing occurring in the latter case. Mechanical causes of hard starting may be due to loss of compression through worn cylinders, pistons, or rings, or worn injection gear, or injection gear out of adjustment. A useful hint which may be applied to these engines is to use commercial castor oil for cylinder lubrication. This gives a much better seal, and holds the compression better than a heavy mineral oil. Castor oil is really the ideal lubricating oil, as it resists heat better, and was very widely used for aeroplane lubrication during the World War. The rocker clearances should be adjusted to their correct spacings, as too much play results in noisy cam action. The journals of these engines are usually lubricated by either wick syphon lubricators or ring oilers, and a good quality of flowing oil should be used in these. The big end connecting-rod bearing is generally oil lubricated by a closed cup. The piston pin is usually lubricated by surplus oil from the piston. These engines are usually thermo-syphon cooled, and have a large cooling tank to provide a large supply of cool water. Care should be taken in some types to prevent the injector valve opening, due to suction. This is prevented by adjusting the tension on the spring. If this is not watched, the engine may get out of control or "bolt," the governor having no control in such an emergency, since most of the types of governor used on these engines work on the "hit-or-miss" principle.

Lastly we come to the class of engine operating on the Diesel principle, using crude oil as fuel. Very few of these engines are in the hands of farmers at present, as they are really only a recent development as a small power unit. For this reason I do not propose to deal with them at any length. They ignite their charge by heat generated by their very high compression (anything up to 800lbs. per square inch), and the fuel is injected under pressure during the power stroke, the piston compressing air only on the compression stroke. They are much more complicated than ordinary kerosene engines, but are much cheaper to run because of the low fuel cost.

Possibly some farmers have engines operating on the "two-stroke" principle, so I will endeavour to explain the difference between the "two-stroke" and "four-stroke" engines. In the "four-stroke" the cycle of operations for one complete power impulse is as follows:—On the outward stroke the inlet valve opens, and a mixture of fuel vapour and air is drawn in. On the return of the piston the inlet valve closes, and the charge is compressed, making it much more easy to ignite. Just before the piston reaches the back dead-centre the charge is ignited and explodes, and forces the piston violently outward on the power stroke. On the return of the piston the exhaust valve opens and the exhaust gases are forced from the cylinder in readiness for the repetition of the cycle of operations at the beginning of the next outward stroke.

In the "two-stroke" engine the piston acts as its own valves by covering and uncovering openings or "ports" in the cylinder walls. The crankcase is sealed, and a by-pass leads from it to the inlet port of the cylinder. The fuel vapour and air is drawn into the crankcase through a manifold and "no-return" valve by the partial vacuum created periodically by the piston as will be explained later. On the first outward stroke the downward movement of the piston creates a pressure on the gas in the crankcase. When almost at the end of its stroke, the inlet port is uncovered, and the compressed gas rushes into the cylinder. The returning piston now covers the ports, and the gas so trapped in the cylinder is compressed. It is then ignited and explodes, forcing the piston outwards until the exhaust port is uncovered, a little before the inlet port is uncovered. The burnt gases then start to escape, and as the piston progresses on its stroke it uncovers the inlet port, and, the fuel having been compressed by the outward movement of the piston, it rushes into the cylinder, and in doing so forces out the remainder of the exhaust charge. The piston returns as before, and traps some more fuel in the manner stated, and the cycle is repeated. As the piston goes back, however, it creates a partial vacuum in the sealed crankcase and draws, therefore, a further supply of fuel vapour into it in readiness for the next stroke the one-way valve.

"The "two-stroke" engine is suitable only for light work, speaking generally, and is only satisfactory at high speeds. They are wasteful of fuel, and if run at slow speeds have an uneven power output, and tend to operate as a "four-stroke." Their chief advantage is that there is a power stroke at every revolution of the crankshaft, instead of every second revolution as is the case of a "four-stroke" engine. The "four-stroke" is more definite in action, and gives a relatively steady power output over all speeds, and is more economical with its fuel.

The following are a few points which may be of use in setting up drives:—

1. To find the required diameter of a driven pulley if the speed required is known:—Divide the produce of diameter and revs./minute of the *driver* by the required number of revs./minute of the *driven*.

2. Four-ply cotton and canvas belting is equal to single thickness leather belting in strength, and so on.

3. To find the length required for an open belt:—To twice the distance between the shaft centres add 3¼ times half the sum of the pulley diameters. Crossed belt lengths may be *approximately* calculated by using 3⅜ in the foregoing formula.

4. To find the required width of single leather belt for a given horsepower to be transmitted:—Multiply the horspower by 33,000, and divide it by the velocity of the belt (ft./min.) plus the allowable effective pull per inch in width. For all practical purposes this may be taken as 35lbs. for single leather belt.

5. To find the horsepower of a belt:—Multiply the width in inches, the allowable pull and the speed, and divide by 33,000.

6. A double leather belt will need to be only seven-tenths as wide as a single leather belt for the same power, and conversely a double belt will transmit ten-sevenths more power than a single belt of the same width.

7. New leather belts will stretch from ¼in. to ½in. per foot of length. Rubber belts are said to stretch continuously, and cotton and canvas belts stretch very little. (Secretary, A. J. Pengilly.)

Inspecting Mr. Magor's Pastures at Myponga Bureau Field Day.

Making Silage on Mr. R. Magor's Property at Myponga.

NOXIOUS WEEDS.

Mr. E. Kleinig, in the course of a paper read at the meeting of the Koonunga Branch on 11th September, stated that legislation to deal with noxious plants was passed by Parliament more than 50 years ago. However, a visitor passing through portions of the district at present would not think that noxious weed legislation existed, especially in the grazing country, where he would see nothing but star thistles and artichokes—the artichoke, however, was a good fodder for sheep when it was dry. Star thistle was a tall, slender plant, not eaten by stock except when it was very young. Yellow cockspur resembled the Saffron thistle, but was much stronger in growth and was never eaten by stock. Cape Tulip was very poisonous, and difficult to eradicate, and it spread very rapidly. There has been complaints about it locally. Cape Tulip was often planted in gardens, from which it could escape and ruin good grazing land. The Bathurst Burr preferred warm, moist conditions, like the River Murray districts. There were a number of plants of it in the district, but as they were kept under control more easily than other weeds, they were not likely to spread so quickly. Boxthorn was a dangerous weed and should be watched. Because of its hardiness, it was one of the first plants used for hedges. There were not many in the district, although in places they could be seen for miles along the roadway, and great care should be taken to prevent them from getting out of control. The Boxthorn produced red berries, which were eaten by birds, and thus the seeds were distributed by them. Boxthorn grew very rapidly and soon took possession of any waste land. It could easily be replaced for hedges by some other plant which was not so troublesome.

In purchasing seed, it was important to see that it was free from foreign seeds, because once weed seeds germinated, eradication was often very difficult and might prove very expensive if it were not done at an early stage. Good cultivation, combined with heavy stocking would kill many bad weeds. Sodium chlorate was a very effective spray in checking weeds (not sodium chloride, which was common salt). Sodium chlorate cost 8d. to 9d. per lb., and was used at the rate of 1lb. to 1 gallon of water, and sprayed on the foliage with an ordinary spray-pump. (Secretary, H. Mibus.)

A Crop entered by Mr. B. Jaensch, of Woodchester, in the Southern Competition.

QUESTION BOX.

At a "Question Box" meeting of the Coonawarra Branch held on September 5th the following questions were dealt with:—*Question*: Correct method of mixing ingredients of Bordeaux mixture? *Reply*: Most members favoured adding the lime to the bluestone solution. *Question*: Quickest method of dissolving bluestone? *Reply*: Place bluestone in a calico bag and hang it on the edge of a tub of cold water. Members did not advise heating the water. *Question*: Most suitable manure to use on old apricot trees likely to carry a heavy crop? *Reply*: Sulphate of ammonia was suggested, but was considered to have detrimental effects over a number of years. For the district best results would be obtained from 45 per cent. superphosphate. *Question*: Spray for an orange tree affected with black scale. *Reply*: Members agreed on the use of red oil. (Secretary, J. M. Kain.)

A meeting of the Chapman Bore Branch held on 12th August took the form of a "Question Box." The following questions were dealt with:—*Question*: Best breed of cattle for milk production in the mallee? *Reply*: The Ayrshire was a hardy type and a good producer. The Jersey and Holstein were also favoured. The milking Shorthorn was useful because of the better value for slaughtering. *Question*: Most suitable ram to mate with Merino ewes for fat lamb production. *Reply*: Dorset Horn was favoured. *Question*: Best oat for feed purposes? *Reply*: Mulga was the leading variety; Early Kherson and Palestine were also good varieties. *Question*: Cure for horses rubbing off their hair. *Reply*: Irritation probably caused by parasites. Wash with water containing phenyle. *Question*: Does it pay to sow more than 45lbs. of wheat per acre? *Reply*: On new land 60lbs. per acre could be sown in order to provide as much straw as possible for burning. On fallow 45lbs. of graded seed was considered enough. *Question*: Should one commence putting in fence wires from the top or the bottom of the posts? *Reply*: If wires were put in from the top the strainer posts were not likely to give and cause the wires to slacken. *Question*: Easy method of pulling old posts. *Reply*: Loosen soil around the posts, and if a jack was not available, the posts could be pulled by using a wagon and team. *Question*: Best implement for fallowing, share plough or disc? *Reply*: The share plough was best for local conditions. *Question*: Is two-year fallow advisable? *Reply*: The benefit from two years' fallow would not be sufficient to pay for the extra work. *Question*: Best time to commence sowing wheat. *Reply*: New land should be commenced early in April, and the fallows should be completed not later than the middle of June, providing seasonable rains fell. *Question*: Best variety of oats for new land. *Reply*: Algerian oats gave a fair return, and provided a good crop of straw for a burn to kill shoots. *Question*: How to keep weevil out of wheat stored on the farm. *Reply*: Wheat stored in bulk was not so likely to be attacked as wheat stored in bags. Sprinkling sulphur between the bags and on the floor was recommended. *Question*: How to check sand drift? *Reply*: Sowing and topdressing pasture would tend to keep the soil bound by the roots of the plants. (Secretary, J. P. Krollig.)

The inaugural meeting of the Karte Branch was held on May 30th, followed by a social and dance on June 14th. The subject of the next meeting on July 10th was an address by Mr. R. L. Griffiths (District Agricultural Instructor), who dealt with the question of drift. On August 14th a "Question Box" meeting was held. The following were among the questions dealt with:—*Question*: Cheapest method of destroying rabbits. *Reply*: Poisoned oats laid on a trail. A mixture of 1oz. of strychnine to 14lbs. of wheat with brown sugar added was also recommended. *Question*: Best sideline for the district. *Reply*: Dairying and poultry were best while blocks were new, followed by sheep when fences were erected and feed was available. (Secretary, M. E. Small.)

Visitors at the Annual Field Day at Kybybolite Experimental Farm listening to an Address by Mr. H. B. Barlow (Chief Dairy Instructor) on Fodder Conservation.

HOME TANNING.

[The following paper was read by Mr. L. C. COLLETT at a meeting of the Currency Creek Branch on 19th August.]

In order to make one's own leather, or to tan or cure furred skins for rugs, mats, etc., one must be prepared for a fair amount of work.

Tanning a Hide for Leather.—Selection: Take particular care in selecting a hide to get one that is all the one colour, has no brands or bruises, and is skinned from the beast cleanly and is not cut or scored by the knife. A black hide is preferable because it is more even in thickness and makes stronger leather than a yellow or red one. Sell a patchy hide rather than tan it, because a patch on the skin means weak leather.

Preparing for the Tan.—Place the hide flesh side upwards on a smooth log and, with the aid of a sharp knife, remove every particle of fat and flesh adhering to it.

Next place about four to six pounds of lime in a tin and add water to half fill the vessel. Stir well, put the skin in this, and in about four days the hair will rub off easily.

A shovelful of ashes mixed with the lime will usually stop the lime from working too severely on the hide and burning it.

When the hair is all off the skin, give the inside a good rubbing with a brick, or a piece of sandstone to take off any flesh that may have been left on in the process of fleshing.

The skin will now be pink and will contain lime. If this lime is left in, the finished leather will be brittle.

To remove the lime from the hide, mix up a shovelful of fowl manure in a half kerosene tin of water and steep the hide for three or four days. The lime will be out of the hide when the latter is again white. Wash the hide in clean water after removal from the bucket and before placing it in the tan.

Preparing the tan is not so complicated: Take a kerosene tin of crushed wattle bark and water and boil it until the tin is only half full. Add fresh bark and more water to the old and re-boil for another half hour.

Pour this mixture into the tan tub and add clear water until the tan is the colour of weak tea. Allow it to cool and place in it the clean hide. Turn the hide every few days, and after about six weeks it should be ready for the first examination.

When examining the hide make sure the neck, *i.e.*, the thickest part of the hide, is tanned completely through. If not, a green line will be seen in the centre of the cut you make, and a fortnight or so more will be required before the tanning is complete.

Finishing the hide is simple—Take it out of the tan and oil it, either on the outside or on the inside, with neatsfoot oil, mutton fat, or any other animal fat. Allow it to dry, either hanging over a rail or pegged out on a big board, such as a barn floor. If you want a particularly good job made of it, before oiling place it on a smooth board that will not let any air through and rub the hide either outside or inside with a smooth piece of wood. I use a round stick about 1½ins. in thickness. and 2ft. long. Do not allow the stick to turn in your hand but hold it rigid and rub it over the hide under pressure.

Polishing is an easy matter. Take the dried products and damp a piece at a time, rubbing the dampened piece in the same manner as when smoothing, until it is highly polished.

Making Greenhide, Using Skim-Milk and Soap.—Peg a fresh hide in the shade to dry for a few hours. When nearly dry dampen it thoroughly with skim-milk and brush it well with a stiff brush. Apply the milk daily for 10 days, not allowing any part to become dry. Now rub into it a bar of common soap until the whole bar is used, a process extending over several days.

Curing a Cowhide, White.—Remove the hair as before. Dissolve 3lbs. alum, 1½lbs. salt, and half pint of washing soda in hot water. Add 2galls. of water and soak the hide for a week. Dry in the shade, stretching whilst drying.

Furred Skins.—To tan a number of skins with wattle bark, clean the skins of fat and flesh and immerse them in the tan for a fortnight, changing the tan at the end of the first week. Work the skins whilst they are dry and sandpaper the inside.

Curing Skins for Rugs.—Dissolve separately ¼lb. salt, ¼lb. alum, ½oz. borax in hot water and mix solutions. Add enough bran to make a paste and spread it on the flesh side of the skins, rubbing it well in. Repeat the process for a week. Wash the skins well and rub whilst drying to soften them.

Curing Furred Skins White.—Pour 5 quarts of boiling water over 2 quarts of bran and strain the mixture. Make an equal quantity of blood-warm water saturated with salt. Mix the two solutions and add 1oz. of sulphuric acid to each gallon. Immerse the skins in the mixture and stir for 20 minutes. Rinse in clean water and stretch and pull whilst drying. (Secretary, D. Jeff-Gordon.)

PIG RAISING.

In a paper read at a meeting of the Brownlow Branch on 14th August, Mr. G. H. Roocke stated that sows in pig did not need much looking after. A small quantity of grain, a supply of water, and a little greenfeed was sufficient until farrowing time. It was an advantage to have the pigs in a large run sown with barley or oats. The only additional feed needed by mature sows would be a ration of ¾ pint of grain, although young sows would need more feed to ensure that their growth was not checked. Small pigs being fed for market should receive as much grain as they would eat, as well as plenty of skim milk. A clean run was essential. Pigs of the right type, if fed well, should be baconers at the age of 5 or 6 months. If the pigs were fed on grain it should be soaked for at least 12 hours before feeding. Best results were obtained from crushed grain, but profits were not large enough to pay the expense of the crushing. Grain should not be boiled, because boiling removed a great amount of its food value. In feeding old sows and hogs with grain, a fair amount of chaff could be mixed with the grain in order to fill them up. A sow for breeding should be of good shape and length and should have at least 12 teats in case she had a large litter. If a young sow had a large litter she should be kept for breeding, because in all probability she would continue to have big litters. A big litter of from 8 to 10 pigs could be reared quite comfortably by one sow. The most popular breed for the present-day market was the Large White crossed with the Berkshire. When breeding the above cross the Large White boar should be pure-bred, because the piglet from a Large White would always be white, whatever the colour of the sow. The Duroc Jersey and Tamworth were good breeds to cross with the Berkshire. The Duroc Jersey was very hardy and would thrive on much less feed than would other breeds. *Housing.*—The farrowing pen should be about 17ft. by 12ft. with a farrowing rail 6ins. high and 6ins. from the wall. The pen should be warm and free from draughts and should be provided with a bedding of short straw or cocky chaff. Long straw should not be used, because the little pigs were likely to get underneath it and be crushed to death by the sow. Weaning should take place at from 6 to 8 weeks. At 3 to 4 weeks the piglets would commence to eat by themselves and should be allowed to go out of the pen through a slip hole to feed so that the sow could not eat their food. Boar pigs should be castrated at about 4 weeks of age. (Secretary, A. R. Steinborner.)

MARKET GARDENING.

The following paper was read by Mr. L. Neighbour at a meeting of the Carey's Gully Branch held on 5th August:—We have many problems to overcome in the production of fruit and vegetables for market, but our greatest problem is to dispose of our produce at a profit. We cannot expect to make any great change in our present system of marketing nor entirely eliminate its faults, and the only thing left for us to do is to make the best of it.

The market is composed of a large number of individual growers, to a large extent in competition with each other. There is a little co-operation among a section of growers who endeavour to stabilise prices of a few lines to a certain extent, but their efforts are only partly successful owing to the large number of growers who will not come into line with them. It is almost impossible to get every individual grower to take an intelligent view of the situation, which would result in a definite all-round improvement.

Individual growers can get the best results under present conditions by paying attention to quality, preparation for market, and continuity of supplies. Quality of produce will give ready sale at possibly a price slightly in advance of general market rates, but quality itself is not sufficient to enhance sales and prices unless the produce is attractively prepared for market. Inferior produce should be eliminated as far as possible by the grower who wishes to obtain the best price for his produce. If all growers would do this the market would never be over-supplied. The demand would be increased if the best quality was always obtainable by the consumers. The grower should also endeavour to have a regular supply throughout the season, as by doing this he can keep his customers together and need have very little to sell in the open market. He should also endeavour to select his customers according to the value of their services to him. I regard the retailers as salesmen whose duty it is to sell any products to the consumers in the best possible condition and at the best possible price. The retailer who is willing to pay a little better than average market price for a better quality article is worth looking after, and is perhaps not such a rarity as it would appear.

Growers would often obtain better prices by the exercise of a little will-power, but too many follow the line of least resistance and give in to the other fellow's "won't power." Often a grower who finds it difficult to sell his produce at the ruling market rates, probably owing to its being of inferior quality or otherwise through having an over-supply, will reduce his prices and cause a general decline in market prices. This could be avoided by either discarding anything but the best quality, or in the event of having over-supplies of good quality produce, by realising that it is better to lose some of the produce at home than to take it to market and obtain less money for more work.

When the market is over-supplied I consider that it is a mistake to reduce prices, as this does not appreciably increase sales. Growers generally should be advised to reduce the quantity they bring to market, a general meeting to be called for this purpose if necessary.

Genuine distributors would welcome action on these lines, as it would tend to eliminate the cheapjack, who is a menace to the industry generally. An improvement might be made by having a definite closing time for business in the market. Most of the cheapjack business is done after the better class retailers have obtained their supplies and departed on their rounds. A definite closing-time would force the cheapjacks to compete with the genuine retailers on an equal footing. It might be objected that some growers would sacrifice their produce as closing time approached, but I think that the idea is at least worth a trial. (Secretary, F. W. Sharp.)

LONE GUM AND MONASH.

At a recent meeting of the Monash Agricultural Bureau, the principal speakers were Messrs. N. Fotheringham (Manager, Government Orchard, Berri) and F. R. Arndt (District Horticultural Instructor).

Mr. Fotheringham dealt with the practice of "tipping" the vines, mainly sultanas. He said the object of "tipping" was mostly to control the luxuriant growth by tipping off the ends of the shoots and encouraging the lateral growth, with the exception of the central shoots, which were to be the canes for the next year. Central shoots should be tipped when of sufficient length to lay down for the following year. Tests were being carried out at the Government Orchard in connection with "tipping." Up to date it had been noted that on identical rows "tipped" and "untipped" vines had shown 4,400lbs. dried to the acre and 3,900lbs. respectively. Only strong vines, of course, should be treated. It was apparent from observations that "topped' vines were at a disadvantage when it came to drying, the check reflecting back on the fruit, so that the "topped" vines dried off lighter than the fruit from the "untopped." In cincturing the currants, the best results had been obtained by means of the double knife-cut at the time when the caps were falling freely. Mr. Fotheringham recommended putting a strip of wax bandage around the cincture. This allowed the fruit to set, and healed the cut up quickly. Tests with cincturing the sultana had shown that it improved the yield, but the fruit itself was not good for dipping, and so the practice could not be recommended by him for sultanas.

Mr. Arndt spoke of spraying practices. Very little disease had shown up this season. With currants, oidium had to be contended with, and it was always essential to treat for this. Sulphur blown on to the vines was effective, but quite a lot were now using colloidal sulphur, which was mixed with water, 2lbs. to 100galls., and sprayed on to the vines. There was slight oidium with the Gordo vine, and this year especially there had been a great deal of erinose showing up. Sulphur was the cure for this. Black smut was very bad this year, especially on the late Valencia oranges. It was essential that this should be checked, and it was due to the black scale. Besides the damage to the tree, black smut on the fruit meant that it had to be washed, with the consequent extra cost in handling. Trees should be sprayed with white oil at the end of January or early in February to check the brood at that time.

WOMEN'S BRANCHES.

SWEET CORN OR TABLE MAIZE.

[Paper by Mrs. E. B. FRANKLIN at a meeting of Karte Branch on 14th August.]

As spring is approaching one begins to think of the summer kitchen garden, fruits, salads, &c., and why not try a little sweet corn. Many of us country women have in the past missed much by not adding this delicious article of food to our kitchen garden list. There are quite a number of ways of using and cooking sweet corn. This one is delicious:—

Pick the cobs just as the tassel is drying off and put them into a saucepan containing boiling water. Add a pinch of salt and boil for about 20 minutes. Take up and serve as a vegetable, spread a little butter on and sprinkle pepper and salt on each cob. You require two forks to get the little grains off—the cob or centre. To take hold of the cob as daintily as possible in the fingers, much the way a small child does a slice of watermelon is indeed quite an easy way to eat it. It is also used as a salad and in salads. I think a little sugar could be added in the boiling as is done with green peas.

It is quite a change for desert with cream and sugar. It is a wonderful substitute on a day when meat is scarce or the weather is too hot to eat meat.

It makes a delicious sweet by roasting the grains in a close iron vessel until they pop, then they are taken out and dusted with powdered sugar, making "Pop Corn." There are a variety of kinds to choose from, Country Gentleman being a great favourite, but a little on the late side.

Sow from August to October, in highly manured soil in a row and a foot apart. Mulch with manure and water freely. (Secretary, Mrs. F. N. Atze.)

HOME GARDENING.

"Gardening as a Hobby in the Country" was the subject of this paper read by Sister Mudge at a meeting of the Snowtown Branch:—In most instances we are unable to choose the situation of our gardens but must make the best of what we have. The first and most essential thing to do is to provide a breakwind. If you have or can afford to have an iron fence erected surrounding your garden you are indeed fortunate. A good breakwind can be made by planting bamboos either in rows or in clumps. I find them very easily grown once they get a start. Trench the ground and manure well, give plenty of water for 2 or 3 weeks, or until they get a good hold. Once they are well established they require no water.

A hedge which is used a good deal and will grow with very little water and attention is Native Myrtle. If kept trimmed, it looks very green and fresh, but it is a robber. Wormwood may also be used and is really quite effective, but must be kept trimmed and tidy. There are less hardy ones such as the Cupresses, Coprosma, Kaffir Apple, etc.

A fence built of bamboos entwined between wires or bars, and with creepers or roses grown over it looks quite nice and effective, and small plants and bulbs may be grown right under it as it takes no nourishment from the soil. Morning Glory or Dolicos may be used with effect.

If your have water laid on, you will be able to grow much more and with very much less trouble and time. Much can be done with waste water and all water should be put into buckets or tubs to be used as wanted.

Such hardy flowers as Antirrhinums, Wallflowers, Gaillardias, Geraniums, etc., may be grown with this water, which otherwise would be wasted.

It is necessary to manure and prepare the ground, and afterwards keep the ground well worked up and loose. By giving them a good soaking once or twice a week much better results are obtained than by sprinkling the surface. This is best in all gardening.

Drains, etc., from the kitchen or laundry may be used to advantage by planting Cannas where the water soaks in as these plants cannot get too much water. They keep the spot from becoming offensive and boggy, besides being a bright green spot nearly all the year. Use plenty of horse or cow manure, both of which can be easily procured on a farm.

Rockeries are very fashionable at present and can be built quite easily and quickly if you have some suitable stones handy. These may be built on a spot under trees or anywhere where it is difficult to grow flowers. If planted with Succulents, which grow quickly and easily and take very little water and attention, they are most effective. When building rockeries keep in mind the idea of hills and valleys and build your rockery accordingly. If you can arrange a small pool for fish or bird-bath and drinking pool so much the better. One or more lawns always look green, cool and fresh, and if a large area, they help to fill in the space. For these, tap water should be laid on. If water is scarce and you haven't the time to grow annuals, which need constant attention, shrubs are quite a good idea. Many quite hardy ones are obtainable, and I think we would be wise to go in for our own wild and native shrubs more. These are hardy and stand up to droughts one they become established.

Two or three shrubs planted annually enable one to work up quite a good show, and most folks have enough waste water to grow 2 or 3, as after the first year they take much less water. Give these a good soaking once a week to get good results. By this means in a few years you have quite a bright little spot without a lot of work.

If water is scarce one may have a very good show in the spring by planting such hardy annuals as Antirrhinums, Larkspurs, Hollyhocks, Shirley Poppies, Stocks, etc., and only keep some Geraniums and possibly some Sunflowers and a small bed of Petunias going in the summer, allowing the rest of the garden to lie idle until the following winter. A good plan too is to grow bulbs in the winter as the winter rains will give them all the water necessary. (Secretary, Mrs. A. Hocking.)

"Planning the Flower Garden" was the subject of the following paper by Mrs. S. Smith at a meeting of the Rendelsham Branch on 7th August:—

Gardening is one of the most pleasant and healthful hobbies that a busy housewife can possibly have. To spend an occasional half-hour or so on a pleasant sunny day among the flowers when one is weary of indoor work is most restful and soothing. A well-cared-for flower garden always gives a home-like atmosphere to a house, and one is well repaid for the work spent.

The rose is considered the queen of all flowers, and there are many beautiful new varieties of standards to be had. July is considered the correct month to prune roses, and if the prunings are planted in a trench and well watered for the first year some very nice rose bushes will be obtained.

The purple Iris is very popular for indoor decoration at this time of the year, when there are so few flowers to be had. Its correct name is Iris Stylosa, and it can be had in several shades. They do not flower the year following re-planting, but after that they bloom well, and one can always be sure of a dainty vase of flowers for the tables during the winter months.

Seeds of spring flowering annuals should be sown early in this climate. Pansy and Viola seed should be sown in January, in order to have strong plants ready to put out with the first rains, and they then make good growth while the weather is warm. My experience with seedlings is that it is quite useless to plant out while the ground is sodden and cold. They frequently damp off and die right away, whereas, if planted early, they may appear at a standstill during the winter months, but still they have a good root system, and with the appearance of the warmer spring days they go ahead rapidly.

Firstly, a garden should be carefully planned and laid out in shaped beds, bordered preferably with a neat design of flat stones, then small bordering plants, such as the popular Viola, Phlox, Virginian Stocks, Violets, Portulacca, &c.; in fact, any small, close-flowering plants which make an attractive setting for the larger flowers. A popular idea which gives a nice finish to a small garden is a herbaceous border, on either side of the lay-out of small beds. This is a long bed, planted firstly with small edging plants, then flowers a little larger, ranging up to the tall varieties, such as Foxgloves, Delphiniums, Hollyhocks, &c., as a background, and then behind this, if there is space to spare, several of the larger flowering shrubs may be planted. This gives a sheltered appearance to a garden, and there is usually a show of flowers, as a variety of shrubs are to be had which give a succession of blooms.

No garden is complete without a collection of bulbs. Even the humble yellow and white Jonquil brightens our flower beds during dull winter days, and they look most attractive if planted beneath trees and shrubs. The little Snowdrop is also a first favourite, and then we have Daffodils, Freesias (which have such a sweet perfume), Hyacinths of various colours, and others too numerous to mention. The Arum Lilies and Agapanthus also should have a place, as they look very stately and beautiful against a background of trees. To have a really beautiful and attractive flower garden, it is necessary to have a plentiful supply of water during the summer months. This, with care and attention during the winter months, such as hoeing cultivating and manuring, should ensure a beautiful flower garden that any home may be proud of. (Secretary, Mrs. W. Bignell.)

[Paper read by Mrs. OSWALD at a meeting of the Maltee Branch on 8th August.]

Flowers to be sown in January and February are Iceland poppies, Cinerarias, Pansies, Stocks, Lupins; also Gladioli bulbs to flower in autumn weather, and Violas are extremely showy as a border. Lupins provide a great quantity of flowers for cutting and should be sown in their permanent position as they do not transplant well.

When raising Iceland poppies choose a cool shady spot and keep the bed covered with hessian until the seeds have germinated.

March is the best time for Sweet Peas, for which the ground should be deeply dug and plenty of rotted manure used. Antirrhinums require a fairly dry, not over rich soil. Carnations like a gritty soil. This also is the month for spring flowering bulbs, such as Daffodils, Tulips, and Freesias.

In April flowers for spring blooming not already sown should be put in without delay. Seedlings previously raised should be planted out as soon as they are large enough. Choose dull weather, and wet the ground around the roots thoroughly before planting. This is an ideal month for planting roses, evergreen shrubs, strawberries, and Violets. The soil for Violets should not be too rich.

In May Cannas and Chrysanthemums may be lifted. Dahlias may be lifted also and kept in a dry place until spring. During June and July prune roses and fruit trees, Geraniums should be pruned to induce fresh growth, in order to make them flower freely. Winter pruning of roses should be completed during July, in other than cold districts. In heavy soil a dressing of lime will be of benefit. Well rotted stable manure can be forked into soil around trees and shrubs.

August and September.—Cannas thrive in heavy rich damp soil. Phlox should be divided if too thick. Liquid manures should be applied to Violas. Sow Mignonette seeds where it is to grow, as it does not transplant well. As Chrysanthemums throw up their new shoots break them off at the base and strike them in a warm, moist, sandy soil. These make better flowering plants than the old clumps.

Phlox are one of the finest bedding plants for coloured masses during summer months. For Geraniums choose a soil neither rich nor too moist, otherwise they do not flower freely.

Petunias, Portulacca, and Zinnias should be planted during October. Portulacca flowers well during the hottest weather, and is very attractive where grown along brick paths.

November and December:—French Marigolds flower well in the summer. Asters need a shady spot. Daffodil and Freesia bulbs may be lifted during these months as they die back. From this time onwards, early sowing of Stocks, Iceland Poppies and Pansies is frequently made.

Dahlias do well if planted at this season.

Most soil is improved by the addition of manure, and for most plants plenty of water is essential. (Secretary—Miss L. Bassham.)

ESA BLUESTONE
MANUFACTURED BY
THE ELECTROLYTIC REFINING AND SMELTING COMPANY OF AUSTRALIA LIMITED, PORT KEMBLA, N.S.W.

KNITTED SOCKS.

[Paper by Mrs. L. M. MARTIN read at a meeting of the Maltee Branch on 13th June.]

For knitting socks I always use either 3-ply or 4-ply Paton and Baldwin's Superfingering wool. I prefer the 3-ply as the socks are much softer and look better. Cast on 72 stitches, 24 on each needle, and knit in ribbing. Knit 1 purl 1 for 4ins., then knit 1½ins. in plain knitting, except 1 stitch for the back of leg which is purled right down to the heel. In next row start to shape the leg by knitting 2 stitches together either side of the purl at the back of the leg. Then knit 1¼ins. then decrease again in the same, knit 1in. and decrease, each time knitting less before decreasing until 12 stitches have been taken off, leaving 60. Knit ½in. plain, then start the heel. With 30 stitches on back needle and 15 on each of the others knit a double heel by slipping 1 stitch, knitting 1 stitch across the 30 stitches and purling back for 15 to 20 rows, according to length required. Then turn the heel. Slip 1, knit 18, slip 1, knit 1, pass the slipped stitch over, turn slip 1, purl 7, purl 2 together, turn; slip 1, knit 8, slip 1, knit 1, pass the slipped stitch over, turn; slip 1, purl 9, purl 2 together, turn; slip 1, knit 10, slip 1, knit 1, pass the slipped stitch over, turn; slip 1, purl 11, purl 2 together, turn; continue to work in this manner until 18 stitches are on the needle, then knit 16 or 17 stitches on the side of the heel, and across the 30 stitches on the instep. Knit the other 16 or 17 stitches on the other side of the heel, then knit 2 plain rows all around on the three needles. Next row commence shaping the foot. Knit down the first of the back needles to the last three stitches, slip 1, knit 1, pass the slipped stitch over, knit 1 then knit the 30 instep stitches, knit 1, slip 1, knit 1, pass the slipped stitch over, then knit on to the end of the needle plain. Knit 2 rounds plain then decrease again, in the same way. Then 2 rounds plain again. Continue this until you have 15 stitches on each back needle and 30 stitches on the front. Knit plain without decreasing the length you require for the foot. From the side of heel, measurements are:—6in. for a 10in. foot, 6½in. for a 10½in. foot, 7in. for a 11in. foot. To shape the toe:—First needle, knit plain to the last 3 stitches. Slip 1, knit 1, pass slipped stitch over. Knit 1. Front needle, knit 1, slip 1, knit 1, pass slipped stitch over. Knit to last 3 stitches. Slip 1, knit 1, pass slipped stitch over, knit 1; third needle, knit 1, slip 1, pass slipped stitch over, knit plain to end of needle; 2nd and 3rd rounds plain, then decrease in same way again and continue the decreasing thus until there are 6 stitches on each of the 2 back needles and 12 stiches on the front one. Put the back stiches on one needle so as to have the work on 2 needles, then break your wool about 12 inches from the work. Thread the wool to a darning needle and graft off as if for knitting, into the first stitch of the front needle. Draw it through and slip the latter off the needle. Insert the needle as if for purling into the second stitch of the front needle, draw the wool through and let the stitch remain on the needle, taking the wool under the front needle, and insert the darning needle as for purling into the first stitch of the back needle. Draw wool through this stitch and draw the latter off the needle. Inserting the wool needle as if for knitting into the second stitch on the back needle, draw the wool through and let the stitch remain on the needle. Bring the wool forward under the needle and repeat until all the stitches are worked off, darning in the end of the wool securely when finished. (Secretary, Miss L. Bassham.)

THE SOCIAL ASPECT OF FARM LIFE.

[Paper given by Mrs. N. J. CROSS on 4th July, 1935, at a meeting of the Boor's Plains Branch.]

Farmer's wives, or any women that live in the country enjoy very little social life in comparison to our city sisters, particularly since the depression. The difficult times we are passing through has affected the women on farms to a considerable extent.

In order to balance the budget one has to scheme in different ways. For instance, during the last few years many of the farm women have begun to bake their own bread, and to keep extra cows and poultry, which all means extra work, thereby leaving less time for pleasures, etc.

Although one always enjoys an outing or a social gathering of this kind, there seems very little time to devote to pleasures of any kind and often one feels too fatigued to make the effort to go out to a social gathering. We sometimes become too absorbed in our daily routine of work, so that we leave very little time to relax from the strain of our daily round and obtain any pleasure of the various ways wherewith to make out life on the farm brighter in the social way. With meetings of the Agricultural Bureau, ladies from the different districts can meet and discuss subjects that are of interest to all women, and as time goes on and we all become more confident in public speaking and are not so afraid of our own voices. The criticisms and discussions enable all members to enjoy these social gatherings.

Another social gathering I would suggest is an afternoon given in one's own home, where one can invite friends and entertain them with competitions and games, or failing that, the idea of coming together and enjoying a social chat with one's neighbours and friends over a cup of tea followed by a stroll around the garden or grounds always proves to be enjoyable and the pleasure derived from such an afternoon amply rewards one for any small effort that may have been made. An afternoon spent on the tennis court is always enjoyed by ladies and young girls and does not require much preparation. The women of to-day are inclined to overdo this preparation of afternoon tea; I would suggest a cup of tea with scones, small cakes, and perhaps a plain cake or so, as it seems unnecessary to tire oneself with a lot of cooking before friends arrive. Not being in doors during the afternoon the house will be sufficiently clean from the usual week end cleaning, therefore there is no need for any extra preparation in that way. This form of entertaining helps to keep one young and healthy, and the benefit derived from such exercise is of great value to one physically as well as socially.

One always enjoys an evening given in one's own home with just a few friends and some music and songs and elocutionary items if the friends happen to be talented in that way. It is also an opportunity for the children to perform in the presence of others, thereby being a great help to them later when they may be called to assist at a school concert or any other public function.

Table tennis or bagetelle always affords a good deal of pleasure to both old and young, followed by supper. Bridge afternoons and evenings are very popular too. Besides entertainments given in the home we must not forget the enjoyable evenings spent at social gatherings, not forgetting the Bureau social. In the summer we have the sea to call us to come and enjoy the cool breezes and the bathing.

Endeavour to make life on the farm as pleasant and attractive as possible, not only for ourselves, but also for young people, as life in the country is far different from the many pleasures the young people enjoy in the city, besides work being much harder for them. (Secretary, Miss L. Stanway.)

REARING OF TURKEYS.

[Paper read by Mrs. R. O. PHILLIS at a meeting of the Karte Branch on 14th August.]

Turkeys can be reared successfully in this district, but they need a lot of attention, especially in the feeding and housing or yards.

I started my first lot by putting 9 eggs under a Black Orpington fowl, and she hatched 7 chicks. I kept them isolated from all other fowls, which is one of the main points in rearing of young turkeys until they reach a certain age, which I call "red head" stage. Young turkeys should not be fed until they are 24 hours old. The first meal should consist of hard-boiled egg chopped very finely. As they grow older add a little chopped lucerne or lettuce. Some people advise onion, but it is better left out. When they are about a week or so old give them curdled milk and bran, but not

pollard, as pollard binds them, and if this is not attended to when first noticed you are apt to lose all your batch of young birds. Crushed wheat is more digestible than whole wheat until they are six to eight weeks old.

Members of the recently formed Women's Branch at Karte.

Breeding.—To obtain good results you need only six hens for one gobbler; otherwise you will have too many infertile eggs. When the hens start laying let them keep their own nests until they go broody and they can then be moved to a suitable place without any trouble. A turkey egg takes a calendar month (30-31 days) to hatch. I have heard several people say the eggs were no good when the bird sat for just four weeks and they have thrown her off the nest by not knowing how long they should set. A turkey is better set out in the open where there is a good deal of dampness. They start to lay and sit from July to January. I have had them bring out a batch and when they are about 5 to 6 weeks old they are laying again. Change your gobbler every year. If keeping any of the young hens from last year's batch, never breed back, as it causes many losses. Obtain one if possible from another district. Turkeys do not need a shed, they are better roosting out in the open. Fresh air is a main point. Do not close them in a shed with fowls or other birds. Fowl lice and tick are very bad on turkeys, and will kill them very quickly. (Secretary, Mrs. F. N. Atze.)

BREAD-MAKING.

[Paper by Mrs. A. ADAMS, read at a meeting of the Boor's Plains Branch on 1st August.]

During the past few years incomes have lessened considerably, this being caused by the low prices received for our wheat and other things produced on the farm; and there are few of us who have not found it necessary to economise in every possible way, in order to help our men folk to meet the needs of the present time. Many women have decided to help by making their own bread, it being one of the most important food items that we need. It is very nice to have the baker call twice or three times a week, but when one thinks of the price we are asked to pay for a loaf of bread and the price we receive for our wheat, we realise that it is too great a difference and so we set about making our own bread. It costs very little to have our own wheat milled and we can get enough to last several months, which I think is the better plan as the older flour makes the best bread.

First of all we need a deep pan for mixing the bread in, and this pan is best if never washed; it can be scraped and then rubbed clean with a dry towel, the same applying to the tins in which the bread is baked. There are many different kinds of yeast, and many different methods of making yeast. I make hop-yeast in the following way:—Put a large pinch of hops into a jug and pour over them one pint of boiling water in which a potato has been boiled. When cold pour into a bottle and add 1 tablespoon of sugar and flour mixed together with a little cold water. Add a small pinch of cream of tartar, shake well, and leave in a warm place to work. It should be ready in four hours. This quantity will make four average size loaves and five sifters of flour will be needed. Sift the flour into the mixing pan and allow 1 teaspoon of salt to each sifter of flour. Warm the flour for a few minutes, then add yeast and sufficient luke-warm water to mix (do not have dough too stiff). Knead for a few minutes, cover well with a blanket and leave over night to rise. Next morning it should be ready to knead up again and shape into loaves. Put aside the loaves to rise again, and in about an hour they will be ready to bake.

I have been using compressed yeast about eight months now, and find it a much quicker method of bread making, as it does not need to be mixed over night. I think that the time saved in this way makes up for the little extra cost.

One ounce of compressed yeast will make four loaves of bread. Sift flour and put the salt in the bottom of the pan and then warm. Take the yeast and break up finely in a small basin with a fork, add about 1 cup of luke-warm water and mix well. Make a hole in the centre of the warm flour, pour in the yeast, leave about 20 minutes in a warm place so the yeast will work a little, sprinkle about 2 dessertspoons of sugar on the flour around the yeast being careful not to put any sugar in the yeast. Now proceed to mix the bread in the usual way as with hop yeast. This will not need so much kneading as the hop yeast bread.

Open the oven door and lay on it several thicknesses of paper. Put pan containing dough on this and cover with more paper; this will only take about 3 hours to rise, and if mixed after breakfast it will be baked by mid-day. If it is not convenient to set the dough on the oven door it can be put on a chair close to the stove, but it will take a little longer to rise.

An ounce of compressed yeast costs 3d. and will keep if kept in a cool place. Now there is not only the mixing of the bread and putting it in the tins, but like most other things it has to be baked, and the baking is a very important process. The oven should be hot—about the heat used for baking pastry—and 10 minutes after the bread is in the oven it should have a nice golden brown crust, and it should be cooked in an hour and a quarter. It is most important not to let the dough get cold at any time, as this will result in a poor quality loaf. A plate warmed and placed up-side down on top of the dough helps it to rise more quickly. Sometimes the bread is coarse; this is usually caused by over rising of the dough. The flour should be kept in a dry place free from any foreign odours such as onions, etc. (Secretary, Miss L. Stanway).

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Angaston, Saturday, 29th February.
Mundalla, Wednesday, 4th March.
Mount Pleasant, Thursday, 19th March.

Agricultural Bureau Conferences, 1936.

River Murray (Swamps), at Wood's Point, Thursday, 20th February (Mr. F. P. Baily, The Point, Secretary).

Lower North, at Owen, Thursday, 27th February (Mr. A. Helps, Owen, Secretary).

Yorke Peninsula, at Arthurton, Wednesday, 4th March (Mr. T. H. Howlett, Box 8, Moonta, Secretary).

Mid North, at Beetaloo Valley, Thursday, 12th March (Mr. B. W. Giddings, Beetaloo Valley, Secretary).

South-East (Upper), at Bordertown, Wednesday, 1st April (Mr. L. H. Butler, Secretary).

South-East (Lower), at Kybybolite, Wednesday, 8th April (Mr. A. S. Shepherd, Kybybolite. Secretary).

Dairying, at Strathalbyn, Thursday, 21st April (Mr. Reg. Sissons, Strathalbyn, Secretary).

River Murray, at Block E, Thursday, 18th June (Mr. J. C. K. Brigham, Box 65, Renmark, Secretary).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Ration for Dairy Cattle from Farm Produce.

Replying to the Secretary of the Brimpton Lake Branch of the Agricultural Bureau, who asked:—"Can a suitable ration for milking cows be made from grains produced on the farm, wheat, oats, and barley; if so, what quantity of each should be used, and what quantity of the whole should be fed per lb. of milk produced; it is intended to crush the grain?" Mr. H. B. Barlow (Chief Dairy Instructor) said oats and barley in a crushed state make an excellent base for a concentrate mixture for dairy cows. If oats or barley are not available, crushed wheat can be used, but it is rather deficient in protein and high in carbo-hydrates. Pinched wheat is a much better feed for dairy cows than plump wheat.

A more or less ideal concentrate food would be a mixture of 100lbs. bran, 100lbs. crushed oats or barley, or a mixture of both, and 30lbs. of linseed meal, fed at the rate of 1lb. of the mixture for each 3lbs. to 4lbs. of milk given.

If any green stuff or ensilage is available, the bran is not essential. If green lucerne is available in any quantity, the linseed meal can be done without, except when maximum returns are required. This also applies when lucerne chaff forms the bulk ration in place of cereal chaff. Both wheaten and oaten chaff are much more valuable for dairy cows when cut on the green side.

If only cereal chaff and grains are available, feed as much chaff as the cow will clean up comfortably, with the crushed grain ration at the rate suggested. In addition, it is very essential to add to the feed a mineral mixture at the rate of 2ozs. to 4ozs. per cow per day. A mixture of bone meal and salt, or dicalcic phosphate and salt, or superphosphate and salt in equal proportions, will make a satisfactory mineral mixture, and is very essential to the health of the cattle. Water should be available at all times, and as much as the cows require.

Aiding Importers of Pedigree Stock.

The introduction of a plan for giving financial assistance to importers of pedigree breeding cattle, sheep, milch goats, and swine from the United Kingdom has recently been announced, following discussions between the Australian Agricultural Council and the Commonwealth Government. The only breeds of swine eligible for assistance will be Berkshire, Large White, Middle White, and Tamworth. The assistance will take the form of a contribution towards expenses incurred in the importation of the animals, but no assistance will be given toward the cost of the animals.

A statement issued by the Department of Commerce says that shipping companies have agreed that in lieu of the freight rates usually charged by them they will charge only out-of-pocket expenses actually incurred by them in provision of stalls, water, &c., and in loading and unloading the animals. The following flat rates have been fixed to cover these out-of-pocket expenses:—Cattle, 30 guineas, including boxes or pens; sheep, 10 guineas, including boxes or pens; milch goats, 10 guineas, including boxes or pens; pigs, 6 guineas, excluding pens. All expenses connected with the transport of the stock from the port of export in the United Kingdom to the port of importation in Australia will be borne in the following proportions:—Two-fifths by the importer, two-fifths by the Commonwealth and State Governments concerned in equal proportions, one-fifth by the Commonwealth Bank, subject to review after 30th June, 1936.

The project will apply only to animals for which a certificate of full registration by a recognised stud society is furnished, together with the vendor's certificate of breeding, and production record, if any. Applications for assistance under the plan, stating the class, breed, age and sex of the animal it is intended to import, the date of shipment, the name of the vessel, and the name of the shipping agent, shall be made by the purchaser of the animal to the Department of Agriculture of the State into which the animal is to be imported. The assistance will apply only if the stock are retained by the purchaser for at least two years from the date of importation.

The importers are required to pay the whole of the expenses connected with the importation of the stock. Shipping charges must be paid in London in sterling, in exchange for bills of lading, as customary. The project will operate in respect of stock shipped from the United Kingdom on or after 1st December, 1935. Arrangements have been made with the State Departments of Agriculture to give the necessary approvals on arrival in Australia of any stock in respect of which it has not been possible to issue a certificate of approval prior to their departure from the United Kingdom.

Production of Butter and Cheese.

The following returns show the production of butter and cheese in South Australia since 1st July, 1935:—

1935.	Butter. lbs.	Cheese. lbs.
July	1,239,452	550,368
August	1,583,330	693,739
September	1,810,860	939,282
October	2,438,672	1,063,195
November	2,109,159	1,061,467

AGRICULTURAL INQUIRIES.

[Replies supplied by W. J. Spafford, Deputy Director of Agriculture.]

"Black-Tip" of Wheat.

The Secretary of the Frayville Branch of the Agricultural Bureau asks:—"If Currawa wheat is badly tipped with black ends, is the wheat fit for use as seed? The sample is good."

Reply—Although the "black-tip" of wheat is often considered to be due to the plant having been affected with a fungus disease, such seed is generally quite safe to use at seeding time.

Milling Tests of Wheat.

"Which is the more important in testing wheat for milling purposes: the Pelshenke test or the dry gluten test?"

Reply—There is no comparison possible between the Pelshenke test for bread-making quality of wheats and the dry gluten content. The former is a test which gives some idea of what the bread-making qualities of wheats are, whereas the other is just a determination of the amount of gluten present in a flour. Sometimes the dry gluten content and the water absorbing power of the flour are taken together to show the strength of a flour, but the only real test is the baking test, wherein loaves of bread made and baked from all flours are compared.

Split Peas.

The Secretary of the Whitwarta Branch of the Agricultural Bureau asks:—"Can Western Australian white peas be made into split peas? If so, how can the average farmer split them? Is it necessary to have expensive machinery to do the work of splitting them?"

Reply—From the meagre amount of information available on the splitting of peas, it appears that there is no doubt about the possibility of using White Brunswick for the purpose, but special machinery is necessary to do the job. To come into the commercial field it would be necessary to get up-to-date machinery, but for household use there is no need to split the peas, and even if this was thought to be necessary, the chances are that the second thresher on a harvester, or some such apparatus, would take sufficient of the skins off to get a supply of split peas.

Phalaris tuberosa.

The Balhannah Agricultural Bureau asks, "What time of the year should Phalaris tuberosa *seed be sown in Balhannah district?"*

Reply—In the Balhannah district *Phalaris tuberosa* should be seeded in the autumn; in April if the land is in good germinating condition, but otherwise in May. It is very important that the land should be clean and free from weeds, and it is advisable to fallow the land, even if for a short period only, before attempting to establish the crop. *Phalaris* seed should not be mixed with other seed in ordinary conditions, and if a mixed pasture is desired, the other plants can be introduced after the *Phalaris* is one or two years old.

If the germinating test has shown the *Phalaris* seed to have a high germinating power, from 2lbs. to 4lbs. of seed per acre is ample. The seed can be mixed with superphosphate provided that it is sown not more than 4 hours after mixing.

Phalaris tuberosa can be cut with mower or scythe, and is a really good green fodder. In strong-growing stands the growth becomes so dense that it is a fairly heavy job cutting it, but it can be done without much trouble in most cases. Provided the hay is not left out in the fields too long after it has been cured as hay, it makes a good hay and is quite suitable for feeding to cows after being chaffed.

Oats for 16-25in. Rainfall Districts.

The Blackheath Agricultural Bureau asks, "Which is the best variety of oats to grow for grazing purposes in a district with a rainfall of 16*in. to* 25*in.?"*

Reply—"Mulga" is a good oat to grow for grazing purposes in a district where the annual rainfall might reach 25in. If to be grown for grazing only, better results would be secured from a mixture of about 30lbs. rye and 40lbs. oats per acre; the rye producing winter feed in greater abundance than will any other cereal and the oats continuing to grow well into the summer.

HORTICULTURAL INQUIRIES.

Pear Leaf Blister Mite.

Specimens of leaves of a pear tree, showing signs of insect attack, were forwarded to the Department of Agriculture for identification by a subscriber to the *Journal of Agriculture* at Mundalla. Mr. A. G. Strickland, M.Sc., Chief Horticultural Instructor, in reply to the inquiry, says the pear leaves have been subjected to attack by the pear leaf blister mite (*Eriophyes pyri*, Pagen). This mite is a very small creature, about one-hundredth of an inch in length, and passes the winter beneath bud scales. When buds commence to swell in the spring the over-wintering mites lay eggs on the under surface of unfolding leaves. The eggs hatch under the protection of the opening buds, and the young larvae burrow into leaves and set up irritation, which results in the development of small green blisters on the leaf surfaces. When the mites are fully grown they leave the blisters in which they have developed, and infest new leaves as they appear. The pest is fairly easily controlled by application of a strong lime sulphur spray (1gall. of lime sulphur concentrate in 10-15galls. of water) just before buds swell in spring. This strong spray should *not* be applied after bud movement has commenced.

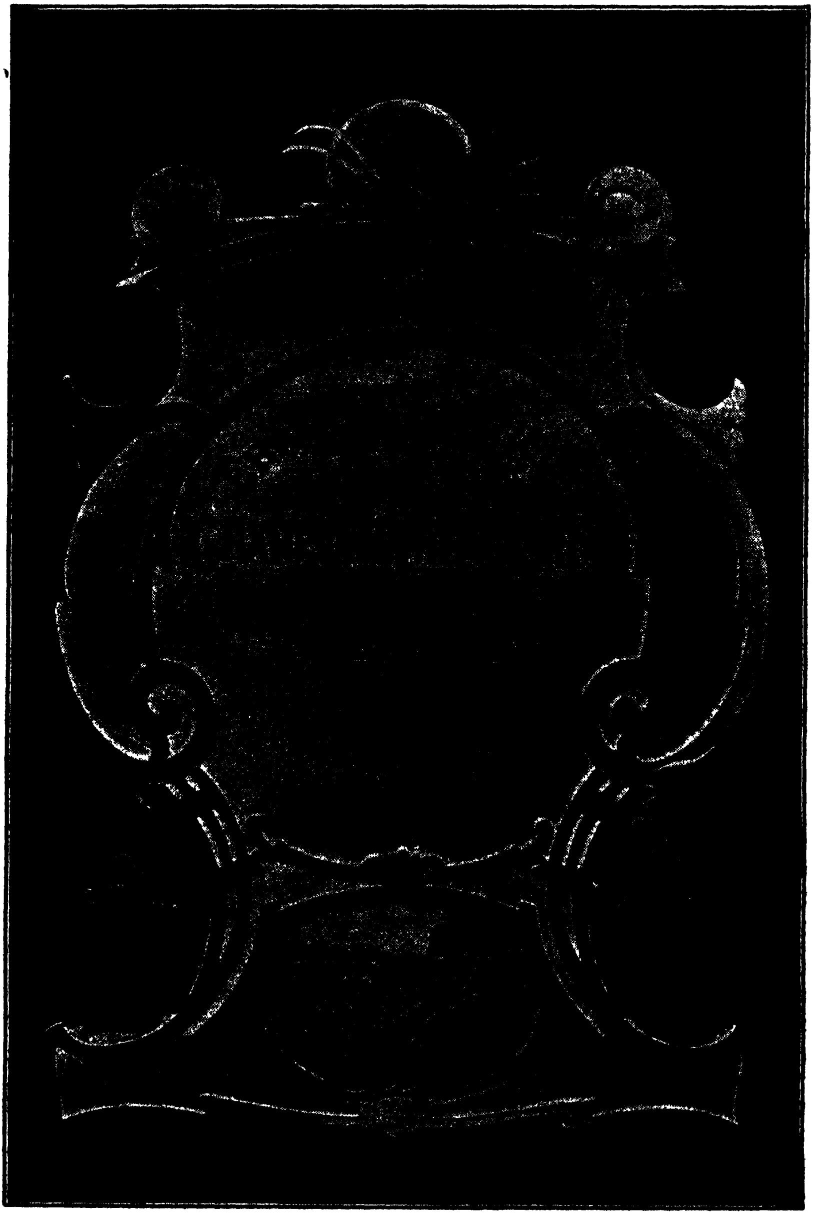
THE CHAMPIONSHIP WHEAT CROP COMPETITION.

(WON BY MR. W. H. WATKINS, YEELANNA.)

In his report on the Championship Wheat Crop Competition for the 1935-36 season, Mr. W. J. Spafford (Deputy Director of Agriculture) who judged the entries, states that Wheat Crop Competitions supervised by the Department of Agriculture have been conducted in South Australia for 12 years.

For the first six seasons, financial assistance was given by the Government, but unfortunately in 1931 and 1932 it was found necessary to discontinue the granting of this subsidy. However, in the following year a generous donation by the South Australian Farmers' Co-operative Union Limited materially assisted in the success of the Competitions, whilst for the past two seasons, the Government subsidy has been renewed. The help thus given has been a very big factor in maintaining interest in the Crop Competitions during the period of depression and the low price of wheat.

The wheat growing season of 1935-36 was notable for the very great difference in the crops grown in the districts recognised as good wheat growing districts, and those a little on the dry side. In the former case, really good yields were received, whereas in the lower rainfall places, crops were from fair to poor. Throughout the State the quality of the grain was really high, and in many cases this was so much so that considerably greater yields were received than were anticipated before the harvesting machines were started in the crops.



Wheat Crop Competitions were conducted in 19 districts, and the number of crops entered in these totalled 407. The judges appointed by the Department of Agriculture inspected all of the crops, and issued reports on each District Competition. Of the first prize winners of the District Competitions, the judges considered that 15 of them were sufficiently good to be inspected in the Championship Competition.

Table Showing Progress of Wheat Crop Competitions.

Year.	Districts Conducting Competitions.	Number of Crops Exhibited.
1924	12	290
1925	13	248
1926	17	444
1927	19	525
1928	22	634
1929	21	520
1930	19	473
1931	16	352
1932	20	385
1933	19	351
1934	18	328
1935	19	407

In 1927 the Royal Agricultural and Horticultural Society offered as a prize in connection with Wheat Crop Competitions conducted under the auspices of the Department of Agriculture, a Silver Challenge Shield of the value of 50 guineas, and annually a small replica of the Shield valued at 5 guineas.

The Royal Society desired specially to encourage the Wheat Crop Competitions, and in accepting the generous offer, the Government agreed to the conditions laid down by the Society, which were as follows:—

1. The prizes go to the person exhibiting the best crop in the Competition supervised by the Department of Agriculture, the Silver Challenge Shield to be held for a period of 12 months immediately succeeding the award, and the silver replica to become the absolute property of the winner.
2. The Challenge Shield, with the name of each year's winner engraved thereon, to be exhibited in the Town Hall or Institute nearest the farm on which the winning crop was grown.
3. The crop awarded first prize in each supervised District Competition to be taken as an entry for the Championship Competition, except in any case in which it is thought by the judge of the District Competition that the winning crop is not of sufficient merit to warrant inspection for the Championship trophy.
4. All entres for the Championship to be inspected by one judge. Such inspection to be undertaken in each district soon after the district judge has made his awards, but not before the crop has ripened.
5. Each competitor for the Championship to be required to stage one bag of grain and one sheaf (about 1ft. in diameter) of grain in the straw at the Royal Spring Show following the competition.

WINNERS OF THE CHAMPIONSHIP WHEAT CROP.

1927.	F. V. Trenorden, Bordertown. (Federation wheat.)
1928.	F. Coleman, Saddleworth. (Leak's Rustproof and Fondling Wheat.)
1929.	F. V. Trenorden, Bordertown. (Bena wheat.)
1930.	H. C. M. Pilgrim, Wolseley. (Gallipoli wheat.)
1931.	A. M. Dawkins, Gawler River. (Ford wheat.)
1932.	J. P. Carrigg, Hamley Bridge.. (Sword wheat)
1933.	H. Michael, Hilltown. (Dan wheat.)
1934.	P. McD. Smyth, Salter's Springs. (Sword wheat.)
1935.	W. H. Watkins, Yeelanna. (Sword wheat.)

· THE ENTRIES.

Because four of the fifteen entries in the Championship Competition contained two varieties, there were nineteen plots of wheat inspected, and of these 8 were of Sword, 4 of Ford, 2 of Ranee, and one each of Nabawa, Dan, Gallipoli, Aussie, and Geeralying. With one exception, all of the wheat was of good quality, being full, bright, and shotty, and obviously of heavy bushel weight. As is general in years of good quality grain, there was a general tendency to shed grain, but this weakness was really serious in one case only, although in some other cases it was easily noticeable and must have lowered the returns from the crops. So many of the crops appeared as though they would return about the same yield per acre as one another, that the placings of the entries into their order of merit depended upon the points allotted for good farming rather than for yield. The crops were of such general excellence that it was a particular pleasure to judge the competition this season.

THE AWARDS.

In reporting on the entries it has been decided to follow the practice of other years of indicating the crops which would have been placed second, and third to the winner of the Championship trophy, had this been an ordinary Competition, but the remaining crops are not shown in order of merit, and where any remarks are made on their crops, the exhibitors' names are placed in alphabetical order, and not according to points awarded. The awards, and a brief description of the crops submitted in the Competition, are set out below:—

CHAMPIONSHIP WHEAT CROP (SWORD).

W. H. Watkins, Yeelanna.

The Flinders Wheat Crop Competition was won by Mr. Watkins with this very nice crop of Sword wheat, which was afterwards adjudged the best crop submitted in the Championship Competition. Despite the fact that it was shedding badly, it was still a heavy-yielding crop, and had few other weaknesses as a Competition crop, except a few patches where Red Rust had done a little damage, and being old-type Sword, it was not all of one kind.

The land on which the crop was grown carried a wheat crop on fallow in 1931, was then left out as pasture for a year, grew an oat crop, and was fallowed for the 1935-36 crop. During the fallowing period the land was well worked, the ploughing being done in August after which it was harrowed in September, cultivated in October, cultipacked in January, cultivated in March, and harrowed and cultivated in May. On 6th and 7th June, Sword wheat at the rate of 70lbs. of graded and "dry" pickled seed was drilled in with a combine, together with 120lbs. of superphosphate per acre, and the whole field was then harrowed.

The thorough and careful soil working showed its effect in the crop, for it was as nearly free from weeds as it is possible to imagine a wheat crop grown under ordinary field conditions. A few isolated Wild Oat plants were present, but even these were most difficult to find. There had been just a little Spotted Rust on the flag of most plants, and a few patches had developed Red Rust, but the damage done on these small areas was little indeed. The wheat was typical old-time Sword, and as such was not as true to type as is desired, and, as is usual with this strain of Sword, contained some brown chaffed wheat and a few bearded plants. The drilling of the crop had been carried out very well, drill-misses being almost non-existent. The appearance of parts of the crop was lowered by patches that had been washed out or drowned out, but such acts of Providence do not affect the Competition value of the crop.

Everything about this very attractive crop—particularly the almost complete freedom from weeds—showed evidence of good farming practices, and Mr. Watkins is entitled to full credit for growing the Championship Crop by intelligent methods in which luck played no part.

R. L. Sluggett, Hilltown (Dan).

With this nice crop of Dan wheat Mr. Sluggett won the Midlands District Competition, and scored well in the Championship Competition. The land on which it was grown had been cropped heavily with wheat, and for years the rotation practised on this field had been the simple one of bare fallow-wheat-bare fallow-wheat. The fallow was prepared by ploughing in July, harrowing in September, and cultivating in October and April. During the second week in June, 90lbs. of graded and dry pickled wheat were drilled in with a combine with 90lbs. of superphosphate (45 per cent.) per acre.

A lot of Wild Oats were found throughout the crop, but other than this weed, the crop was clean. No evidence of diseases could be seen. There was a noticeable amount of admixture of other kinds in this crop, so that it could only be classed as fairly true to type. The drilling of the crop was really good, and any irregularity was due to the presence of "red" land in the field, on which the yield would be considerably lower than from the bulk of the crop, which was grown on more friable soil. Some of the heavy patches of crop had lodged rather badly. This heavy-yielding crop was an attractive Competition Crop, but was a little irregular and rather badly fouled with Wild Oats.

L. Wachtel, Palmer (Sword and Ranee).

With 30 acres of Sword and 20 acres of Ranee, the first prize in the Southern District Wheat Crop Competition was secured by Mr. Wachtel. The rotation of cropping under which the field had been worked for many years was the three-course one of fallow-wheat-pasture, and on the appearance of the crop, was a very suitable one, for the soil was obviously in good heart. The ploughing was done with a mould-board plough in July, and the furrow slice broken down in August with harrow, and from then on the cultivator or harrows were used when required. On 25th April seeding was carried out with a combine, using 71lbs. of graded and "dry" pickled seed, with 100lbs superphosphate (48 per cent.) per acre.

The crops were almost weed-free, there being just an isolated plant of Wild Oats in Sword, and a couple of Barley plants in Ranee as well. Sword showed a little Loose Smut, and odd plants affected with Flag Smut were seen in Ranee. Both varieties were fairly true to type, but showed some admixture of other kinds. The whole crop was remarkably well-drilled for the hilliness of the country, and was very even. Sword was shedding a little by harvest time.

This entry was an attractive Competition crop, exceptionally free from weeds, and extremely even and regular considering that it was grown on very hilly country, but was not such a heavy-yielding crop as some other entries. The farming practices of Mr. Wachtel are good, for the land has been kept in good heart, and cultivation is so thorough as to keep down weeds.

OTHER ENTRIES.

(In Alphabetical Order.)

W. Adams, Jamestown (Ranee).

This crop, which was grown on the farm of the Misses McLeod of Jamestown, won the Northern District Wheat Crop Competition, and was a fairly even crop of Ranee, but hardly heavy enough to win a State Championship. It was very clean, so far as weeds were concerned, except that there was a sprinkling of

Barley throughout, and odd plants of Wild Oats and Poppies as well as a little Hoary Cress. Loose Smut had been bad, there was just a little Flag Smut, and 3 or 4 very small patches affected with Take-all were located. Fairly true to type, and although there were a few drill misses here and there, it was an even and regular crop.

N. Boundy, Minlaton (Ford).

The four-course rotation of cropping of fallow-wheat-barley-pasture, is followed in the field which grew the crop of Ford which won the Southern Yorke Peninsula Crop Competition. The land was ploughed and harrowed in July, cultivated and harrowed in each of the months of August, September, March, and May. On 24th June a combine was used to sow 75lbs. of formalin-pickled seed with 90lbs. of superphosphate per acre.

Despite all the cultivation work put into the fallow, the crop was not really clean, for there was a lot of Charlock, Poppies, and Wild Oats in patches, a little King Island Melilot, and a few plants of Soapwort and Wild Mignonette. There were no signs of disease of any kind. The crop was of the old-time Ford, and was not particularly true to type, but was fair in this regard. Drilling was well done, and any patchiness present was due to weeds. The crop was shedding a fair amount of grain.

E. J. Buckley, Bordertown (Gallipoli).

The land on which Mr. Buckley grew the wheat crop which won the Tatiara Crop Competition had been left out as pasture for several years before being fallowed in 1934. The ploughing of the fallow was done in July, and it was harrowed twice in August, cultivated in September, October, and November, harrowed in March, and cultivated in April. At the end of May 70lbs. of graded and "dry" pickled seed were sown with 90lbs. of superphosphate per acre, and the land was immediately harrowed.

At seeding time Wimmera Rye grass seed was put in with the wheat, and this grass was thick and strong throughout the crop. There was also a lot of Wild Oats and some Canary Grass, Slender Thistle, and Poppies, so even without the Rye grass the crop was only fairly clean. There had been some Spotted Rust, and the later plants were carrying just a little Red Rust. So far as trueness to type was concerned, the crop was quite good, there being only a very light sprinkling of other kinds in it. Drilling was good, but the crop was very irregular, being drowned out in patches.

P. P. Cook, Mt. Damper (Ford).

No set rotation of cropping had been followed by Mr. Cook, but of recent years the field which carried the winning crop in the Le Hunte District Crop Competition had been treated as follows:—1930 fallow, 1931 wheat, 1932 pasture, 1933 oats, and 1934 fallow. The fallow was ploughed in July, cultivated in September and cultivated and harrowed in April. On 5th May seeding was carried out with a disc drill, when 55lbs. of graded and "dry" pickled seed and 90lbs. superphosphate (45 per cent.) were sown per acre.

The fallow received too little work to control all weeds, for there were some Sheepweed, Poppies, Wild Mustard, odd plants of Wild Oats, and a few Barley plants. There were signs of Spotted Rust having appeared, but no other diseases were seen. The crop was of old-type Ford, and carried a light infestation of other kinds. Drilling of the crop was carried out well, and the sample of grain being harvested was really good.

Dawkins and Aunger, Gawler River (Sword).

This entry won the Central District Wheat Competition, and the field which carried it had been worked on the fallow-wheat-oats-fallow rotation of cropping. The ploughing of the fallow was done in August, and it was cultivated in

September, harrowed in October, cultivated and harrowed in May. At the end of May 90lbs. "dry" pickled seed and 90lbs. of superphosphate (45 per cent.) were seeded to the acre, with an ordinary seed drill.

The crop was very clean indeed, there being only odd plants of Wild Mustard, Poppies, and Sheepweed. A little Bunt was found, and there was present just a little Red Rust. There may have been sufficient Rust to flatten the grains slightly, which was noticeable in this crop. Being old-type Sword, the crop showed admixture with other varieties. Drilling was well done, and any irregularity was due to portions of it having lodged fairly badly.

A very attractive Competition crop, except for lack of trueness to type, and the lodging in patches, but despite the latter, it was obviously a heavy-yielding crop.

A. N. & H. M. Freebairn, Owen (Sword).

The rotation of cropping followed in the field which carried the winning crop in the Balaklava District Crop Competition was the three-course one of fallow-wheat-oats. The fallow was ploughed in August, harrowed in September, and cultivated in September, October, November, and early May. In the middle of May a combine was used to sow 70lbs. of graded and "dry" pickled seed and 155lbs. of superphosphate (48 per cent.) per acre.

This crop contained only odd plants of Soapwort, Sheepweed, and Wild Mustard, and had a few very small patches of Cape-weed, and was a very clean crop indeed. There was enough Red Rust present on the stalks carrying the lower heads of the later patches to affect the yield and sample of grain, and odd plants had been troubled with Loose Smut. The entry was much nearer true-to-type than most crops of Sword, and was quite nice in this regard. A few misses by the drill were noticeable, but the little unevenness in evidence was due to patches of red soil in the field, where as usual the crop was reduced.

Stan Heinrich, Maitland (Geeralying and Sword).

Mr. Heinrich's crop consisted of 40 acres of Geeralying and 10 acres of Sword, and with it he won the Mid Yorke Peninsula Wheat Crop Competition. The field had been worked for some years on the three-course rotation of cropping of fallow-wheat-barley, and the 1934 fallow was skim-ploughed in September and harrowed, and again harrowed in October. Later in October it was skim-ploughed and harrowed, cultivated in November and again skim-ploughed in May. On 7th and 8th June graded and formalin-pickled seed was sown with a combine at the rate of 65lbs. per acre with 112lbs. of superphosphate (45 per cent.).

The crops were only fairly clean for there was some Wild Mustard, Shepherd's Purse, Catchfly and Poppy, and a little Wild Oats, Barley Grass, Canary Grass, and Soapwort. Geeralying showed just a little Red Rust, but Sword was disease-free. Geeralying was fairly true to type, showing a sprinkling of other kinds, whilst Sword was of the old-type, so only fair in this regard. Drilling was really good, and the crops were nice and even. Geeralying was shedding really badly, and in a season such as 1935-36, when most varieties shed to some extent, the losses from such a wheat must be very heavy.

Martin Bros., Kimba (Ford).

This, the winning crop in the Buxton District Wheat Crop Competition, was grown on land that was left out as pasture for two years, then carried a crop of Oats, and was fallowed before the wheat crop. The land was ploughed in July and cultivated in September, February, and early April. At the end of April 60lbs. of graded seed were sown with a combine, together with 80lbs. superphosphate per acre, and the land was immediately harrowed.

Unfortunately there was a lot of Barley in the crop, otherwise it was fairly clean, there being present a few plants of Wild Mustard, Wild Oats, and Cape Weed. Besides the ordinary weeds, Lucerne and Wimmera Rye grass were found. There appeared to have been a little Spotted Rust on the plants, but other than this, there were no indications of diseases. This crop was of old-type Ford and contained a little admixture of other kinds of wheat. Although the drilling was done fairly well, the crop was somewhat irregular.

E. S. ROSS, Parrakie (Sword).

The Chandos Wheat Crop Competition was won by this crop of Sword wheat, which was produced in a field which had been worked for some time on the three-course rotation of fallow-wheat-pasture. The land was fallowed in June, 1934, and during the third week of May, 1935, was seeded with 60lbs. of seed and 112lbs. of superphosphate per acre.

The crop was nice and clean containing some Wild Mustard and Poppy, and a little Barley grass and Cape-weed. There were no signs of disease of any kind. Some admixture of other varieties was seen, as is usual in old-type Sword. A fair number of small drill misses, but the irregularities were rather those of patchy growth. The crop was shedding a little over most of the area.

W. RYAN, Halbury (Sword).

Mr. Ryan worked the field on which the winning crop in the Mid North District Wheat Crop Competition was grown on the three-course rotation of cropping of fallow-wheat-pasture. The land was fallowed in June, harrowed twice in August and cultivated in September, November, April, and early May. In the third week in May a combine was used to sow 70lbs. of graded and "dry" pickled seed and 150lbs. of superphosphate (48 per cent.) per acre.

Hardly a weed was found in the crop, just odd plants of Wild Oats and Wild Mustard and some patches with Sheepweed. There had been some Spotted Rust and a little Flag Smut and Loose Smut. Seed of old-type Sword was used, so that the crop contained a sprinkling of other varieties. A few drill misses were seen, and about one-quarter of the crop was much lower in height than the remainder. There was some shedding of grain in most parts of the crop.

GORDON SIMS, Cleve (Sword and Nabawa).

With a crop of two varieties of wheat—35 acres of Sword and 15 acres of Nabawa—Mr. Sims secured first prize in the Jervois District Wheat Crop Competition, and the field on which the crops were grown had been farmed on the three-course rotation of cropping of fallow-wheat-Oats. The fallow was ploughed in July and cultivated in September, October, March, and April. Prior to sowing 70lbs. of graded and "dry" pickled seed with 112lbs. superphosphate to the acre, the land was culti-packed, and immediately after seeding, the harrows were put over the land.

The crop was beautifully clean, the only weeds in evidence being odd plants of Wild Mustard and isolated large plants of Cape-weed. A little Red Rust was found on both varieties, but was not serious. Sword was fairly true-to-type, containing some brown-chaffed kind, whilst Nabawa contained only odd plants which were bearded. Drilling was very fair, and although Sword was standing well and yielding good grain, it was shedding a little, whilst Nabawa had lodged in patches, and had some grain bleached in the head.

J. C. WESTBROOK, Arthurton (Ford and Aussie).

The Northern Yorke Peninsula District Wheat Crop Competition was won by this entry, which contained 42 acres of Ford and 8 acres of Aussie. The field in which the crop was grown had been cropped on the three-course rotation of cropping of fallow-wheat-barley, for some time. The 1934 fallow was ploughed in August and cultivated in September, October, March, and April. In the third week in June 90lbs. of graded and formalin-pickled seed were sown with a combine, together with 112lbs. of superphosphate (45 per cent.) per acre.

Besides some Barley in Ford, there were a few plants of Wild Oats and Poppies, whilst the Aussie contained only a few Wild Oat plants. Other than for the presence of such a bad weed as Barley—although not very prevalent—this entry would have been nice and clean. Ford was free from disease, whilst some Flag Smut was noted in Aussie. Ford was a crop of old-type with its admixture of brown-chaffed, bearded and late kinds, but Aussie contained only a few brown-chaffed plants. The crops were well drilled. Ford was shedding a lot, whilst Aussie was more or less matted together, although the crop was not heavy.

ANNUAL REPORT ON PASTURE WORK, KYBYBOLITE, 1934-35.

[By L. J. Cook, R.D.A., Manager.]

(*Continued from page* 780.)

THE BREEDING OF ENGLISH LEICESTER MERINO COMEBACK LAMBS ON SUBTERRANEAN CLOVER AND WIMMERA RYE GRASS PASTURE.

For the past six seasons separate flocks of ewes have been grazed on the different series of fertilised plots, and careful records kept of the lambs produced. The flocks used on these plots in 1934 were constituted as follows:—

	Comebacks.					
	1929. Drop.	1930. Drop.	1931. Drop.	1932. Drop.	1933. Drop.	Total. Drop.
Flock E. grazed on Plots Nos. 4, 5, 6, 15, fertilised with Superphosphate only	19	14	14	9	18	74
Flock I. grazed on Plots Nos. 7, 3, 8, fertilised with Lime or Gypsum and Superphosphate	17	13	12	9	14	65
Flock G. grazed on Plots Nos. 10, 11, and 13, fertilised with Rock Phosphate	13	11	11	7	11	53
Flock KI. Check flock grazed on natural pasture fertilised with Phosphates and Lime	10	4	8	8	21	51

All of the above ewes were born and reared on their respective plots, and are daughters of half-bred English Leicester x Merino ewes by Merino rams. They have known no other type of feed throughout their life.

The following table shows the percentage of lambs marked for the immediate past four seasons from these four flocks:—

Table 15.—*Lambing Percentages of English Leicester Merino Ewes x with Merino Rams, Kybybolite,* 1931-34.

Flocks of Ewes.	Lambs Marked.				Average.	
	1931.	1932.	1933.	1934.		
	%	%	%	%	%	
EA ewes born 1929	80	85	105	116	96	80·5%
EB ewes born 1930	—	80	87	79	82	
EC ewes born 1931	—	—	80	71	76	
ED ewes born 1932	—	—	—	22	22	
IA ewes born 1929	76	65	106	94	85	78·8%
IB ewes born 1930	—	85	100	77	87	
IC ewes born 1931	—	—	54	75	65	
ID ewes born 1932	—	—	—	56	56	
GA ewes born 1929	69	86	108	123	96	85·7%
GB ewes born 1930	—	100	73	109	94	
GC ewes born 1931	—	—	73	73	73	
GD ewes born 1932	—	—	—	43	43	
KIA ewes born 1929	50	75	118	80	81	59·8%
KIB ewes born 1930	—	75	—	75	50	
KIC ewes born 1931	—	—	62	38	50	
KID ewes born 1932	—	—	—	25	25	

The lambs were sired by Merino rams, and the percentages are mostly satisfactory. The 1934 result from the 8-tooth ewes grazing on clover was particularly good, Flock GA marking 123 per cent., and EA 116 per cent., whereas the 2-tooth ewes bred poorly, Flock ED marking only 22 per cent. and KID 25 per cent. Averaging all seasons and ages of ewes, we find that those grazing on Subterranean Clover fertilised with Rock Phosphate have given the highest percentage with 85.7 per cent., those on same pasture fertilised with Superphosphate have given 80.5 per cent., and those on the same fertilised with Lime or Gypsum as well as Superphosphate marked 78.8 per cent., whilst the same age and type of ewes pasturing on well-fertilised natural pasture have only marked 59.8 per cent. This shows a decided advantage in favour of the sown Subterranean Clover pasture, but not a marked difference between the various manurings of this pasture. Considering only the 1929 ewes, in the three flocks on Subterranean Clover pasture, these ewes have averaged 92 per cent. lambs for four seasons, whereas on natural pasture they have average 81 per cent. Similarly the 1930 ewes have averaged 88 per cent. in three seasons on Subterranean Clover, and 50 per cent. on natural pasture; the 1931 ewes have averaged 71 per cent. and 50 per cent. respectively in two seasons; and the 1932 ewes (2-tooths) 40 per cent. on clover, and 25 per cent. on natural pasture. In every case those on the sown pasture have excelled those on natural pasture in breeding. This advantage is due to the greater fertility of ewes grazing on sown pasture, as during the past two seasons a definite record has been kept of the actual number of lambs born in each flock, and the percentage of lamb deaths between birth and marking has been much greater amongst the flocks grazing on sown clover pasture than on natural pasture. For the two seasons the loss on sown pasture has been 18.1 per cent., and that on natural pasture has been 5.6 per cent. Consequently there has been 100 per cent. of births on the former as against 63 per cent. on the latter. This result is no doubt due to the better development and earlier maturity of ewes bred and reared on sown Subterranean Clover pasture.

Regarding the lamb deaths, before marking, amongst the three flocks on sown pasture, these varied amongst the flocks, and when added to the percentages marked, it is shown that there is no significant difference between the number of actual births in these three flocks. Consequently, as yet, no variation in fertility of stock can be traced to the various manurings on this pasture.

The next table shows the average weights of Comeback lambs at weaning time from each flock, and each age of ewe.

TABLE 16.—*Weights of Comeback Lambs at Weaning, Kybybolite,* 1932-35.

Flocks of Ewes.	Weights of Lambs in Pounds.				Average.	
	5/1/32.	17/1/33.	4/1/34.	15/1/35.		
	lbs.	lbs.	lbs.	lbs.	lbs.	
EA ewes born 1929	61·9	65·5	49·8	53·6	57·7	53·7%
EB ewes born 1930	—	64·7	46·9	53·9	55·2	
EC ewes born 1931	—	—	45·6	52·4	49·0	
ED ewes born 1932	—	—	—	53·0	53·0	
IA ewes born 1929	67·0	67·2	46·0	62·8	60·8	55·8%
IB ewes born 1930	—	67·8	45·8	61·8	58·5	
IC ewes born 1931	—	—	39·0	60·7	49·9

Average	62·6	60·9	48·7	53·4	53·1	

Table 16 shows that there has been a considerable variation in weight of lambs from season to season, the 1931 and 1932 drops weighed over 60lbs. each, whereas 1933 drop averaged only 48.7lbs., and this season's 53.4lbs. This is probably a seasonal effect, due to the variation in quality of spring and early summer feed. The heavy November rains of 1933 tended to wash valuable food ingredients from the matured plants, and the somewhat late spring rains of 1934 did not allow for the usual full and complete growth of clover and seed formation. The percentage of clover would appear to be a governing factor. The pastures of the plots fertilised with Rock Phosphate contained a higher proportion of clover than the other plots, and it is perhaps significant that the lambs reared on the former were somewhat heavier at weaning time, namely, 57lbs. on average, as against 56lbs. and 54lbs. on the other clover plots, and only 45lbs. on the natural pasture. More annual grasses with their objectionable seed heads and less clover seed amongst the dry feed had a detrimental effect on the lamb development.

DEVELOPMENT OF COMEBACK EWES ON SUBTERRANEAN CLOVER AND WIMMERA RYE GRASS PASTURE.

The Comeback ewes in the above flocks have been grazed on their respective plots from birth, excepting for a few weeks at weaning and mating times, when they were pastured on similar type of pasture. During each season there has been a marked variation in the rate of development. Each flock has increased in weight during the growing periods of pastures, and decreased during the dry-feed periods. On the sown pasture every season, with all ages of ewes, the development has been greater, and has been maintained better by the ewes throughout their life, than the controls on natural pasture.

Winter growth of *Phalaris tuberosa* and Subterranean Clover pastures grazed and ungrazed.

The 1929 ewes have in their five seasons on the sown pasture averaged 110lbs. live weight, and on the natural pasture 91lbs., a maintained increase of 19lbs. (20.5 per cent.) in live weight in favour of the sown pasture.

The 1930 ewes have in their four seasons on the sown pasture averaged 106lbs., and on the natural pasture 91lbs., an increase of 15lbs. (17 per cent.).

The 1931 ewes have in three seasons on sown pasture averaged 95lbs., and 81lbs. on natural pasture, an increase of 14lbs. (17 per cent.).

The 1932 ewes have in two seasons averaged 94lbs. and 78lbs. respectively, an increase of 16lbs. (21 per cent.), whilst the 1933 ewes for their initial season as hoggets have averaged 80lbs. on sown and 74lbs. on natural pasture, an increase of 6lbs. or 8 per cent.

Collecting all ages together, the ewes on sown pasture for the five seasons show an average greater live weight of 16.8 per cent. than those on well-fertilised natural pasture.

Table 17 shows the details of yearly maximum and minimum live weights attained by each flock each season.

Increase sown over natural pasture		0 14 (11%)		0 12 (9%)		0 8 (6%)		0 15 (12%)		0 1 (1%)

This table shows the average wool production per sheep each season for the life of the sheep grazing on the variously fertilised Subterranean Clover and Wimmera Rye Grass Plots (Flocks G.I.E) compared with Flock KI. that has been bred and reared on top-dressed natural pasture.

The wool production of the flocks on sown pasture this season, 1934-35, was just a little above the average for the immediate past five seasons, whereas that from flock on well-manured natural pasture was much better than usual, equalling, and in some cases exceeding, that produced by ewes on sown pasture.

However, for the five seasons the ewes on clover pasture have averaged 9lbs. wool per head per year, whilst those on natural pasture have averaged 8lbs. 5ozs. per head, a difference of 8 per cent. in favour of sown pasture. The lower section of the Table gives the wool produced per year from the ewes at their respective ages. For five seasons two-tooth ewes on sown pasture have yielded 8lbs. 11ozs. each, 11 per cent. more than on top-dressed natural pasture, which yielded 7lbs. 13ozs. per head. For four seasons four-tooth ewes have yielded 9lbs. 5ozs. each on sown pasture, 9 per cent. more than on natural pasture with 8lbs. 9ozs. per head. For three seasons six-tooth ewes have yielded 9lbs. 3ozs.

each on sown pasture, 6 per cent. better than 8lbs. 11ozs. yielded on natural pasture. For two seasons eight-tooth ewes have produced 9lbs. on clover, and 8lbs. 1oz. on natural pasture 12 per cent. better, and the aged ewes with 8lbs. 11ozs. and 8lbs. 10ozs. respectively have yielded 1 per cent. better. It is, therefore, quite apparent that a sown pasture of Subterranean Clover and Wimmera Rye Grass has definitely increased the wool production per head over well-fertilised natural pasture, although the increased wool produced of recent years from the natural pasture indicates that the continued applications of fertiliser are gradually bringing these pastures nearer the production ability of the sown pasture.

Results, however, continue to show little difference from the various types of fertilisers used on the sown pasture. Those ewes grazing on the pasture fertilised with Rock Phosphate have yielded 9lbs. 3ozs. wool each per annum, those on pasture fertilised with Superphosphate have yielded 9lbs., whilst those on that fertilised with Lime or Gypsum and Superphosphate have yielded 8lbs. 13ozs.—a difference of only 6ozs. per head between the highest and lowest averages.

HEALTH OF SHEEP.

With reference to the health of sheep in these flocks, the following table shows the deaths and percentages that have occurred during the five seasons under review:—

TABLE 19.—*Deaths of Comeback Ewes*, 1930-35.

Total KI	0 (0%)	0 (0%)	1 (4·17%)	1 (3·23%)	1 (1·96%)	1·87%

The losses in 1934 were approximately equal on both types of pasture, there being four deaths (2.08 per cent.) on sown pasture amongst 192 ewes, and one death (1.96 per cent.) on natural pasture amongst 51 ewes. It is noted that most deaths occurred during 1931 amongst the flocks grazing on sown pasture. The loss was 7.78 per cent. that season—more than double the loss of any other year—and these deaths were due almost entirely to Entero-Toxaemia, which affected the sheep during late winter and early spring.

For the five seasons the average loss on the sown pasture has been 3.85 per cent. per year, and on the topdressed natural pasture 1.87 per cent., showing that where the system of rotational grazing has been observed throughout the growing periods, the losses have not been unduly high, but have been somewhat higher on sown pasture than on natural pasture. This fact is verified by referring to an earlier portion of this paper, in which it is shown that the losses amongst 87 ewes in Flocks A, B, C, and D on natural pasture have only been 1.53 per cent. per annum over a period of six seasons. The deaths on natural pasture have occurred more amongst six and eight-tooth ewes, whereas the deaths on sown pasture have been greatest amongst younger ewes. The losses have been slightly greater on sown pasture when fertilised with Lime and Superphosphate, than when fertilised with Rock Phosphate, 4.8 per cent. and 4.05 per cent. respectively, whilst they have been 2.9 per cent. on clover fertilised only with Superphosphate. The greatest loss has occurred amongst ewes born in 1930 and reared on sown pasture, their annual loss being 4.49 per cent. These ewes lost heavily as two and four-tooths, but this year no deaths occurred amongst them.

The losses of lambs on the two types of pasture have been, between birth and marking, 5.6 per cent. on natural pasture and 18.1 per cent. on sown pasture, and between marking and weaning, 11.5 per cent. on natural pasture and 3.2 per cent. on sown pasture.

Finally, in this experiment, by allowing for deaths, and discounting lamb grazings, and counting the actual ewes carried on these plots, we find that the following wool per acre per annum has been produced by the various aged ewes:—

During five seasons the 1929 ewes have yielded 32lbs. 6ozs. on sown pasture, and 23lbs. 9ozs. on natural pasture—37 per cent. increase.

During four seasons the 1930 ewes have yielded 34lbs. 5ozs. on sown pasture, and 22lbs. 7ozs. on natural pasture—53 per cent. increase.

During three seasons the 1931 ewes have yielded 31lbs. 13ozs. on sown pasture, and 26lbs. 6ozs. on natural pasture—21 per cent. increase.

During two seasons the 1932 ewes have yielded 33lbs. 11ozs. on sown pasture, and 26lbs. 6ozs. on natural pasture—28 per cent. increase.

For one season the 1933 ewes have yielded 34lbs. 10ozs. on sown pasture, and 30lbs. 12ozs. on natural pasture—13 per cent. increase.

These figures show a consistent difference, and an increased production of 30 per cent. in wool per acre due to the cultivated pasture.

PHALARIS TUBEROSA COMPARED WITH WIMMERA RYE GRASS.

Five seasons' results are now available of two five-acre plots, comparing *Phalaris tuberosa* with Wimmera Rye Grass, and an additional three plots of each were established in 1934 for a further five-year test of the two grasses for developing sheep and wool production. They are all grown in combination with Subterranean Clover, and in 1934 the two older established plots were both grazed until towards the end of September, then closed from stock, and mown in November for hay.

Table 20 shows the grazing yields for the five seasons, and the yield of cured hay per acre taken from the plots.

TABLE 20.—*Sown Grasses and Subterranean Clover*, 1930-35.

Season.	Grazing (Sheep per Acre).	
	Wimmera Rye and Subterranean Clover.	*Phalaris tuberosa and* Subterranean Clover.
1930-31	2·47	1·64
1931-32	1·70	3·52
1932-33	2·41	3·82
1933-34	3·70	3·52
1934-35	2·93	2·58
Mean grazing	2·64	3·02
Hay yield, 1934-35	1 ton 1cwt. 45lbs.	1 ton 1cwt. 67lbs.

These results show that for the five seasons *Phalaris tuberosa* and Subterranean Clover have carried 3.02 sheep per acre, 0.38 sheep more than the Wimmera Rye and Subterranean Clover, although for the immediate past two seasons the latter has produced more feed than the *Phalaris tuberosa.*

The three pairs of plots established in 1934 were all sown with 4lbs. of grass seed per acre. One pair was sown on land that had been under topdressed Subterranean Clover for 10 years, and produced very fine stands of both grasses. Grazing was taken from them during late winter and early spring, and they were closed from stock in mid-September, and cut for meadow hay on 19th November. The Wimmera Rye Grass plot yielded 1.63 sheep per acre in grazing, and 2 tons 1cwt. 99lbs. baled hay per acre. The *Phalaris tuberosa* plot yielded 0.59 sheep per acre in grazing, and 1 ton 9cwts. 26lbs. baled hay.

Another pair of plots was sown on land that had been under topdressed clover for four years, and produced good stands of both grasses, but not nearly such thick and vigorous growths as the former two plots that had been under clover for the longer period. The Wimmera Rye plot was grazed until 26th September, and then allowed to mature, and produce ample seed. A fair amount of summer grazing was obtained, and for the season 1.88 sheep per acre were carried. The *Phalaris tuberosa* was grazed until October, and mown for hay in November. This plot yielded 19cwts. 98lbs. cured hay per acre, and 1.45 sheep in grazing, but approximately half of the grazing was secured from the aftermath during the summer months. Both of the above pairs of plots received 1cwt. 45 per cent. Superphosphate per acre at seeding.

The third pair of plots was established on virgin land that was fallowed in December, 1933, and sown down in May, 1934, with 4lbs. grass and 4lbs. Subterranean Clover seed, and 2cwts. 45 per cent. Superphosphate per acre. The growth of grass on these plots was very much less, but quite useful stands were obtained. The Wimmera Rye yielded 0.96 sheep and the *Phalaris tuberosa* 0.87 sheep per acre, but the former could not be fully grazed in spring, as it was necessary to allow it to seed well.

These results are typical of the two grasses, the Wimmera Rye is invariably the better producer during the first season of growth, and very little feed is available from *Phalaris tuberosa* during its first winter after autumn sowing. Moreover, on these types of soils, the advantage of soil preparation with some years' clover growing before seeding an expensive grass like *Phalaris tuberosa* is considerable. Wimmera Rye is the better grass to use initially with Subterranean Clover for the development of these lands.

HAWKE'S BAY PERENNIAL RYE GRASS.

Hawke's Bay Certified Rye Grass has been sown in four two-acre fields—No. 9D was sown in 1931, Nos. 9C and 9B in 1932, and No. 9A in 1934, the former with Alsike Clover, and the latter three in combination with Subterranean Clover. Some *Phalaris tuberosa* was included with the 1932 and 1934 seedings, but this made very little growth during the first season, against the early vigorous growth of Rye plants. Consequently the bulk of the grass growth produced has been Rye Grass, and it has proved inadvisable to sow *Phalaris tuberosa* in conjunction with Perennial Rye Grass.

The grazings received from the four fields since seeding to pasture have been as follows:—

TABLE 21.—*Hawke's Bay Rye Grass Grazing Results, Kybybbolite,* 1931-35.

Field.	Season.	Grazing (Sheep per Acre.)

No. 9A	1934-35	5·00
Mean	....	2·97

The comparative high first-year yields of Fields Nos. 9B and 9A are due to the pastures being sown on well-prepared fallowed land, the other two were sown on cereal stubbles. The average of 2.97 sheep per acre per annum is a good return from the grass, which gives a very useful bite of green quickly following summer and autumn rains, but does not provide as good winter growths as the annual grasses. It is noticeable that the plants appear to be persisting a little better than those in previous trials, but nevertheless the percentage of Rye Grass in these pastures has been diminishing each season, and the amount of annuals increasing. There has been a very heavy death of Rye Plants this last summer, the third and fourth summer after establishment.

Careful readings of counts and estimations of plant species are being recorded, and the following table shows the average monthly percentage estimations of pasture species for two seasons in the three fields established in 1931 and 1932:—

TABLE 22.—*Botanical Analysis of Perennial Rye Grass Fields.*

Species.	Field No. 9D.		Field No. 9C.		Field No. 9B.	
	1933.	1934.	1933.	1934.	1933.	1934.
	%	%	%	%	%	%
Perennial Rye Grass	53·8	41·4	50·0	35·5	32·7	22·6
Annual Grasses	—	14·2	—	17·8	—	2·5
Phalaris tuberosa	—	—	0·8	1·6	6·7	8·3
Clovers	8·5	18·2	22·5	30·1	31·8	54·8
Erodium	—	0·3	—	trace	—	trace
Capeweed	—	trace	—	0·1	—	0·2
Miscellaneous	6·4	6·7	12·0	3·5	12·5	2·8
Bare Space	31·3	19·2	14·7	11·3	16·3	8·8

The principal factors revealed by this table are (1) the reduction by 27 per cent. in 1934 of the amount of Perennial Rye Grass on the three fields, (2) the increase by 32 per cent. in the amount of *Phalaris tuberosa* on the two fields in which it was sown, (3) the increase by 64 per cent. in the amount of Clover growths in the three fields, (4) the influx of annual grasses on all fields, especially Nos. 9D and 9C (5) the reduction of amount of bare space by 37 per cent.

The following table of counts of plants taken from five fields containing Perennial Rye Grass, and four fields containing *Phalaris tuberosa*, during the last three autumns, further illustrates the poor persistency of Perennial Rye Grass against the good persistency of *Phalaris tuberosa*.

TABLE 23.—*Counts of Perennial Grass Plants, Kybybolite,* 1933-35.

	Plants per Square Metre.		
	1933.	1934.	1935.
Hawke's Bay Perennial Rye—			
Field No. 9D, sown 1931	87	64	23
Field No. 9C, sown 1932	63	54	6
Field No. 9B, sown 1932	100	50	3
Field No. N1, sown 1932	111	101	4
Field No. N2, sown 1932	79	86	5
Means	88	71	8
Phalaris tuberosa—			
Field No. 9C, sown 1932	11	14	10
Field No. 9B, sown 1932	37	29	32
Field No. N1, sown 1932	6	6	5
Field No. N2, sown 1932	5	9	6
Means	15	14	13

This result shows the death of Perennial Rye Grass plants during 1933-34 to have been 19 per cent., and in 1934-35 to have been 72 per cent. The death of these during last summer was extremely high, in only one field (No. 9D) have they persisted much at all, but the plants in this field are not very healthy. This latter field is one, without Subterranean Clover, hence it is apparent that the heavy growth of clover in the other fields so used the available moisture last season that there was insufficient soil moisture left to keep the Rye Grass plants alive.

The deeper rooted *Phalaris tuberosa*, however, did not suffer in this respect, and in every field the plants are persisting.

Field No. 9B, sown in 1932, was divided at seeding into five equal sections, and sown with various mixtures of Perennial Rye Grass and *Phalaris tuberosa*, all with 2½lbs. Subterranean Clover seed and 1cwt. 45 per cent. superphosphate per acre. The following table shows the percentage monthly estimates of pasture species growing on them during the last two seasons.

TABLE 24.—*Botanical Analysis of Pasture Mixture Plots,* 1933-35.

Species.	Plot No. 1, *Phalaris* only.		Plot No. 2, Per. Rye only.		Plot No. 3, *Phalaris* 50%, Per. Rye 50%.		Plot No. 4, *Phalaris* 66%, Per. Rye 33%.		Plot No. 5, *Phalaris* 33%, Per. Rye 66%.	
	1933.	1934.	1933.	1934.	1933.	1934.	1933.	1934.	1933.	1934.

Capeweed	—	trace	—	0·1	—	—	—	0·1	—	1·0
Erodium	—	0·1	—	—	—	—	—	—	—	—
Miscellaneous	27·9	8·6	8·7	1·1	9·1	0·6	7·7	1·7	8·9	2·1
Bare space	19·2	8·0	14·4	8·3	14·9	8·6	14·7	7·9	18·5	11·0

Factors to be noted from this table are (1) the reduction of Perennial Rye Grass on every plot, an average of 31 per cent. on its four plots; (2) increase of *Phalaris tuberosa* on every plot, an average of 24 per cent. on its four plots; (3) the small amount of *Phalaris tuberosa* on plots where it was sown in conjunction with Perennial Rye Grass, whereas on Plot No. 1, where it was sown alone, there has been in 1934 a greater percentage of grass than any of the other four plots; (4) a little annual grass has come on four of the plots during 1934; (5) increase of Subterranean Clover on all five plots, averaging 75 per cent. more in 1934.

Finally, the results from this work with Certified Perennial Rye Grass shows that it is not suitable for permanent pasture under local conditions. Few plants persist more than three seasons, and unless a strain can be evolved particularly suitable for the conditions it will not be advisable to continue with its culture.

Phalaris tuberosa on the other hand is persisting well, and is the only perennial grass that so far has proved itself suitable for sown permanent pastures under these conditions of soil and climate.

SUBTERRANEAN CLOVER.

The grazing results of general fields of the Farm, outside the purely experimental areas have been recorded. Those established with Subterranean Clover have been grouped together, and Table 25 shows the results for the past 11 seasons:—

TABLE 25.—*Subterranean Clover Grazing, Kybybolite,* 1924-35.

Season.	No. of Fields.	Area.	Total Feed Days.	Sheep per Acre.
		Acres.		
1924–25........................	1	29·50	29,469	2·74
1925–26........................	3	109·00	100,794	2·53
1926–27........................	5	181·50	141,041	2·13

1933–34........................	8	205·62	210,492	2·80
1934–35........................	12	288·58	321,279	3·05
Total		2,151·73	2,024,710	2·58

Fields from which meadow ensilage and hay have been cut have not been included in the above table, and the results do not represent the full grazing capacity, as it has not been practical to graze all fields completely. The return this season of 3.05 sheep per acre is the best so far recorded, an increase of ¼ sheep on the previous season. The average for 11 seasons of clover grazing shows at 2.58 sheep per acre per annum. The fields have not been top dressed regularly of recent years, but have averaged approximately 85lbs. superphosphate per acre per annum.

TOPDRESSING OLD CULTIVATED LAND.

Certain fields have been used for crop cultivation periodically, and left out for grazing during intervening seasons. Those top dressed with superphosphate, but not sown with grasses or clovers, have been grouped together, and their grazing returns for the past 10 years are given in Table 26:—

TABLE 26.—*Grazing of Top Dressed Cultivated Land, Kybybolite,* 1925-35.

Season.	No. of Fields.	Area.	Total Feed Days.	Sheep per Acre.
		Acres.		
1925-26	1	50·00	30,097	1·65

1934-35	2	36·47	27,061	2·03
Total		1,075·66	883,984	2·25

Similar land left out of cultivation but not top dressed has, during the past seven seasons, carried 1.35 sheep per acre, nearly 1 sheep per acre less than that which has been top dressed.

As a comparison to the above table the following two tables are included to show the grazing received from similar land that has never been cultivated. Table 27 shows the combined results of all such land that has been top dressed, whilst Table 28 shows the results from unimproved natural land, that is, land that has neither been cultivated nor top dressed:—

Total		755·54	193,235	0·70

The results from Tables 25 to 28 show what a large improvement in grazing capacity can be obtained on these lands. Just by ordinary general methods, land of a carrying capacity of 0.70 (Table 28) sheep per acre has been increased 370 per cent. to 2.58 sheep under Subterranean Clover (Table 25). From the results of experiments, given in earlier part of this report, where the grazing has been more complete and controlled 3.45 (Table 8) sheep per acre have been carried over a 10-year period on similar soil conditions, growing Subterranean Clover and Wimmera Rye Grass. This latter shows approximately 500 per cent. improvement.

TRIALS OF GRASS AND HERBAGE STRAINS.

The work of strain testing, assisted by the grant made by the Australian Dairy Council, and commenced in 1932 is proceeding steadily.

Some definite result in improvement in strains of Wimmera Rye Grass is well in hand; several good productive ones have been isolated, and will this season be planted out under field conditions, whilst the work of further selection and test will be maintained on small plots.

Also two strains of *Phalaris tuberosa* have been isolated, and it is also anticipated to be able to transplant a line of typically good persistent plants of Perennial Rye Grass this year from the 200 noted individual plants that have been growing under field conditions during the past three seasons.

In conclusion I wish to record the valuable assistance given by the staff of the Farm throughout the season, and especially the work of Farm Assistant Mr. J. D. McAuliffe, who has assisted materially with pasture estimations, checking, and preparation of this report.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1934-35.

[By A. R. CALLAGHAN, D.Phil., B.Sc. (Oxon.), B.Sc.Agr. (Syd.), (Principal), E. J. BREAKWELL, B.Sc.Agr. (Syd.), (Plant Breeder), and S. R. KLOSE, R.D.A., (Field Officer).]

PART IV.—CEREAL BREEDING, EXPERIMENTS AND PURE SEED PRODUCTION.

For many years now the College has been engaged in wheat breeding and experimental work with cereals. Those conversant with the agriculture of the State realise the importance of the work already performed in this field. At the present time a College bred variety, Sword, is forging its way into popularity; in 1932 this variety was not even in the first twelve of the most important varieties grown in point of acreage, in 1933 it was eighth on the list and in 1934, fourth. Then again Ford, another College bred wheat, is gaining in favour, because of its baking quality; this variety is achieving greatness in New South Wales where its all round value has been appreciated by the farmer to the extent of making it the second most popular variety grown in that State. Ford is now fourth on the list of the leading varieties grown in Australia.

Apart from the breeding of new varieties, pure seed production plays a very important part in the efficiency of wheat growing in any State and it is an aspect that cannot be neglected. The work involved in keeping varieties true to type and propagating the right strains of pure seed can only be done systematically at an institution such as the College. Superimposed on the plant breeding and pure seed production functions of the College is the experimental work connected with all phases of the agriculture carried out on the farm. At such a centre, where practical leadership in agriculture is expected, experiments must of necessity be conceded a very important place in the field work, for without experimenting, thought and ideas never mature beyond the boring stage of hypothesis.

All these phases of development and investigation undertaken by the College vitally affect the wheat industry of the State, and whatever may be imagined to the contrary, it is safe to maintain that they could not be neglected without seriously jeopardising the prestige and efficiency of the South Australian farmer. The work in question demands great care, attention to detail, extensive record keeping and a superabundance of labour. Fortunately students supply the labour required and if this were not so the cost of such work would be very materially increased. On the present basis, students benefit considerably by constant and detailed contact with the work and in return their labour makes it possible. The same amount of hand seeding, "rogueing" and hand harvesting carried out with labour at basic wage rates would increase enormously the costs to the State. While the students enjoy the educational advantages the system offers and gladly respond with their labour, it is possible to keep such costs at a minimum. Not the least pleasing feature of this symbiotic relationship is that full confidence and trust in the students to do the work conscientiously, with full regard to its importance, is met by them with a response that assures extreme care and efficiency.

It is proposed in this part of the report to outline the cereal work that is being attempted along the lines indicated above. Detailed results will be made available as experimental results become more conclusive; this resumé of the work is merely an attempt to keep the primary producer and others concerned interested in important developments which take place from year to year.

CEREAL BREEDING.

In the past few years the whole of the wheat, oats and barley breeding work has received careful and thorough revision. Detailed accounts covering the objectives, the manner and means of attainment, and the nature of the revision deemed necessary to bring all procedure into line with modern knowledge and requirements, have been published in previous issues of the *Journel* (July, 1933, and August, 1934). Moreover in a previous section of this report (Part III.) the methods adopted for breeding for improved baking quality in wheat have been outlined and the extent of this phase of the work being conducted at the College has been described at length. In this connection although breeding for baking quality necessitates the use of slightly different methods to those commonly employed for the breeding for other desirable characters, the same fundaments apply.

A full account of the conditions prevailing throughout the season has been given in Part II. of this report. The specialised work under review was probably more deeply affected by the lack of rain at the beginning of the season than is reflected by the farm yields. The plant breeding plots never fully recovered from the malting of a considerable amount of grain, and the ravages of birds, especially innocent and unsuspected magpies. In addition, the relatively vigorous early growth of weeds had a deleterious effect upon yields in the plots. However, the progress of the work was in no way delayed and in some respects the season was a particularly valuable one.

The dry opening enabled valuable observations to be made on drought resistance in the cross-bred material, and it is significant to note that distinct variation was obvious even in the early stages of growth. It is very probable that resistance to dry conditions between seeding and flowering is equally important as resistance to dry conditions after flowering, the latter resistance, in fact, is very largely dependent upon the resistance to drought in the early stages. This supposition is based upon observation, for it was noticed that certain crossbreds, particularly those from the parent Egyptian 4, which were healthy and vigorous throughout the dry winter, maintained their superiority over those which staged a remarkable recovery after the August rains, following a comparatively dormant and unhealthy beginning.

OBJECTIVES OF WHEAT BREEDING IN RELATION TO BREEDING FOR QUALITY.

Comparative early maturity, drought resistance and general capacity for thrifty growth, coupled with good finishing characteristics remain the outstanding objectives of the wheat breeding programme, notwithstanding the fact that disease resistance and baking quality have also entered very largely into all the work. The latter two aspects have of late years become more important and consequently have been showered with publicity, especially breeding for better quality. If in the enthusiasm of outlining the work on quality, because of its immediate importance, there has been an overshadowing of the basic objectives, some correction is necessary. These remarks and those to follow on disease resistance are meant to allay any suspicion which may have arisen that the College was paying attention to the breeding of better quality wheats to the detriment of other objectives such as suitability to the environment, drought resistance, general early maturity, qualifying characteristics of agronomic value, and disease resistance. Probably there are more crossbred lines, incorporating these objectives, being tested annually than ever before in the College history, the quality programme is superimposed on this foundational work so that in point of fact nothing is being sacrificed in any way.

DISEASES.

In this year's report some more detailed information with respect to breeding for disease resistance is warranted, and each disease will be treated separately.

Flagsmut.—**During the season under review flagsmut was very prevalent in the breeding rows.** Where susceptible strains were inoculated with spores of the disease (*Urocystis tritici*), excellent infection was obtained, frequently as high as 100 per cent. Such heavy infection in susceptible lines increases the significance of non-infection in other lines, thereby strengthening their claim to complete resistance. Two years observations have shown that among advanced crossbred lines there are some which possess either immunity or a very high order of resistance to flagsmut; these, and many hundreds of lines in the third generation are being tested, per medium of inoculation, for flagsmut resistance, during the present season.

There are several quite good varieties of agronomic value which possess resistance to flagsmut. This fact simplifies the work and the task is not an insuperable one provided a judicious choice of parents is made. There can be no doubt that resistance to flagsmut is a quality to be desired; in fact the rapid widespread use of Nabawa throughout Australia was brought about chiefly because of its great character of resistance to this disease.

Stem Rust.—Towards the close of last season, stem rust (*Puccinia graminis tritici*) was so severe in the hand plots that selection for resistance to this disease was possible. Segregation for resistance was very marked in crosses containing the high quality and disease resistant variety Hope and to a lesser extent in all Ford crosses.

Although the average farmer is fully cognisant of the damage caused by stem rust, the disease receives publicity only once in every several years, since epidemics are relatively rare in this State. When they do occur, however, the effect is rather disastrous.

Breeding for rust resistance presents more difficulties to the plant breeder than does breeding for flagsmut resistance. Firstly, varieties possessing a combination of rust resistance and high yielding ability are rare. Ford is a notable example but even this variety shows an abundance of rust lesions on the stem though the grain sample is not seriously affected. The difficulty in selecting plants from Ford crosses in the field is obvious; the epidemic must be severe, and the grain of the plant must be examined before the plant breeder can determine whether it possesses true resistance..

There are a number of varieties which are immune or very highly resistant to stem rust. Unfortunately these are nearly all unsuitable for Australian conditions and moreover, they have red grain In any population parented by a red and a white grained wheat, the vast majority of the plants possesses red grain and selecting the white grained segregates from such populations is very laborious. This has been done, however, in a number of crosses made between red grained, rust resistant varieties and commercial white grained Australian varieties, in an endeavour to evolve a rust resistant, white grained type, which will be valuable for crossbreeding purposes, if not commercially.

The second difficulty encountered in a rust breeding programme is that an epidemic is required every year to render possible the selection of rust resistant plants. During the current season artificial means of inducing rust will be resorted to in an endeavour to save time and prevent the continuance of lines which may ultimately succumb to the ravages of the disease. The bird proof enclosure is being used for this purpose. A few grains of most lines, which on the basis of their parentage, might be resistant to stem rust, are sown within this enclosure, rows of a susceptible variety being sown at intervals amongst the lines. Soon after flowering the susceptible variety, which is seeded earlier than the crossbred lines, is inoculated with the disease. This is done by injecting a suspension of rust spores into the stems by means of a hypodermic needle. The northern and western sides of the enclosure are protected from the hot dry winds and by using a sprinkler during the late spring, suitable conditions of humidity will be created and the rust on the susceptible variety should soon attack the susceptible crossbred lines. In the hand plots, selection will be restricted to those lines which showed some resistance to stem rust under the artificial conditions. It is obvious that such an arrangement will greatly enhance the prospects of breeding rust-resistant varieties.

Leaf Rust.—Leaf rust or spring rust (*Puccinia triticina*) is nearly always present under College conditions but it cannot be considered a serious disease. Observations are made, however, on its occurrence in crossbred material. Although seldom serious, epidemics are common, which makes easier the task of selecting resistant types, but as with the stem rust work, the main difficulty is that breeding material possessing the combination of resistance and yielding ability, is rare.

Bunt.—Owing to the dry conditions of seeding, bunt (*Tilletia tritici*) was also prevalent in the hand plots. Lines of all crosses which contain a bunt resistant parent are inoculated with bunt spores before seeding and observations made on the susceptibility of each line. While resistance to bunt is considered desirable and the plant breeder looks to it as an objective, it is not absolutely essential, for the pickling of seed wheat is now almost universally practised throughout the State and is quite effective in checking the disease.

Loose Smut.—The control of loose smut (*Ustilago tritici*) is more difficult and resistant varieties are greatly to be desired. Unfortunately, however, there are only a very limited number of varieties which are resistant to this disease and none possesses desirable agronomic characters, hence their value for cross breeding work is problematical. Moreover, testing for loose smut resistance entails a great deal of time and labour. In view of these considerations the more important objectives receive priority and at present it is not proposed to embark on a definite loose-smut breeding programme. Efforts to combat the disease will be confined to the raising of pure seed free from loose smut and observations on resistance of crossbred lines whenever the disease makes its somewhat sporadic appearance.

Take-All.—Although a very important disease, Take-All (*Ophiobolus graminis*) has received little attention from the wheat breeder. The reason for this is that to date, no variety has been discovered which is resistant to the disease. For some years at least, therefore, the wheat farmer must not look to the plant-breeder for relief, but must rely upon recommended cultural methods to combat the ravages of "Take-All".

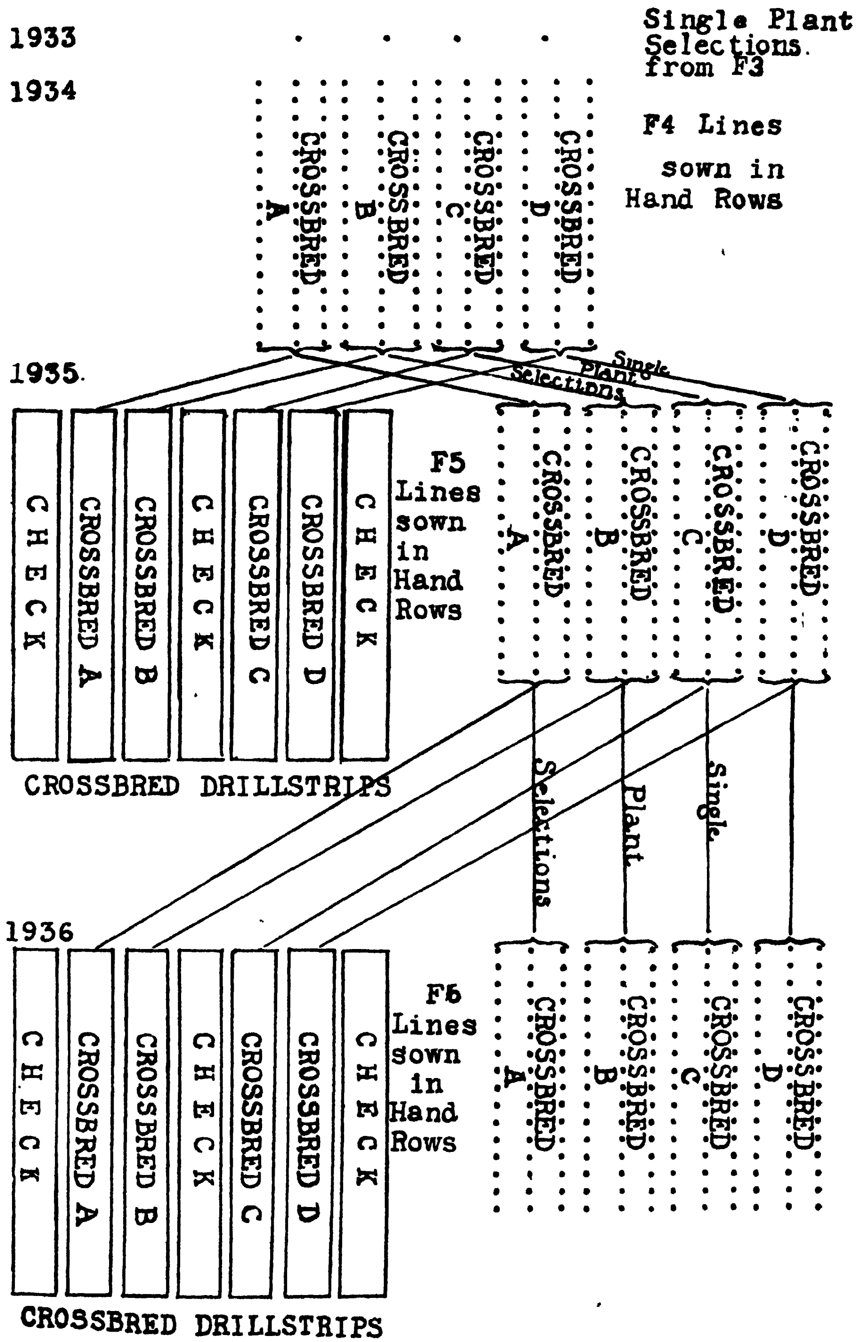
Septoria.—The damage caused by the Septoria leaf spot (*Septoria tritici*) has never been determined but it is unlikely that it will assume proportions sufficiently serious to warrant the intensive attention of the wheat breeder.

CROSSBRED DRILL STRIPS.

A recent innovation in the plant breeding work, which was tested for the first time in the 1934 season, was the growing of crossbred drill strips. Promising lines in advanced generations from the hand plots were sown through the drill in strips four hoes wide and one chain long. Every third strip was sown with a standard variety of repute for comparative purposes. This system serves as a preliminary yield trial for crossbred material; moreover the field behaviour of the different lines can be observed—an important consideration since this is quite often different from plot behaviour. Single plant selections of each line growing in the drill strips are sown in rows in the hand plots and further selection is restricted to these rows, the bulk seed from the rows will in turn sow the drill strips the following season.

The system of sowing drill strips should have the effect of speeding up the breeding programmes in so far that the fixation of the lines proceeds as usual but, in addition, by the time they are fixed, a reasonably accurate impression of their field behaviour will have been obtained, permitting a reduction in the time taken for normal field tests of fixed crossbreds. Moreover it will be possible to conduct baking tests in relatively early generations.

System of Testing Crossbred Lines.



Diagrammatic Representation of System of Testing in Crossbred Drillstrips.

It is proposed, in the future, to carry out a certain amount of extension work from the College in connection with wheat breeding, and in this scheme drill strips of the type described above will be sown on farmers' properties in different centres of the State. The adaptability of promising crossbred lines to the various environmental conditions of the State will thus be determined in the early stages of the work, thereby greatly facilitating the selection of lines suitable to the different districts.

INTRODUCTIONS.

A number of varieties were introduced from sources outside the State during the year and some of these, on one year's performance have shown promise both directly for their yielding ability and indirectly for their potentialities as parents for crossbreeding purposes. Recent introductions from Canada possess not only immunity to stem rust but also to flagsmut and leaf rust. Moreover they are much better agronomic types than other disease resistant varieties available in the past, although they have red grain. Three varieties from Kenya Colony which are white grained and have very fair agronomic characters show a high order of resistance to stem rust and flagsmut; these should be particularly valuable in the crossbreeding work. Other introductions looked promising on one year's performance but it would be premature to attempt to forecast their future utility.

OAT BREEDING AND INVESTIGATIONS.

In the past, farmers of South Australia have had to rely mainly on oaten varieties introduced from New South Wales, where conditions and soils are vastly different from those in this State.

A definite oat breding programme has therefore been embarked upon in an endeavour to evolve an oat which will be particularly suited for our Mallee soils. The primary objectives are early maturity and yielding potentiality combined with the power of recovering after grazing.

At present, systematic hay, grain and grazing trials are being conducted at the College and some valuable data concerning the relative merits and demerits of the various varieties have been collected therefrom. Selections have been made from some of the more common varieties such as New Zealand Cape, Early Kherson, Algerian and Sunrise and some of these look very promising. They will be subjected to yield trials during the next season.

BARLEY BREEDING.

The cultivation of barley for malting purposes is not likely to expand to any extent in the near future and it is sufficient to meet the dictates of the moment. Breeding for improved malting quality is difficult, for the plant breeder has no medium for the selection of this character except that of the eye. Early maturity is an essential in a malting barley suitable for South Australian conditions and it is highly probable that late maturity and high malting quality are linked—more in a physical than in a genetical sense. Efforts are being made, however, to combine the high malting quality of varieties such as Spratt Archer, Plumage Archer and Beavan's Special with the more prolific and earlier maturing Prior; lines of such crosses are now in advanced generations.

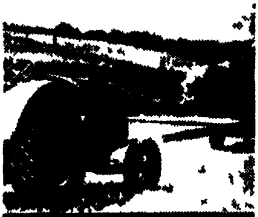
In the six-row types, prolificacy is the main essential but crosses have also been made between these types and Prior in an endeavour to produce a six-row barley with fair malting quality for overseas requirements.

Varietal investigations with barley are being conducted and some promising six-row types are now being tested in the field trials.

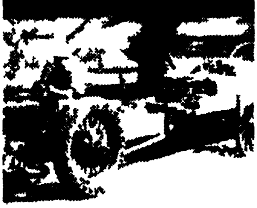
PURE SEED PRODUCTION.

The method used at the College in the propagation of pure seed of existent varieties, based on the foundation of single plant selection and multiplication therefrom, was outlined in an article published in the *Journal* for July, 1933.

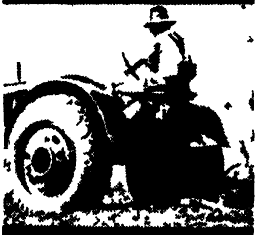
HARVESTING



BELT WORK



HAULING



CULTIVATION

ALL THE YEAR-
ALL THE JOBS!

Whether it's ploughing, cultivating, sowing, harvesting, belt work, or the odd hauling jobs of winter, Goodyear All-Weather Farm Implement Tyres make it possible for your tractor to cover more acres, do more work —faster, better, more economically.

Fitted with Goodyear Farm Implement Tyres your tractors know no seasons.

Farmers all over Australia report that Goodyear Farm Implement Tyres on their tractors have resulted in greater speed—more high-gear work—longer tractor life because of smoother going—roadway hauling without wheel changes—better grip in any kind of soil whether going forward, backward, or on hillsides—resulting in a substantial saving in fuel, oil, labor and time.

Goodyear Farm Implement Tyres and Wheels are now available on Hire Purchase Terms. For full particulars write to the Goodyear Branch (in all capital cities).

This scheme is now in full operation. Sales of pure seed have increased considerably over the past two years clearly illustrating that the farmer is appreciative of seed true to type, free from loose smut and barley. Last year there was a particularly heavy demand for Sword, Ford, Ranee 4H and Dundee. The varieties Early Gluyas and King's White were popular and there were limited demands for Waratah, Sultan, Baringa, Nawab, Nabawa, and Huguenot.

The demand was greater than the supply, especially in some varieties, but by insisting on farmers only being allotted small lots of a few bags each, a wide and equal distribution of good seed was possible. Actually the College is not anxious to fill big orders of one variety for any one client, as the main object is to supply the grower with pure seed which he can multiply and use for his own requirements, while ever it remains free from admixture and is otherwise satisfactory. When he considers it necessary to renew his line a fresh start should be made from the pure seed lines at College; these lines are actually maintained for the farmer and it is hoped that at all times full advantage of the work will be taken.

From the varieties Sword and Ford, which have shown considerable variation, a number of strains have been fixed. These are now being tested for yield but will not be available for distribution for some time yet. For the present, a relatively pure commercial strain of Sword being grown at the College is giving good results; this strain is practically free from the "brown-head" and the purple straw type commonly found in Sword. Likewise, a reliable and typical strain of Ford, which should satisfy requirements for the next two or three years, is available to farmers.

A large seeding has been made this year of varieties of oats, for indications suggest that the demand will be heavy. For the 1935 seeding, farmers made numerous inquiries for an early grazing oat which would recover quickly to give a satisfactory harvest of hay and grain. For the present Early Kherson is to be recommended in this respect and ample provision for seed of this variety has been made.

The College will be in a better position to advise on the suitability of particular oaten varieties when more detailed field trials have been conducted. Meanwhile, New Zealand Cape and Algerian are recommended for early and Early Kherson for later sowing.

CEREAL VARIETY TRIALS.

Method.—All variety trials are conducted on a replicated system of randomised plots. The idea is to satisfy practical as well as scientific requirements.

For *practical* purposes the plots are about 5ft. 9in. wide, or 9 drill hoe widths, and are 3.19 chains in length. Each plot is thus 1/40th of an acre and can be handled quite conveniently with the use of an ordinary drill and stripper.

Replications are necessary to make sure that the differences being measured are differences between the varieties and not differences due to other factors such as soil variation. This also enables a *scientific* interpretation of the results to be made, enabling the actual significance of the results to be assessed.*

The standard error (S.E.) aimed at in trials of this nature is 2 per cent. Those obtained from last season's experiments were all larger than this, but with the exception of the Mid-season Wheat yield trial, which was badly checked by weeds, all experiments must be considered as very satisfactory, since the S.E. is lower than 3 per cent. In a normal year a 2 per cent. error should be attained without much difficulty.

---

*Fisher's Analysis of Variance was applied to all the results obtained from the replicated trials. All experiments in 1934 were found to be very significant (P = 1 per cent) by the Z method.

In the discussion of results, only the S.E. and the significant differences will be shown. In interpreting the results, only those differences which are equal to or greater than the significant difference quoted for the experiment should be given credence. In other words the margin of error signifying a real difference due to the variety itself is stated by the significant difference.

Late Wheat Variety Trial.—The results of this trial are set out in the accompanying table. The conclusions that can be inferred from these results are that Ford Selection and Baringa are approximately equal and both, for the season of the trial, were significantly superior to the rest of the varieties tested. On the other hand there was no difference between Free Gallipoli and Ford, as the difference recorded is not a significant one; in other words under identical conditions it is probable that the two varieties would give practically equal results. Dundee in these results has given a significantly superior yield to both Free Gallipoli and Ford.

ROSEWORTHY AGRICULTURAL COLLEGE.

RESULTS OF WHEAT VARIETY TRIALS, 1934.

Late Maturing Varieties.

Variety.	Yield per Acre. bush.	Yield per Acre. lbs.	Percentage Yield.
Ford Selection	**30**	**28**	**116**
Baringa	**30**	**12**	**115**
Dundee	**28**	**44**	**109**
Free Gallipoli	27	16	104
Ford (standard)	26	20	100

S.E. = 2.6 %. Significant Difference = 88lbs. per acre.
Significant results in comparison with the standard *Ford* are in block type.

Ford Selection in this trial has again shown its ability to yield well; in addition it is a useful hay variety. On the other hand it is later than Ford and lacks the rust resistance of that variety; it will be necessary, therefore, for it to show substantial superiority in yield over a number of years before it would be wise to recommend it.

Baringa filled its grain exceptionally well and in view of the fact that millers show a slight preference for this variety it is possible that it may have some future in South Australia. One characteristic is that it holds its grain tightly and is sometimes difficult to thresh, but under the average of South Australian conditions this feature of Baringa should not be very serious. It is essentially a grain wheat and will not yield well for hay.

Dundee did not yield up to its appearance but its superiority to Ford last season indicates that it is well worth a trial in South Australia, particularly in the more favoured districts. Its outstanding characters are its good baking quality, strong straw and flagsmut resistance. It is, however, very susceptible to stem rust.

It has been demonstrated once again that *Free Gallipoli* is not a high yielding variety on the drier Mallee soils and in view of its very poor baking quality farmers are strongly urged to test some of the better quality varieties which are available and which are capable of replacing quite adequately the notoriously low quality Free Gallipoli.

Mid-Season Wheat Variety Trial.—In the results tabulated, Nawab is shown to be outstanding and has given a yield placing it above all the other varieties in the trial. The three varieties Sultan, Bobin, and Nabawa in this trial have given equal results as there is no significant difference between them, but all three are inferior to Nawab, and all three have given significantly better results than either Ranee 4H or S.H.J. The variety Minflor has given a significantly inferior yield to all varieties in the trial.

ROSEWORTHY AGRICULTURAL COLLEGE.

RESULTS OF WHEAT VARIETY TRIALS, 1934.

Mid-Season Maturing Varieties.

Variety.	Yield per Acre. bush.	 lbs.	Percentage Yield.
Nawab	**27**	**28**	**122**
Sultan	24	4	108
Bobin	22	28	101
Nabawa (standard)	22	16	100
Ranee 4H	**18**	**56**	**85**
S.H.J.	**18**	**16**	**82**
Minflor	**13**	**0**	**55**

S.E. = 5.3 %. Significant Difference = 136lbs. per acre.

Significant results in comparison with the standard *Nabawa* are in block type.

General View of the Wheat Breeding and Experimental Plots prior to Harvest, 1934.

Nawab was outstanding and over the last six years this variety has outyielded all other varieties grown at the College; its claims, therefore, can no longer be ignored, particularly in the Lower North districts where a dual purpose wheat is desired. Unfortunately it is susceptible to most diseases but its inherent yielding ability compensates in large measure for losses from these causes in most seasons. Its baking quality is quite fair and taking this and its performance in the field into consideration, it can be recommended to farmers for growth on the better Mallee soils, especially where a dual purpose variety is required.

The yield of the newcomer *Bobin* (introduced from N.S.W.) was satisfactory but it has no outstanding characters to warrant its continuance under our conditions.

Ranee 4H in this trial was disappointing. In this group there was strong competition from weeds during the winter months, which appeared to have greater effect on the Ranee than other varieties.

The high quality wheats *S.H.J.* and *Minflor* were failures in comparison with the standard Nabawa, and will be rejected on the score of poor yields.

Early Wheat Variety Trial.—In the trial of early maturing varieties, Merredin and Sword are at the top of the results and both give significantly better yields than any of the other varieties. B.F.G. 3003 is also superior to the standard variety of the trial, Waratah, as is Aussie, but Minflos has given a yield significantly inferior to all varieties.

ROSEWORTHY AGRICULTURAL COLLEGE.

RESULTS OF WHEAT VARIETY TRIALS, 1934.

Early Maturing Varieties.

Variety.	Yield per Acre.		Percentage Yield.
	bush.	lbs.	
Merredin	**21**	**36**	**122**
Sword	**20**	**4**	**114**
B.F.G. 3003	**19**	**4**	**108**
Aussie	**18**	**48**	**106**
Florence	18	4	102
Waratah (standard)	17	40	100
Minflos	**15**	**36**	**88**

S.E. = 2.4 %. Significant Difference = 56lbs. per acre.

Significant results in comparison with the standard *Waratah* are in block type.

Merredin on its first appearance in the field trials at the College, outyielded the reliable *Sword.* It is interesting to note the superiority of Merredin to *Aussie.* The general opinion is that these two varieties are synonymous but slight agronomic differences do exist apart from the difference in yielding potentialities, though the latter may have been affected slightly by the fact that the seed of the two varieties came from widely different sources.

B.F.G. 3003, a promising Queensland introduction, gave a creditable performance and will be tested further.

Waratah was disappointing and in view of its poor baking quality is no longer recommended.

Florence gave fair results and must still be recommended for late seeding particularly as millers are paying a premium for the variety.

Minflos was a failure in the trial.

Yield trials were also conducted with *Gluyas* and *Sword* strains, the results of which are of no interest outside the College. An outcome of the trial with the strains of Gluyas is that the College has adopted the selection Gluyas 32-40, from the Waite Institute, as the standard and pure seed of this strain will be distributed to farmers in the future.

Barley Variety Trials.—Two small yields were conducted with varieties of barley, the results from which are given below:—

ROSEWORTHY AGRICULTURAL COLLEGE.

RESULTS OF BARLEY VARIETY TRIALS, 1934.

(*a*) *Six-Rowed Varieties.*

Variety.	Yield per Acre.		Percentage Yield.
	bush.	lbs.	
Californian Cape (light)	31	34	103
Californian Cape (heavy)	31	18	102
Roseworthy Oregon (standard)	30	44	100
Prior x Roseworthy Oregon	**19**	**26**	**63**

Significant results in comparison with the standard *Roseworthy Oregon* are in block type.

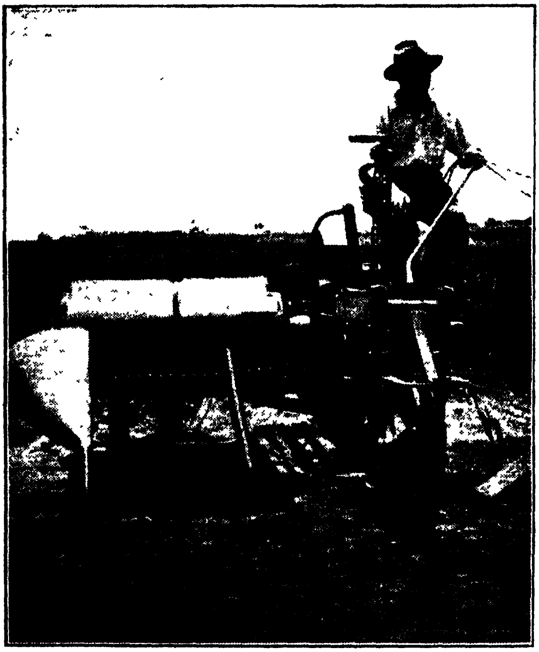
(*b*) *Malting Two-Rowed Varieties.*

Variety.	Yield per Acre.		Percentage Yield.
	bush.	lbs.	
Prior (standard)	40	5	100
Prior x Roseworthy Oregon	39	5	97
Prior Selection	39	5	97

S.E. = 2.45 %. Significant Difference = 74lbs. per acre.

Apart from the fact that it was demonstrated that the crossbred Prior x Roseworthy Oregon is inferior to the standard six-row types, no information of a positive nature was derived from the trials. Californian Heavy and Californian Light, for which there have been some inquiries, possess satisfactory yielding ability and there is some small demand for their grain for the export trade.

Oaten Trials.—Oat varieties for yield testing were sown on fallow and owing to excessive lodging the trial could not be harvested. Early Kherson was the only variety which did not lodge. In the future, oaten trials will either be sown on stubble or on fallow and grazed once. In the current season these trials have been considerably increased and include grazing, hay, and grain groups.



The Third Stage in producing Pure Seed of Wheat and other cereal varieties is the multiplication of seed from the hand plots by growing the produce in long stud rows. This small machine was constructed at the College for harvesting these long rows. It consists of a 3ft. comb, is worked with an auxiliary engine, and drawn by one horse. The machine also does all the stationary threshing of small lots harvested by hand from the breeding plots.

CULTURAL AND MANURIAL EXPERIMENTS.

Working on the basis that example is better than precept, the College experimental work is so designed as to test and demonstrate at the same time the relative worth of different methods or treatments. Actually, to lead the developmental work in all phases of local agriculture is essentially a function of the College, and where developments have taken place or are suggested, it becomes the duty of the College to test their worth.

The nature of the experiments being conducted at any such institution, their scope, aims and general practicability are reflections of the vitality and thought of the institution concerned. At Roseworthy College, the one common feature to all the experimental and investigational work is the emphasis given to the practical and utilitarian aspects. *All experiments are conducted on a practical basis, with practical objectives, yet they are all based on scientific principles to guarantee their accuracy. No manurial or cultivation treatment, weed control or system of fallowing which may be beyond the average farmer as regards means or plant, is either used or advocated.*

Apart from the increased number of variety trials, several new experiments have been initiated within the last two years. Some of these are of the nature of biennial experiments, requiring two years before one result is known. These and others demand repetition before any conclusions are justified, so that at the most, only preliminary reports on the progress being made are available for report herein.

CULTIVATION EXPERIMENTS.

The prevailing low prices for wheat and the growth of mixed farming has brought about a tendency to neglect thorough cultivation of fallows. In some cases the additional returns that might be expected do not offer sufficient incentive to cultivate at every favourable opportunity. Further, with the advent of mixed farming as an almost universal practice, sheep are being used to such purpose in many instances as to take the place of the cultivator. Unwittingly the farmer is probably losing by this partial neglect. With high returns from wool and lambs, enthusiasm for wheat farming as such has waned, and efforts to secure maximum yields from wheat crops are not being made, even though in many cases extra efforts would prove profitable.

In an endeavour to determine the actual value of well prepared fallow in comparison with poorly prepared fallow, a cultivation experiment was commenced at the College in 1933. Incidentally, the experiment was designed so that some measure of the economic worth of each cultivation could be made, and the most important cultivations defined.

The experiments were conducted under field conditions; the plots being marked off in an ordinary fallow paddock. Eight different treatments were allowed for and each treatment was replicated five times. All treatments received the initial and the pre-seeding cultivation, some missed one cultivation at different times of the year, others missed two such cultivations and one series missed three cultivations. The plots were each 1/20th acre.

The experiments were conducted on two classes of soil, a red sandy loam (Dalys B), a light limestone rubble (No. 16). The results are given in the following table:—

ROSEWORTHY AGRICULTURAL COLLEGE.

Cultivation of Fallow Experiments.

Treatment.	I. Dalys B. (Sword). Results on Red Sandy Loam.	II. No. 16 (King's White). Results on Light Limestone Rubble.
	Bush. lbs.	Bush. lbs.
A. Routine fallow, five workings	30 10	26 38
B. Missed one cultivation in late summer	**28 28**	27 42
C. Missed one cultivation in autumn	**25 54**	**20 40**
D. Missed one cultivation in early summer	**25 58**	26 0
E. Missed two cultivations in i. early summer	**23 46**	**19 56**
ii. autumn	—	—
F. Missed two cultivations in i. late summer	**23 52**	**19 12**
ii. autumn	—	—
G. Missed two cultivations in i. early summer	**25 30**	25 4
ii. late summer	—	—
H. Missed three cultivations in i. early summer	**22 20**	**20 40**
ii. late summer	—	—
iii. autumn	—	—

I. Dalys B—(Sword) S.E. = 2.7 %. Significant Difference 84lbs. per acre.
II. No. 16—(Kings White) S.E. = 3.1 %. Significant Difference 96lbs. per acre.
Significant results in comparison with the standard of Routine fallow, five workings, are in block type.

The conclusions to be drawn from the results are that the routine fallow with five workings was significantly superior to all other treatments studied in Dalys B, and in all cases, the neglected fallows were significantly inferior to the rest. In the same paddock, Dalys B, the fallows which missed the autumn cultivations were in all cases inferior to the other preparations. The early summer cultivation was of significant importance as indicated by the results from treatment D which did not receive this cultivation, whereas it does not appear to have had the same importance when it was missed in association with another cultivation (treatment G) except that it is again significant when it is missed in association with the autumn cultivation (treatment E). The logical conclusion is that in 1934 the autumn cultivation was the most important and critical one carried out. The late summer cultivations appear to have had little effect on the yields, though the fallow that missed this one cultivation alone (treatment B) gave a significantly lower return than the routine treatment A.

The Stud Plot Stripper taking off a long row of Wheat. Note the cocky chaff blowing out at the back as the machine moves forward.

The results from No. 16 (Kings White) on light limestone rubble agree fairly closely with those from Dalys B in so far that missing the autumn cultivation was the cause of a significant decrease in yield. The difference in this case is much greater than in Dalys B and may be attributed to the earlier and more rapid weed growth on the lighter soil. In this case, also, the early summer cultivation is shown to be more important than the late summer cultivation.

A scrutiny of the yields obtained under the different treatments reveals some interesting information. Firstly it is noticed that the good fallow outyielded the neglected fallow by approximately 5bush. on the sandy loam and 6bush. on the rubble—a loss of approximately 15s. and 18s. per acre respectively on the basis that wheat is worth 3s. per bush. to the farmer. The cost of the three cultivations must be offset against the profit from the good fallow. This varies in different districts but taking everything into consideration it is estimated that each cultivation at the College costs approximately 1s. 6d. per acre. Thus the grazing value of the neglected fallow would have to be more than 10s. per acre if the loss in yield were to be compensated by the feed obtained from the extra weed growth.

Further analysis of the results shows that the autumn cultivation was all important in 1934, both on the sandy loam and on the rubble, irrespective of the number of times the land had been cultivated before the autumn. Neglect of the summer fallows was more important on the sandy loam than on the rubble, but it will be necessary to repeat the experiment for a number of years before definite conclusions can be formulated on the relative importance of the summer workings. There can be no doubt that results of this kind of experiment are very materially affected by conditions of soil and climate and it would be folly to suppose that the results obtained from experiments at the College are applicable in all cases. Actually they would only apply to areas of similar environmental conditions on the same class of mallee soil. This, however, does not detract from the value of such work, for it is being conducted to demonstrate, as forcibly as possible, the importance of good fallowing methods and to show that neglect of fallows in wheat growing means, in almost all cases, monetary loss.

TRIALS WITH SULPHATE OF AMMONIA.

During the last few years the value of sulphate of ammonia for stubble crops has been demonstrated under certain conditions. Generalisations from particular instances have led to the wider use of this fertiliser for stubble crops, but there are several factors which must be taken into consideration before the general use of such fertiliser can be advocated.

1. In the first place a much better response from nitrogenous fertilisers is to be expected in high rainfall districts than in districts where the rainfall is below 20in.

2. Secondly, nitrogenous fertilisers might quite conceivably increase the vegetative growth and handicap the crop from finishing and filling its grain well under short seasonal or poor finishing conditions; such conditions prevail as the rule rather than the exception in many cereal districts of the State.

3. Significantly increased returns may accrue but they may not be sufficient to cover the costs of the sulphate of ammonia.

4. On wheat land in good heart which has been farmed well on a wide rotational basis and liberally supplied with superphosphate a good cover of leguminous pasture can be expected when the paddock is rested as ley land. Under such conditions a payable response from nitrogenous fertilisers may not be obtained.

5. On wheat land which is being over-cropped and where quick returns are taken to be "the be all and end all" of the agriculture of the farm, sulphate of ammonia will likely give a payable response on stubble land.

6. Nitrogenous fertilisers have no beneficial residual effects as has superphosphate and unless the season is such that payable returns are possible, the application of sulphate of ammonia is lost.

7. More knowledge of the effect of sulphate of ammonia on the fertility level and physical condition of the soil is necessary before the unqualified use of the fertiliser can be advocated. It is necessary for farmers to think in terms of mixed farming rather than in hay or grain returns. It is quite conceivable that the drain on the fertility level of those soils upon which sulphate of ammonia gives positive results, might be seriously reflected in the subsequent pasture, even though the rate of application of superphosphate has not been reduced.

Results obtained at the College during the past two seasons substantiate the assertion that such points as the above should be given close and careful study before embarking on the regular use of sulphate of ammonia for stubble crops. The results obtained are tabulated below:—

ROSEWORTHY AGRICULTURAL COLLEGE.

TRIALS WITH SULPHATE OF AMMONIA ON STUBBLE CROP—PRIOR BARLEY.

Seasons 1933-34

Treatment per Acre.	Grain.		Hay.
	Yield per Acre, 1933.	Yield per Acre, 1934.	Yield per Acre, 1933.

Treatment per Acre.	Grain. Yield per Acre.	Hay. Yield per Acre.
	Bush. lbs.	Tons cwt. lbs.
No manure	29 21	2 2 63
1cwt. Superphosphate	30 36	2 6 17
1cwt. Sulphate of Ammonia	33 25	2 10 15
1cwt. Super. and ½cwt. Sulphate Ammonia	36 2	2 14 39
1cwt. Super. and 1cwt. Sulphate Ammonia	35 29	2 15 60
1cwt. Super. and 1½cwt. Sulphate Ammonia	33 27	2 10 54

S.E. = 4.2 % for grain. Significant Difference = 112lbs. per acre for grain.
2.8 % for hay. Significant Difference = 320lbs. per acre for hay.

A perusal of the results from the trials clearly demonstrates that under College conditions the heavier dressings of sulphate of ammonia are uneconomical and in some instances have even caused a reduction in yield. This reduction is most marked in the grain yields of Prior barley in 1933. It will be remembered that the finish of this season was particularly severe and those plots which received dressings of sulphate of ammonia, produced a pinched sample of grain and a fluffy hay of low feeding value. This accentuates the emphasis which must be given factor 2 in the preliminary discussion on this subject.

A dressing of 1cwt. of super and ½cwt. of sulphate of ammonia gave significant increases over 1cwt. super only in oaten hay and grain in 1933 and for barley grain in 1934, and such increases may have been sufficient to show a small profit on the cost of treatments, but against this must be offset the definite loss on barley grain and hay in 1933.

It might also be pointed out that a dressing of 1cwt. superphosphate gave no significant increase in yield as compared with the unmanured plot, but this may be attributed to the residual superphosphate in the College paddocks. This is sufficiently high to support an unmanured crop on stubble land equally well as would a dressing of 1cwt. of superphosphate. It is highly probable, however, that the following crop on the unmanured plot would show a significant decrease in yield if superphosphate were not applied. The residual effect of a fertiliser is most important in its bearing on subsequent pastures. It is a well known fact that the residual effect of sulphate of ammonia is negligible—in fact it is probable that heavy dressings might have a deleterious effect of a similar nature to that of overcropping. The heavier vegetative growths which are obtained in some instances must add to the strain upon the fertility level of the soil. On the other hand, liberal dressings of superphosphate encourage a luscious mixture of legumes and pastures; once the legumes are established there is no need for nitrogenous fertilisers. This explains the results obtained at the College. *Owing to the regular use of superphosphate, pastures rich in legumes and with a high carrying capacity have been built up; consequently the general fertility level in the soil is higher in every respect and it is not to be wondered at that the application of sulphate of ammonia fails to produce those startling results which have been obtained on soils in not such good heart, which are virtually low in available as well as potential nitrogen.*

Before the use of sulphate of ammonia can be recommended for the major part of the wheat growing area of South Australia, extensive rotation experiments are required. It is futile to draw conclusions on one or two year's results from experiments in picked localities, particularly as results are generally presented in terms of grain or hay yield only, although it is conceded by the College that it may be quite possible that in the better class wheat soils, light dressings of sulphate of ammonia, in addition to the usual dressings of superphosphate might give a profitable return. Results at the College have shown that applications of heavy dressings of sulphate of ammonia are risky, particularly in those districts which are likely to be subjected to a severe finish.

It has been proved beyond doubt that the yielding ability and carrying capacity of the farm can be built up by the liberal use of superphosphate, livestock and judicious cropping and this is the policy which has been advocated by the College and will be advocated in the future unless, of course, later work and results can lend greater *agricultural significance* to the use of nitrogenous fertilisers on the stubble crops of the main wheat growing areas.

TOBACCO IN MURRAY IRRIGATION AREAS.

[R. E. C. GILES, Tobacco Instructor.]

Experimental tobacco plots around Barmera and Loveday show considerable improvement upon anything previously conducted in this area. Light Virginian types are being grown this season. Leaf curing operations will be conducted in the barns made available by the Department of Agriculture for this purpose.

Section of Mr H. Wilkinson's Experimental Plot at Loveday.

* Potatoes excluded.

The stem above ground bears only a single produced leaf, devoid of cormils in its axil, above which it becomes continuous with the slender axis of the inflorescence. The stem is often flexuose and bears but one or two branches. Flower clusters are relatively few in number and situated towards the ends of the stem and its branches. The flowers are at first enclosed within the spathe leaves and later emerge and open. Usually only a single flower is open at a time, the size being almost double that of the flower of *H. miniata.*

Means of Spreading.—Both species of Cape Tulip have a wide distribution in this State, and while both are equally injurious to stock, it is uncertain which of the two is to be considered the more serious as a weed. Owing to the production of cormils the Two-leaved Tulip would seem to be the more difficult to get rid of when once firmly established, but it does not appear to spread as rapidly as the other, and so may possibly be less efficient as regards reproduction by seed. The chief method of natural spread is by the seeds which, being small and light, are easily carried by wind, &c., and may germinate at considerable distances from the sites of their formation.

The development, below the ground, of corms and cormils leads, under strictly natural conditions, to the consolidation of the area occupied and to some slight degree of local spread. The formation of cormils above ground in the axils of the aerial leaves in *H. miniata* also facilitates the spread of the plant locally. When the aerial parts die down, and subsequently become withered and dry, these cormils are set free and may germinate at some distance from the parent. Thus, even under natural conditions, the Tulips are well equipped to compete successfully with other plants.

Conditions of settlement add to the advantages of the Cape Tulips in this respect. Being usually avoided by grazing stock they may grow unchecked on pasture land where useful species are being eaten out. While the weeds do not grow so well on cultivated land, tillage operations may, by spreading the corms and cormils, increase the areas infested. Some measure of control may be effected by placing badly infested land under crop, but eradication is not effected thereby, and the weed is certain to reappear when such land is restored to pasture.

Other methods whereby the Tulips may be passively spread are the transport of cormils in mud on the feet of animals or on farm implements, the cartage from place to place of earth containing seeds or cormils, the accidental distribution of the latter with seedlings, bulbs, &c., of garden plants, and so on.

Effects on Stock.—The special importance which attaches to the Cape Tulips as weeds of pasture land is due to the known poisonous nature of both species. The poison occurs in all parts of the plants, both in the corms and leaves, and irrespective of whether the latter are fresh or dry. While animals soon become accustomed to the presence of the plants and avoid them, heavy mortalities are by no means infrequent during the winter months, especially when green feed is scarce and where stock have been brought on to Tulip-infested country from districts where the weed does not occur.

The symptoms of Cape Tulip poisoning are partly those of an acute gastro-intestinal irritant, and partly those of a cerebral depressant or narcotic, such as would be caused by the absorption of some active toxic principle. Examples of the first are abdominal pain, diarrhoea, and, if large amounts of green leafy material have been ingested, distention of the stomach with gas, the symptoms increasing in severity and resulting in colic, frequent scouring, great weakness and prostration. The nervous symptoms are indicated by dullness and depression. The precise nature of the toxic substance is not known in the case of *H. collina* or *H. miniata,* but it is probably an alkaloid. Rindl (1924) extracted an alkaloid, which he termed *homeridine,* from *Homeria pallida,* another African species with yellow flowers. According to Rindl, this substance, in large doses, behaves as a cardiac poison, and, in small doses, has an action resembling that of digitalis, without, however, the cumulative effects of the latter substance.

Death may occur rapidly, within 12 hours or less after ingestion of the leaves, or the animals may linger for several days. Where recovery takes place the nervous symptoms do not disappear for some time.

The following, which is quoted by Hutcheon (1900) from the ***Florae Capensis Medicae,*** by Dr. L. Pappe, describes a case of poisoning in human subjects due to ***Homeria collina***:—

> "A Malay woman and three children ate a small basin full of the bulbs of this plant at about 8 p.m. About 1 o'clock in the morning the woman awoke with severe nausea and severe vomiting and found the children similarly affected. She endeavoured to call for assistance but was unable to leave her bed, &c. The two eldest children died, the woman and the youngest child recovered."

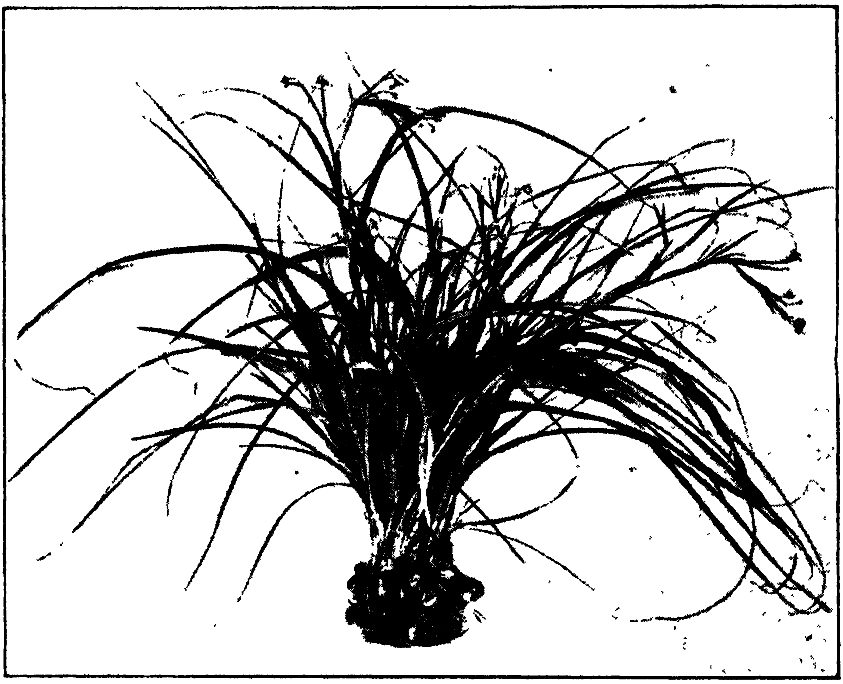

Fig 3 —Two-leaved Tulip. Photograph of a clump of plants, showing the crowded habit, due to cormil formation.

Control and Eradication.— The wide distribution of the Cape Tulips, their habits of growth and multiplication render their State wide control a problem of considerable difficulty. Owing to the relatively small surface presented by the aerial parts, the toughness of the foliage, and the inaccessible position of the corms, these plants tend to be more resistant to chemical sprays than most other weeds. The method of perennation by means of underground corms, and the relative immunity they enjoy from being eaten down by grazing stock during the growing period gives them a marked advantage in competition with other pasture plants. Small patches can be treated by sprays, but high concentrations of weedicide are necessary; another difficulty is that by the time the plants have come into flower and can be clearly recognised a new generation of corms has been formed underground. Unless these are destroyed there will be just as luxuriant a growth of the Tulips the following year. The time of spraying is doubtless important, and one application at least should be made early in the growing season, soon after the plants have appeared above ground. Young foliage is obviously more vulnerable to attack than full-grown leaves, and on land known to be badly infested with Tulips an application of weedicide during the early stages of growth might be productive of more effective results than more liberal treatments, when the plants are more advanced. The old saying—"Out of sight, out of mind"—is nowhere more vividly illustrated than in the case of the bulb-forming perennial weeds which appear above ground during winter and spring, and are lost to sight for the rest of the year. Cape Tulip is a source of trouble every year, and invariably attracts attention, but only when the plants are well advanced and when most of the harm has been done. We are impressed with the importance of finding some method of eradicating this weed when cases of poisoning are brought to our notice and when the plants are visible above ground, but we are apt to turn our attention to other matters when the dry season approaches and the plants disappear from view. But it would be well not to lose sight of the fact that Cape Tulip is due to appear again and will almost certainly cause poisoning of stock during the coming year, and that, where eradication measures are to be undertaken, an early start might make all the difference between success and failure. Spray treatments, in order to be really effective, would probably require to be carried on over a number of years, with several applications during each period of growth.

Where the plants are already in flower, probably the most satisfactory thing to do in the case of small patches is to dig out and burn as many of the plants as possible, taking every precaution against spreading the corms and cormils during the process, and to mark out the patch for treatment with weedicide early in the following season, applying further treatments during that year. In all cases seed production should be prevented whenever possible.

Cultivation is a useful method of reducing the vigour and density of the weed, and on large areas which are badly infested it may be necessary to plough up the land and, after repeated cultivations, to place it under crop. While permanent eradication will not be accomplished by this means, some measure of control will be established. Unfortunately this is not always practicable. In the absence, as yet, of any effective and inexpensive means of eradicating Cape Tulip from large areas of pasture land, efforts should at least be made to prevent it from spreading to new areas by destroying any stray plants which appear, and, as far as possible, to check the growth and seed formation of plants on more densely infested areas.

CARBONATE OF LIME.

NEGATIVE RESULTS IN WHEAT-GROWING EXPERIMENTS.

[By R. C. Scott, R.D.A., Supervisor of Experimental Work, Department of Agriculture.]

Experiments dealing with the use of carbonate of lime have been conducted at a number of centres and were designed with the object of showing the value of carbonate of lime as a fertiliser for cereal crops.

Lime is an essential plant food, but on the other hand the amount removed by plants is very small, and it is exceptional to find a soil so deficient in this substance as to limit plant growth. At the same time, lime plays an important part in agriculture, because of its influence on the physical properties of the soil. It leads to an improvement in the texture of what would otherwise be sticky heavy clay land. It increases the water-holding capacity and modifies the looseness of sands, whilst it also has influence in neutralising the harmful conditions associated with sour or acid soils.

However, it is not from the point of view of carbonate of lime as an improver of the physical properties of soils that this report has been compiled, but to deal more directly with its value as a plant food for crops seeded on fallow land.

Notwithstanding the fact that no benefits could be anticipated, experiments dealing with this aspect became necessary because of the persistent advocacy of the use of carbonate of lime as a fertiliser by certain interested parties. As a result, a number of farmers have purchased carbonate of lime under a misapprehension as to its manurial value, and it was only by obtaining actual yields from a series of experimental plots scattered throughout the agricultural areas of the State, together with the field demonstrations thus provided, that the true position of this material could be shown.

OUTLINE OF EXPERIMENTS.

Accordingly, arrangements were made with a number of farmers to plant experimental plots under the supervision of officers of the Department of Agriculture. In all, seventeen plots were planned. They extended from Booleroo Centre in the North, throughout the Lower North and Murray Flats to Strathalbyn in the South.

At every centre four plots of wheat were planted on fallow land, each being approximately two acres in area, and receiving the following treatment:—

Plot 1—No manure.
Plot 2—1cwt. of carbonate of lime per acre.
Plot 3—1cwt. 45 grade superphosphate per acre.
Plot 4—1cwt. 45 grade superphosphate together with 1cwt. of carbonate of lime per acre.

In this experiment three comparisons were possible, namely:—

That between the yield from the "no manure" and the 1cwt. of carbonate of lime plots.

That between the yield from the 1cwt. of superphosphate and the 1cwt. of carbonate of lime plots.

That between the yield from the 1cwt. of superphosphate and the 1cwt. of superphosphate plus 1cwt. of carbonate of lime plots.

AGRICULTURE IN THE TEMPERATE AND SUB-TROPICAL CLIMATES OF THE SOUTH.

A Report by the Deputy Director of Agriculture (W. J. Spafford) to His Excellency Sir Winston Dugan, K.C.M.G., C.B., D.S.O., Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia. Mr. Spafford took a brief tour of portions of the principal agricultural countries in the same climatic zones as the settled portions of Australia, in fulfilment of the appointment as Honorary Commissioner, conferred upon him by His Excellency, to inquire into and report upon the Production and Preparation for Marketing of Agricultural Products, including Crops and Livestock in South America, South Africa, and New Zealand.*

(*Continued from page* 801.)

URUGUAY.

The smallest Republic in South America is Uruguay, and the country is of particular interest to others living in the cool parts of the Southern Hemisphere because her existence depends upon agricultural production. Although not so well favoured as some other countries, in so far as soils are concerned, the whole country receives a liberal and well-distributed rainfall, and is not subject to frequent droughts of any severity. Furthermore, Uruguay is very favourably situated for exporting her surplus agricultural products to either Europe or North America.

THE COUNTRY OF URUGUAY.

Located on the eastern side of Argentina, and separated from this country by the Uruguay River, the Republic of Uruguay is a small country almost pear-shaped, with the portion somewhat like the stem end of a pear being at the point where the 30th parallel of south latitude crosses the Uruguay River. The greatest length of the country runs from the north-west corner, in a south-easterly direction to 35° south latitude, a distance of about 370 miles, whilst the greatest width at right angles to the length is more than half-way down the country and extends for about 300 miles. The total area is 72,153 square miles.

The great bulk of the country is steeply undulating to hilly, the hills rising abruptly from valleys, and being more or less table-topped. The hills occupy a much greater area than do the valleys and lower plains, and in most cases are very stony, and rather similar in appearance to the stony hills so typical of South Africa. Although a hilly country, few, if any, of the hills reach a height of 2,000 feet, so that Uruguay cannot be described as a high country.

It is generally understood that most of the Republic is suitable for agriculture, and this is to be expected, because there is very little land too high for farming purposes. Most of the waste land is stony, or the actual area occupied by lakes and streams. On the hills the soils are mostly very shallow and only fairly fertile, but in the valleys, good, rich chocolate soils capable of growing crops and luxuriant pastures are usually to be found. In the fairly extensive strip of arable land along the southern end of the Republic, and extending up the Uruguay River to Salto, deep, chocolate-coloured clayey soils, resting on impervious clays, are generally present, and these being obviously fertile soils should produce very heavy crops indeed, when properly treated.

Rivers and creeks form a network all over the country, and besides this source of water, the underground supplies are really plentiful, even at shallow depths, and in many places sub-artesian water is to be got at depth. The big Uruguay River, which is some 940 miles in length, is navigable up to the rapids at Salto, which is somewhere about 200 miles above the mouth, and over 300 miles above Montevideo, the capital of the country, which is located on the River Plate.

---

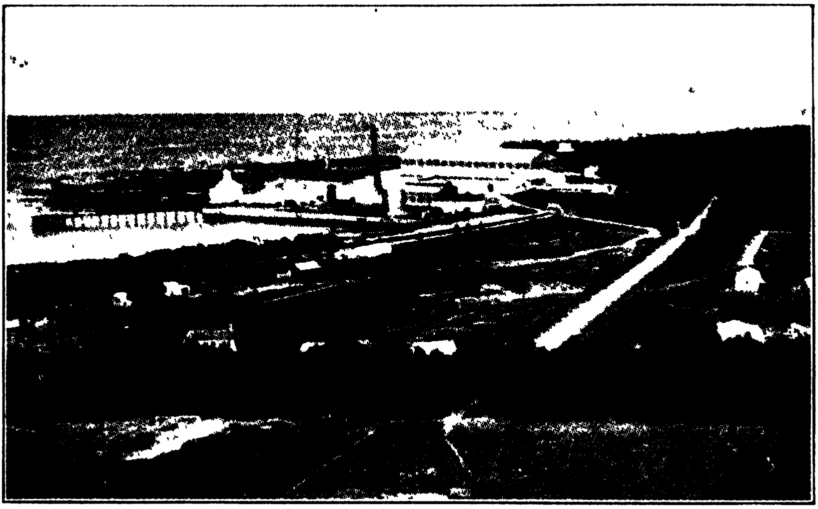
*Tour made in the company of Col. C. P. Butler ("Yattalunga," of the *Advertiser* and the *Chronicle.*)

Few forests of any kind exist in Uruguay, and, as a matter of fact, other than those planted for shade and breakwinds, trees are rare, except along rivers and creeks.

The climate is very healthful for people and domesticated animals, and really favourable for most crops, the summer being sunny and fairly warm in the daytime, but relatively cool at night, and the winters prove, practically always, to be fairly mild.

RAINFALL OF URUGUAY.

The average annual rainfall does not vary a great deal over most parts of Uruguay, for although in one locality it approaches 50 inches, the great bulk of the country gets about 35 inches. The following table shows the average annual rainfall for the two years 1933 and 1934, for the nineteen political departments into which the country is divided:-



[From *La Industria de las Carnes en el Uruguay.*

A Fairly Extensive Saladero, or Salting-down Works, in Uruguay.

Throughout Uruguay and Southern Brazil enormous quantities of beef are salted and sun dried, and when preserved in this way is known as Xarque (Sharkey). Most of the Xarque made in South America is used in Brazil.

Average Annual Rainfall of Uruguay, 1933 *and* 1934.

	Inches.
Artigas	41.3
Salto	34.8
Rivera	47.2
Paysandú	34.2
Tacuarembó	39.0
Cerro Largo	41.4
Rio Negro	34.7
Durazno	39.3
Trienta y Tres	42.0
Soriano	39.9

Lavalleja	34.6
Rocha	35.5
Colonia	38.6
San José	34.3
Canelones	34.5
Maldonado	34.8
Montevideo	32.9

Not only is the country well served with a liberal rainfall, but it is very evenly distributed throughout the year. There is an appreciable variation from month to month in the quantity of rain recorded, but no month is a dry month, and of the four seasons of the year, autumn (March to May) receives about 30 per cent. of the total, winter (June to August) about 20 per cent., and spring (September to November), and summer (December to February) about 25 per cent. each.

THE AGRICULTURE OF URUGUAY.

The importance of agriculture, and particularly livestock farming, to Uruguay, is readily seen by a look at the export figures of the country, and the next table presents the percentage value of all the principal exports in the year 1932:—

Value of Exports from Uruguay in 1932.*

Various articles	4.15
	100.00

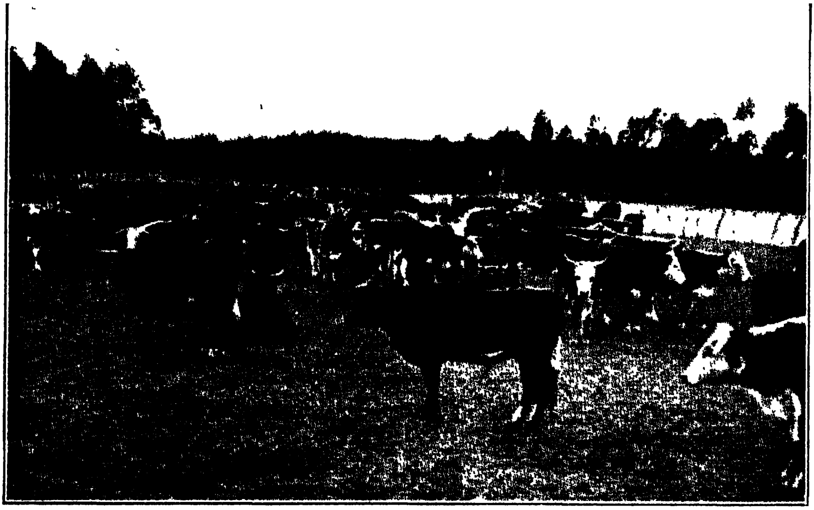
*Síntesis Estadístico de la República Oriental del Uruguay.

These figures show very clearly why Uruguay is generally described as a grazing country, because over 82 per cent. of the value of her exports consists of livestock products, nearly every bit of which is derived from pastures. Very little pig products are exported, and practically no hand-feeding of meat-producing animals with concentrates, is practised anywhere in the country.

It appears that not much attempt is made to improve the natural pastures of Uruguay, either by establishing useful pasture plants or by fertilising existing pastures, and as a consequence, although the pastures are evergreen in most parts of the country, there is a period in every year when the grazing animals lose their condition. It is usually stated that Lucerne will not grow well in the country, but although not making equal growth with that of Argentina, patches of the crop seen here and there throughout the Republic were quite fair, and make it appear that the crop can be successfully grown in most places where the land is arable. Even cereals are not grown for grazing by fattening livestock, nor have there been many attempts to establish pasture plants proved to be suitable in similar climatic conditions. The shallow soils, resting on stones, so usual on many tablelands, grow rather stunted pastures which appear to be of fair quality, the grasses consisting largely of Couch or Bermuda grass (*Cynodon dactylon*), *Paspalum dilatatum*, Water Couch grass (*Paspalum notatum*), and another rather short fine-stemmed grass, whilst leguminous plants are of rare occurrence. In the valleys, most of which have rich, chocolate-coloured soils, the pasture growth is luxuriant. The shortage of legumes amongst the pasture plants is noticed by landholders, and it appears to be generally recognised that the best fattening pastures are those containing a fair proportion of leguminous plants, the principal ones which have become established in places are Toothed Medic (*Medicago denticulata*), and Spotted Medic (*Medicago arabica*).

THE FARM LIVESTOCK OF URUGUAY.

In the year 1860, Uruguay was maintaining about three and a half millions of cattle, about two millions of sheep, and about a half million of horses, and just a few thousands of other kinds of stock, but within 50 years cattle had increased to over 8,000,000 head, sheep to nearly 26,300,000, horses remained at about the half million, pigs had multiplied to 180,000, and the less important farm livestock, such as goats to about 20,000, and asses and mules (together) to about 22,000 head.



[From *La Industria de las Carnes en el Uruguay*.

Cattle Awaiting Slaughter in Uruguay.

Hereford is the predominant breed of cattle in Uruguay, about 63 per cent. of the cattle of the country being of the Hereford breed. Cattle Tick, deficient pastures, and lack of care in breeding tend to keep down the quality of the cattle

Between the census periods of 1908 and 1930 there has been a general decline of all kinds of farm livestock except pigs and poultry, and it is generally recognised that the cause of the decline is the great increase in crop growing that has been brought about during the same period. The decrease in cattle numbers, which amounts to about 1,000,000 head, is alleged to be caused by the increase in the number of sheep being maintained, but however true this may be in recent years, it can hardly be the principal reason for the reduction, because there are over 6,000,000 sheep fewer now than there were in 1908. Sheep declined rapidly from 26,286,296 head in 1908 to 11,472,852 head in 1916, but recovered to over 20,000,000 head by 1930. The pig population has changed from about 180,000 in 1908 to about 308,000, and poultry numbers have been increased during the same time from 3,143,526 to 4,927,196.

Details of the changes in numbers since the census of 1860 are shown in the table following:—

Number of Livestock in Uruguay Since 1860.

Animals.	Census Year.					
	1860.	1900.	1908.	1916.	1924.	1930.

CATTLE IN URUGUAY.

There is no comparison between the cattle produced in the adjoining countries of Argentina and Uruguay, those of the former being noted for their high quality, whilst the cattle of Uruguay are rather poor. Of animals of which the breeding is known Herefords predominate, and of the 7,128,000 present in 1930, about 4,500,000 were of the Hereford breed, and about 2,000,000 of the Shorthorn breed. This state of affairs appears to be due to the fact that the Cattle Tick is present throughout Uruguay, and the pastures on much of the country are rather too scanty for the rapid-maturing Shorthorns. The absence of a high proportion of leguminous plants in the pastures, the neglect of frequent importations of well-bred, high class bulls from Great Britain, and the failure to grow fodder crops or to supply concentrates to the growing beasts, preclude all chances of the cattle reaching the high standard attained by Argentina.

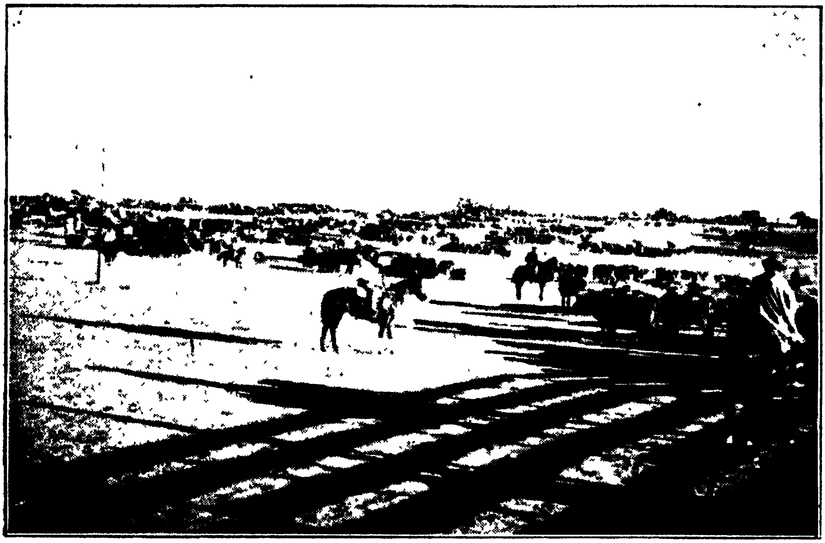
SALE OF CATTLE IN MONTEVIDEO.

Montevideo, the capital city of Uruguay, has a population of about 700,000 people, and has three large frigorificos exporting beef to overseas ports, and so the cattle requirements for local consumption and export are fairly considerable. To meet the demand a cattle sale is held five times a week, from 8 a.m. to 11 a.m., and is conducted in a unique manner, for the various mobs assemble in an open space without yards of any kind, and are kept in positions from 6 to 10 yards apart, by horsemen. Calves, up to almost 12 months of age, are placed in yards on the outskirts of the principal sale area, but all older animals are kept in the open throughout the progress of the sale. The herds are comprised of from 3 to 70 or so head of cattle, and the ingenuity of the horsemen in keeping the



Cattle Sale in Progress in Montevideo, Uruguay.

Mobs of cattle, of from 3 to 70, are kept apart by horsemen throughout the period of the sale, despite the fact that the buyers and their clerks, mounted on horses, ride through the groups when negotiating a purchase.

[From *La Industria de las Carnes en el Uruguay.*

Driving Cattle on to a Weighbridge after being Sold in the Montevideo Sale-yard.

As is usual throughout South America, all animals for slaughter are sold by liveweight, and so large weighbridges are necessary at all important sale-yards. On the town side of the sale-yard at Montevideo two large weighbridges, each capable of taking fairly big mobs of cattle at a time are provided, and so little delay occurs in getting the cattle on the road towards the frigorificos after being purchased.

herds separated, one from the other, is remarkable. Buyers and their clerks, all on horseback, ride into the herds to get a proper look at them, and then haggle over the price with the seller. Now and again a beast breaks away, but several horsemen give chase, and the animal is brought back to its herd and soon settles down. Several hundreds of horsemen are necessary in such a market, as everything is done from horseback. Saddled horses can be hired at the site for the use of anyone interested in any phase of the sale. It has become customary for different types of cattle to be held in particular portions of the area, but this is not obligatory. All sales are made subject to delivery at the frigorifico for which the cattle were purchased, and immediately a sale is made the herd is weighed, and then driven to the frigorifico. As all mobs leave by the same road, several lots are travelling along at the one time, separated one from the other by 2 or 3 horsemen, and although only a few yards apart rarely get mixed together. Cattle unsold by 11 a.m. are removed from the area and may be offered for sale on next sale day. Such a sale is only possible with the quietest of cattle.

SHEEP IN URUGUAY.

Sheep products constitute the most important line of production of Uruguay, and from an export point of view are of greater value than any other particular group of articles, including cattle and their derivatives.

[From *Bulletin of the Pan American Union.*

Sheep in the Yards of a Frigorifico at Montevideo, Uruguay.

All animals visible in the illustration are of the long-woolled type of British sheep, to which class most of the sheep of the country belong, although at one time Merinos were popular

In numbers, sheep reached their peak in 1908, when 26,286,296 head were maintained, but shortly after this time the flocks receded to less than half, but have again increased to somewhere about 20,000,000 animals.

Some years ago Merino sheep were quite prominent in Uruguay, and were then encouraged because of the fine type of wool being produced, but even before the war they were losing their popularity. As recently as 1924, about one-third of the wool of the country was of the Merino type, but ever since that time the proportion of this kind of wool has become less and less, being replaced by the coarse crossbred type of wool. Even though the finer types of wool are not produced in very great quantities, wool is the most important for export purposes, of all the products of the country, and in value is worth over 32 per cent. of all exports. As considerable quantities of mutton and lamb are also exported, sheep are of the utmost consequence to Uruguay in her present stage of development.

*Not including farm slaughterings.
†Average, 1926 to 1930.
‡Average, 1925 to 1929.

Most of the sheep seen in the market and on farms belonged to one or other of the long-woolled breeds, or were crossbreds containing a lot of long-woolled blood. Of pure-bred sheep, Merino, Lincoln, and Romney Marsh are the most popular, and although Uruguay has a fair reputation for sheep, all of the animals seen, with the exception of a few Romney Marsh, which were of fair quality, were poor in type, and at the same time not carrying much condition. Some good Romney Marsh and fair Merinos were heard of, but none that could be classed as such were encountered. In the sheep market where animals for slaughter are sold, as to be expected most of the mature sheep were of a long-woolled type, but the great majority of the lambs were also of this type, although a fair sprinkling of lambs by Shropshire sires were in evidence, and were of good mutton type, but a bit poor in condition.

PIGS IN URUGUAY.

Pigs are not yet very prominent in Uruguay from an export point of view, but they have made a rapid and regular increase in numbers ever since the census of 1860, and appear as though they will become of great importance to the country in the future. The animals seen were mainly of the Duroc Jersey or Poland China breeds, or crossbreds containing one or both breeds in their make-up, but although in good order were much too fat, and showed no indication of an effort having been made to modernise the type.

POULTRY IN URUGUAY.

Poultry keeping is popular in Uruguay and the number of birds being maintained is increasing with time. Poultry for table purposes take prominent place amongst the foodstuffs of the people, and markets are generally well stocked with birds for killing. All sorts of mixtures of breeds appear to be in the breeding of most of the fowls seen, and the only two pure breeds at all plentiful are Plymouth Rocks and Rhode Island Reds. Of turkeys, which kind of poultry is to be seen in most parts of the country, Blacks appear to be very prevalent. Muscovy ducks are presented for sale in large numbers in the markets, and also another breed very similar in type, but having white body, grey wings, and a much cleaner head than the Muscovy.

CROPS IN URUGUAY.

From an agricultural point of view, Uruguay is an important livestock country, but crops do not occupy such a prominent position, particularly as far as exports are concerned Nevertheless, the country produces sufficient for her own requirements, of almost everything, and exports a little of several of the different kinds of crops.

Wheat is easily the most important of the crops commonly grown, the area seeded each year exceeding 1,000,000 acres. Next to wheat comes maize, with a little over half a million acres a year, and then linseed which is grown on about 400,000 acres a year. Other than these crops, none occupies an extensive area, although in almost all instances sufficient is produced for local consumption requirements.

The progress of the principal crops of the country, except citrus fruits and vines, is shown in the following table:—

‡Síntesis Estadístico de la República Oriental del Uruguay.
NOTE.—In translation hectarea taken as 2.47 acres, and quintal as 220lbs.

Of important crops not shown in the above table, citrus fruits are becoming prominent, slowly but surely. It is generally recognised that really good quality citrus fruits can be grown with certainty in almost all parts of the Republic. The climate is ideal for these fruits, water is plentiful, and there are considerable areas of sufficiently fertile soils in many parts of the country to make a flourishing industry of citrus-fruit production. The natural conditions are favourable, and the relatively close proximity of the shipping port of Montevideo to the important European markets, makes it appear inevitable that Uruguay comes into the citrus-fruit trade with some force in the future.

WINE-MAKING IN URUGUAY.

Vine-growing for the production of wine has been an important agricultural activity in Uruguay for a long while, and the progress made in the past 50 years or so has been really considerable. The area planted with vines for wine making is about 30,000 acres and the production of wine is about the 12,000,000 gallon mark.

GENERAL.

Uruguay appears to have great possibilities, relative to her size, as an agricultural country, but before this can be brought about very considerable improvements must be made in her practices, many of which are rather old-fashioned. Soil-cultivating teams consist largely of yokes of oxen, varying between 2 and 8 animals, depending upon the job being done, and one plough team seen had 2 oxen on a pole, and a horse as a leader, with a boy riding on the leader to guide the team. Some of the market gardens, orchards and vineyards are really well cared for, but others were rather neglected, and the annual growth of most vines and fruit trees was far from luxuriant. The maize crops were in all stages between young growth about a foot in height and ripe crops, but all were poor compared to those seen in the adjoining country of Argentina. With the exception of pigs, most of the animals for slaughter—cattle and sheep—as seen on farms and in sale yards, were of deteriorated type, or low in condition. This state of affairs cannot last for long, because the people are being educated, and so efficient is the system that there are less illiterate in Uruguay than in most South American countries. The compactness of the country, the regularity of soil and climate, the favourable climate for agricultural purposes, the prevalence of easily obtained water supplies, the efforts being made to educate the people, and the proximity to the European markets make it appear that this small Republic of Uruguay will be heard of in the future as an agricultural country of some note.

SUMMARY OF IMPRESSIONS GAINED IN URUGUAY.

1. The small Republic of Uruguay is almost pear-shaped, and is about 370 miles long by 300 miles in width.

2. The great bulk of the country is steeply undulating, the hills, which occupy a greater area than the valleys, being stony. Few, if any, of the hills reach a height of 2,000 feet.

3. Most of Uruguay is suitable for agriculture, but the high tablelands are stony, whereas the valleys are very fertile.

4. Water is plentiful in Uruguay.

5. The climate of the Republic is very favourable for livestock and crops, and the rainfall is plentiful and well distributed.

6. Uruguay is essentially an agricultural country, and is particularly important as a producer of livestock, nearly all of her returns for exports being obtained from this source.

7. At present, practically all livestock are carried on natural pastures, very little having been done to improve the pastures, and few attempts made to practise hand-feeding.

8. A great increase in the numbers of all farm livestock was brought about up to the 1908 Census, but since that time, all kinds have declined, except pigs and poultry.

9. Cattle are maintained in great numbers in Uruguay, and the Hereford breed predominates, the pastures being a bit too scanty for fast-growing Shorthorns. Large numbers of high-class cattle are not to be seen in Uruguay, although climatic conditions are similar to those of the neighbouring country of Argentina, where cattle are so good.

10. The cattle sale held five times a week in Montevideo is unique, in that all mobs being offered for sale are held as separate groups by horsemen, in the open without yards.

11. Sheep husbandry is the most important activity of the country, and from an export point of view, sheep products are of greater value than any other particular group of articles.

12. At one time it appeared that Merino sheep were likely to become really prominent in Uruguay, but of recent years the popularity of the breed has declined in favour of long-wools and crossbreds.

13. Most of the sheep seen were only fair in type, and rather low in condition.

14. Although pigs are steadily and regularly becoming popular, little effort appears to have been made to modernise the type.

15. Poultry keeping is an important agricultural activity in Uruguay.

16. Crops are not very important in Uruguay, from an export point of view, but sufficient of most kinds is grown to satisfy local requirements.

17. Wheat, maize, and linseed are easily the most important crops of the country.

18. Citrus fruits develop well in Uruguay, and, as so much of the country is suited to the production of these fruits, it appears as though they will become a very important agricultural production in the near future.

19. The growing of grapes for wine-making is already an important agricultural activity, and, in all probability, will be increased to a considerable extent in the future.

20. Uruguay has possibiities of becoming an important agricultural country, relative to her size, but before this is possible, modernisation of practices is necessary.

SOUTHERN BRAZIL.

Located at about the Tropic of Capricorn and south of this line, and having a high proportion of Germans and Italians, and their descendants, amongst the population, it is reasonable to expect that it would be in Southern Brazil that the great bulk of the temperate-climate crops, and European livestock raised in Brazil would be produced. This proves to be so, and most of the meat, wool, cereals, beans, grapes and temperate-climate fruits are obtained in this zone.

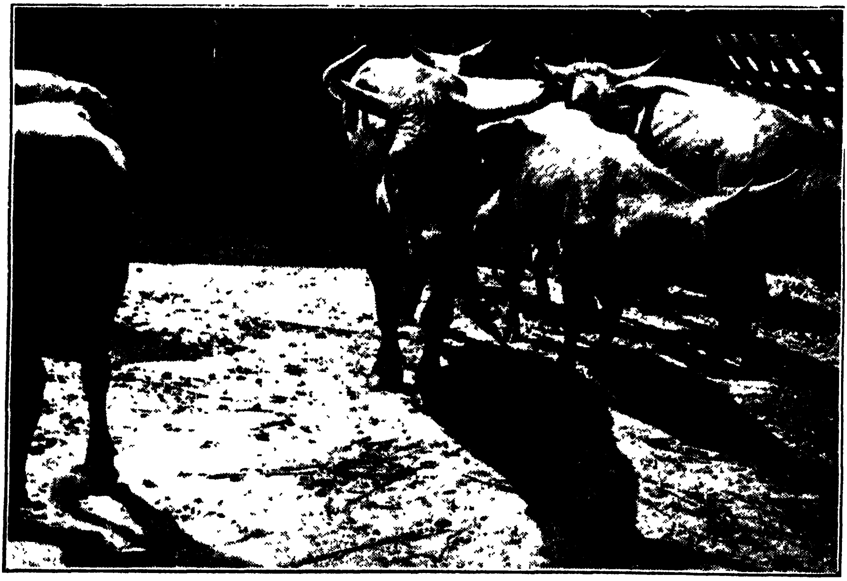
THE STATES FORMING SOUTHERN BRAZIL.

The principal part of Southern Brazil consists of the four States of Rio Grande do Sul, Santa Catharina, Paraná, and Sao Paulo, of which Rio Grande do Sul is the most southerly, and so the most temperate, in so far as climate is concerned.

The State of Rio Grande do Sul contains something over 90,000 square miles of country and, as such, is larger than the adjoining Republic of Uruguay. The average annual rainfall for the State during the 22-year period, 1910 to 1931, was 50.4in., but the variation from year to year is great, for, in 1914, the rainfall was 70.1in., whereas in 1917 it was only 26.0in. Nearly half the cattle of Brazil are maintained in Rio Grande do Sul, most of the sheep of the country are in this State, and a lot of the pigs also; and because of the rich arable soils, which exist as well as the good pastures, the production from crops such as cereals, beans, grapes (for wine and table use), and oranges is fairly high.

Fat, Hairless Pigs, Common in Southern Brazil.

Brazil maintains about 22,000,000 pigs, most of which are located in the Southern Provinces Pig fat is so important to the populace for cooking purposes that every effort is made to get the animals to put on as much fat as possible before sending them to be slaughtered. Carcasses are to be seen with 6 inches of back fat, and the pigs would be more valuable still if more fat could be developed.



Criolla, or Native Cattle of the Tropics of South America.

The direct descendants of the original cattle brought into the country by the Portuguese and Spaniards in the early days of settlement, the Criolla cattle are resistant to cattle tick and tropical diseases. These animals are used largely for Xarque and canning, and having extra thick hides are particuarly valuable for this reason.

The State of Santa Catharina, adjoining the northern boundary of Rio Grande do Sul, only contains about 16,800 square miles of territory, and because of its location is rather warmer, and although producing some of the same agricultural products, cattle comprise the principal form of livestock, and of crops coffee is of some importance.

The State of Paraná, containing about 97,500 square miles, is largely mountainous, but the other portions, which have favourable climate for crop growing, are being brought under cultivation, and the important crops are coffee, cereals, and beans.

The State of Sao Paulo is of considerable dimensions, and embraces about 112,570 square miles, and although some of the country is inside the Tropic of Capricorn, much of the State has a more or less temperate climate, and so large numbers of cattle are maintained, and a fair amount of the cereals is grown. Coffee, cotton, and sub-tropical fruits are produced in great quantities in the State of Sao Paulo, and considerable extensions have been made, and great interest is being shown, in the growing and packing for export, of citrus fruit.

LIVESTOCK IN SOUTHERN BRAZIL.

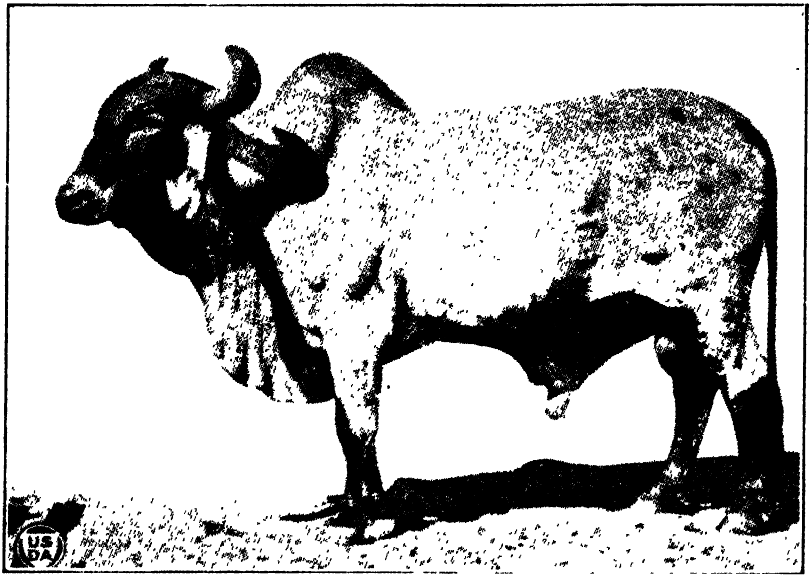
Brazil maintains about 43,000,000 head of cattle, about 11,000,000 sheep, and about 22,000,000 pigs, and most of these are to be found in Southern Brazil, the numbers of all kinds becoming greater and greater as the extreme south of the country is reached. Nearly all of the sheep and about half of the cattle are located in Rio Grande do Sul, whilst about three-quarters of the pigs are between the northern boundary of Sao Paulo and the southern boundary of Rio Grande do Sul.

A Mob of Grade Zebu Cattle at a Frigorifico in Sao Paulo.

Although of peculiar appearance to anyone accustomed to European types of cattle, grade Zebus are useful beef beasts, and produce hindquarters good enough to ship to Europe.

The cattle being handled by the frigorificos and other killing works in the south, are almost wholly of British breeds, with just a light sprinkling of crossbreds containing a little Zebu blood, but at the frigorificos located in the towns of Sao Paulo and Santos, as well as in the numerous slaughtering establishments scattered about the country in the State of Sao Paulo, Zebu blood predominates, and the only other animals of other breeds seen in any numbers are Criolla and Caracú.

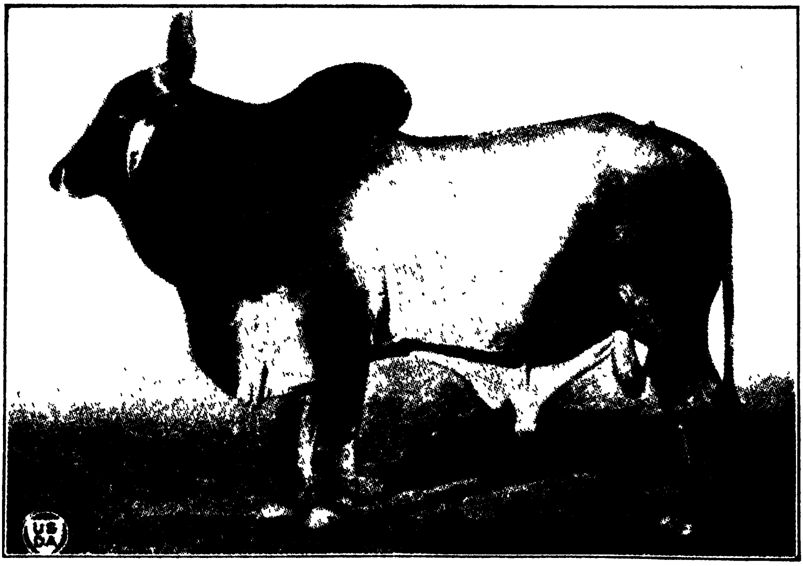
In those districts where the better breeds of cattle can be maintained, even if much attention must be bestowed upon them, it is generally recognised that the



[*From* "*Brahman* (*Zebu*) *Cattle*" (U.S. Dept. of Agric.).

Pure-bred Gir Bull.

The Gir Strain of Zebu cattle is very prominent in Southern Brazil, and although it has a marked effect in grading up native cattle, bulls resulting from mating this strain with Guzerat are of greater value for this purpose. The animals of the Gir strain are usually brindled or dull-brownish colour, and when used for grading up other breeds brindled offspring often appear.



[*From* "*Brahman* (*Zebu*) *Cattle.*" (U.S. Dept. of Agric.).

Pure-bred Guzerat Bull.

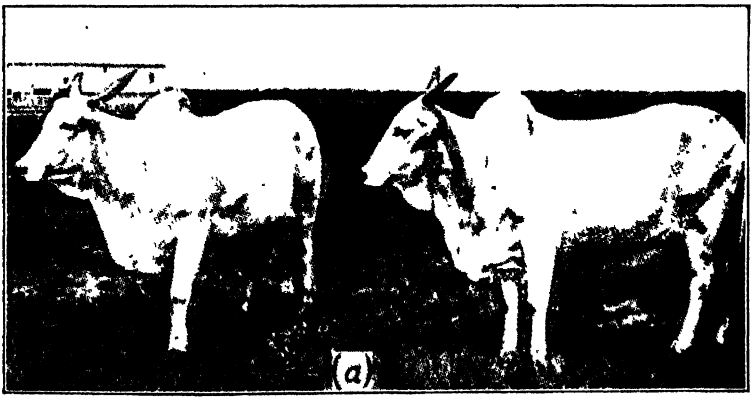
The Guzerat strain of Zebu prove adaptable to South American conditions, but are not so useful in grading up native cattle as are bulls produced when Guzerats are mated to other strains of Zebu.

Zebu can be replaced with advantage. Cattle men in the extreme south of Brazil consider that crossbred Zebu cattle are useful for rough country, and particularly if it is badly tick-infested, but should be eliminated as soon as the country is cleaned up, and then Herefords should be used, even though it is necessary to dip them every 18 days in the bad season, and less frequently at other times.

[*From "Brahman (Zebu) Cattle."* (U.S. Dept. of Agric.).

A Zebu Bull, the Progeny of the Mating of Gir and Guzerat Strains.

This kind of Zebu bull grades up the native cattle of Southern Brazil much better than do the bulls of either of the strains from which it is derived. The mixing of the strains gives greater development to the individuals produced, and also appears to increase their vigour and prepotency.



[From *Kelley's "Zebu Cross Cattle."*

Pure-bred Nellore Cows.

Animals of the Nellore strain of Zebu cattle are also used in Southern Brazil, but not to the same extent as Gir and Guzerat strains.

Although Zebu cattle are not held in great favour where the climate is sufficiently temperate in character to admit of the production of better-class cattle, they are very popular indeed in the warmer districts of Southern Brazil, and many cattle men foresee the day when other breeds will be replaced entirely by Zebus or Zebu crossbreds. Even though very little care has been shown in the selection of the breeding animals, they are gaining in popularity day by day, and an important trade in the exportation of hindquarters of Zebu cattle has already been developed. The meat of Zebu cattle is of a lighter colour than that of the British breeds, and as such is much more attractive when chilled, but, on the other hand, because of this light colour, canners prefer the darker-coloured meat of the British breeds.

A strong effort is being made by the meat exporters of the State of Sao Paulo to improve the Zebu cattle of the country, and good-quality bulls are being imported for the purpose, and stud herds have been established. It is being found in these cattle-improving tests that bulls of the various strains of Zebu brought direct from India do not lead to a very marked improvement of the local animals, but that animals bred in Brazil are very much better in this regard, and particularly is this so if the bulls bred in the country are the result of crossing two strains of Zebu together. The most of the importations are of the Gir and Guzerat strains of Zebu, and when animals of these two strains are mated together they produce specially good bulls for grading up the native cattle. The other important strain being used is the Nellore, but less is heard of this strain than of the other two.

Zebu cattle are very quiet indeed when carefully handled, but are inclined to take fright easily, and then are difficult to manage. When disturbed they have the reputation of being faster than horses, and are able to leap all ordinary fences with the greatest of ease, and bulls and steers are said to charge almost anything on sight.

There is a Herd Book kept in the city of Sao Paulo for Caracú cattle, and large numbers of animals of this breed are produced in the State, and pure-bred bulls are in fair demand at remunerative prices. The Caracú breed is derived from the early importations of Portuguese cattle, but beef exporters claim that besides not being as hardy as the Zebu, they do not kill out so well, and as a consequence these men are encouraging cattle breeders to increase the numbers of Zebu at the expense of the Caracú.

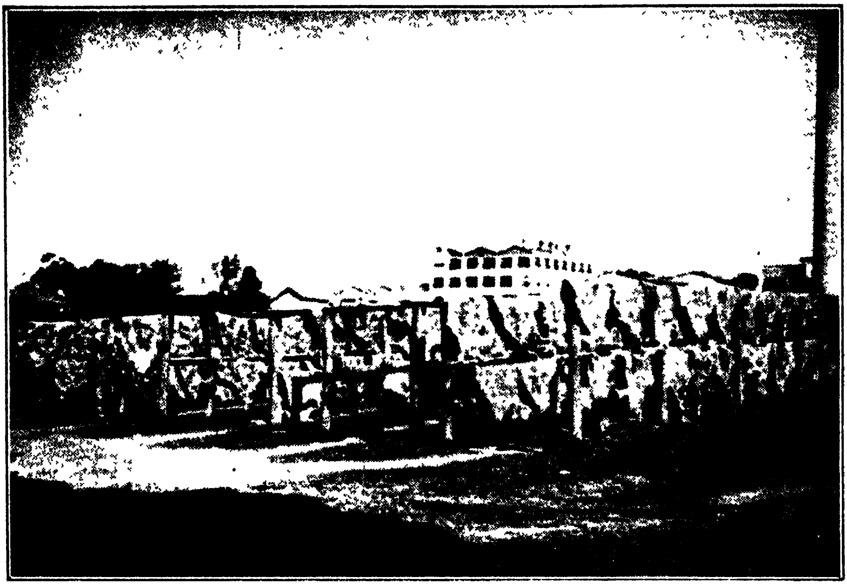
THE PRESERVATION OF BEEF AS XARQUE.

Before the advent of freezing for the preservation of meat, or the sealing of meat in cans or other containers, enormous quantities of beef were preserved in South America with the aid of salt and sundrying. This material, known as Xarque, is still of such importance that the meat from over 1,000,000 head of cattle is preserved in this manner each year in Southern Brazil. As a rule, rough cattle are used for Xarque, but for this method of preservation the meat from such animals is quite as good as from the best of cattle. The flesh of the carcasses, including the fat, is removed in slabs about 5ft. in length by 2ft. 6in. in width, and has the animal heat removed by being subjected to a strong blast of cooled air from powerful fans. With sharp knives, the meat is slashed in long lines a few inches apart, the cuts being nearly deep enough to go right through the slabs of meat. The slabs are thrown into a tank of strong brine, and kept there for 45 minutes, being agitated with plungers worked by hand for the whole time. On removal from the tank the slabs are stacked to a height of about 5 feet, a full covering of coarse-salt being given to each layer of meat. The meat is restacked after 24 hours in the first stack, this time without a further addition of salt, and is kept in the stack for another 24 hours, when the surplus salt is removed from the meat. Depending upon the weather at the time, the meat is carted out for sun-drying, or is again re-stacked, where it can remain with perfect safety for 4 months or so. When sun-drying starts, the slabs are put out on trellis-like fences every morning, and brought into stacks every evening, and covered with tarpaulins for the nights. On the completion of drying the slabs are packed in bales, putting 500lbs. per bale. This unattractive dried meat is sold in Brazil, and is used in soups, and as flavouring for the staple foodstuff of so many people, viz., beans.

[From *La Industria de las Carnes en el Uruguay.*

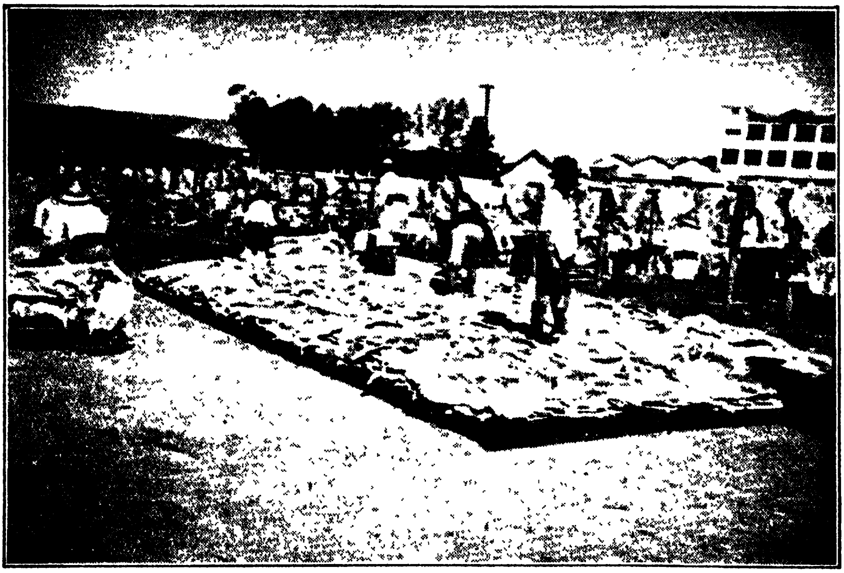
A Slab of Xarque, as made in South America.

For preservation as Xarque the whole side of the carcass of beef, except the hindquarters, but including all the fat as well as the lean, is kept intact, and after salting and sundrying has the unattractive appearance as here shown.



Sundrying the Beef in the Preparation of Xarque.

After being immersed in brine for a short time, and then drained and stacked with a liberal allowance of coarse salt, the slabs of meat are hung on fences to dry in the sun.



Stacking the Slabs of Beef which are being Converted into Xarque.

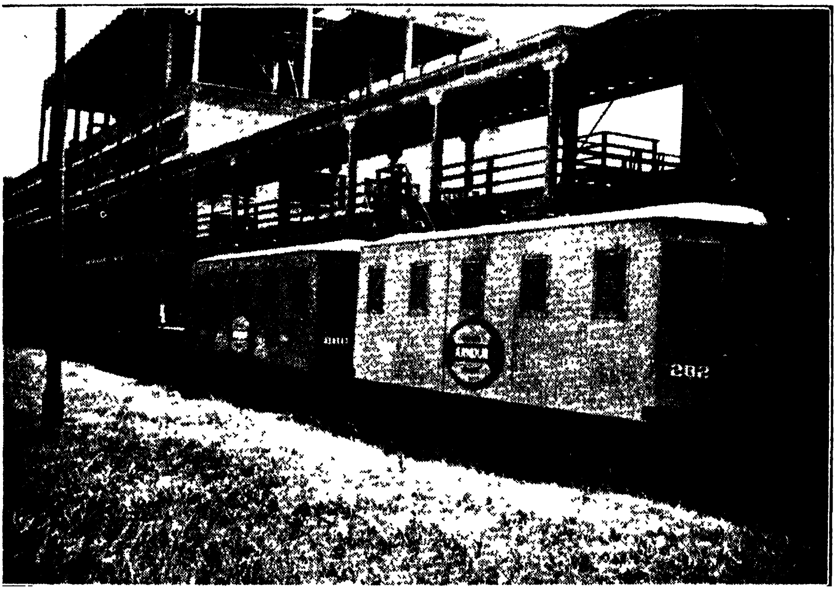
In the manufacture of Xarque the partly dried meat is brought on to wooden platforms every evening, carefully stacked, and covered with tarpaulins to protect it from rain and dew.

DISTRIBUTION OF MEAT IN SAO PAULO.

The large city of Sao Paulo, with a population of over 1,000,000 souls, has simplified the distribution of the meat to the people by utilising the electric tram system of the city. Armour's Frigorifico, of Sao Paulo, does much of the slaughtering for the city, and cool vans, run by the Electric Tram Company on the tram lines, pull right alongside the killing works, load up with carcasses, and deliver them to depots in various parts of the city, from where the retailers pick up their supplies.

ORANGES IN SOUTHERN BRAZIL.

Of considerable interest to Australia is the fact that the number of oranges being exported from Brazil is on the increase. In the past great quantities of oranges have been handled more like potatoes than as valuable fruits, and loose heaps were to be seen on barges on the rivers, and on railway trucks, but of recent years modern packing sheds, with up-to-date grading and cleaning equipment, have been installed, and large quantities of good quality fruit, properly prepared for market, are being shipped in cool chambers to Europe. The oranges being exported are of a different type to those being handled in Australia, but come into direct competition with fruits from South Africa, being of a large size, with only fairly fine-textured skin, and of a colour varying from almost green to a light yellow. The Brazilian oranges are really juicy and quite sweet, and although the early ones are not of very attractive appearance, they are very good fruit because of flavour and juiciness.



Cool Vans for Meat Used on the Lines of the Electric Tram Company in Sao Paulo, Brazil, at the Frigorifico to Collect Loads of Meat.

Meat is loaded on the vans at the slaughtering works and delivered to depots in the city.

Oranges are grown so easily in much of Southern Brazil, water is plentiful for helping their growth, modern methods are being utilised in exporting the fruit the European market is relatively close, and they are so readily saleable in Europe, that a very considerable extension of orange-growing can be anticipated in the near future.

SUMMARY OF IMPRESSIONS GAINED IN SOUTHERN BRAZIL.

1. Southern Brazil, consisting of the States of Rio Grande do Sul, Santa Catharina, Paranà and Sao Paulo, covers about 316,870 square miles of territory.

2. The rainfall of the southern end is about 50in. on the average, but varies between very wide limits from year to year.

3. Brazil maintains about 43,000,000 cattle, about 11,000,000 sheep, and about 22,000,000 pigs, and most of these are to be found in Southern Brazil.

4. Most of the cattle slaughtered in the south of Southern Brazil are of British breeds, whereas most of those killed in Sao Paulo are of Zebu blood.

5. Most cattlemen are convinced that where the British breeds of cattle can be maintained, they should be, even if a lot of attention to them is necessary, but in rougher country, where the cattle tick is very bad, and other tropical diseases prevalent, the Zebu has no competitor.

6. Despite the improvements brought about for the preservation of meat, Xarque is still so useful in Brazil that the meat of over 1,000,000 cattle is preserved in this way annually.

7. The city of Sao Paulo, with a population of over 1,000,000 people, distributes her meat for local consumption on the electric tram lines of the city.

8. Oranges are becoming an important export line of Brazil, and they are grown so easily that a considerable extension in the industry in the near future seems inevitable.

CONCLUSIONS FORMED DURING TOUR.

The conclusions to be drawn from the investigations made during the tour of portions of the Southern Hemisphere with temperate and sub-tropical climate, are:—

1. Besides being a beautiful country, New Zealand is a remarkably good agricultural country, particularly as regards the production of dairy produce and sheep for meat.

2. In all probability the best pastures in the world are to be found in New Zealand, the natural conditions encouraging the full growth of pasture plants, and the farmers being extremely efficient managers of pasture lands.

3. The seed certification scheme, as inaugurated in New Zealand, and developed and controlled by the Department of Agriculture, is playing a great part in the improvement of New Zealand pastures.

4. The Meat Producers' Board of New Zealand has been functioning for 13 years, and so successful have its efforts been that it is the envy of most meat-exporting countries. Producers are adequately represented on this Board, for 5 of the 8 members are direct representatives of meat producers.

5. Co-operation is very important in the dairying industry of New Zealand, and it appears that much of the success attained in this branch of agriculture is due to this fact.

6. We have so much to learn from New Zealand in connection with pastures, dairying, fat lambs, and co-operation that officers of the Department of Agriculture should be sent more frequently than in the past to that country, to get first-hand knowledge of the progress being made.

7. Chile is a direct competitor with Australia with wines and barley, and although the agriculture is rather backward in some directions, has great potentialities for the production of all Mediterranean-climate crops. It appears however, that the development of her agricultural resources cannot be brought about quickly, and further she is handicapped in a similar manner to Australia in the time taken to place primary products on the European markets.

8. Argentina is such a wonderful agricultural country that she could, if allowed, swamp the markets of the world in which Australia is interested, with all the agricultural products which are produced in the temperate and sub-tropical portions of the Southern Hemisphere, except Merino wool.

9. The greatest competitor of Australia at the moment, Argentina is likely to become still greater as time goes on.

10. To be able to contend with the competition of Argentina, Australia is dependent upon the political advantage she has in being one of the units of the British Empire.

11. It will be necessary to extend the political advantage of Australia to enable her to meet the increasing competition from Argentina, and this can probably be done best by forming a close association with other outlying parts of the Empire, and more particularly those in the Southern Hemisphere, of which the most important are New Zealand and South Africa.

12. To encourage Great Britain still further to purchase Empire products in preference to foreign, an effort should be made to balance the trade to and from that country. Other things being at all equal preference should be given to the purchase of goods from the United Kingdom.

13. Although Uruguay maintains a fair number of sheep, and is an exporter of wool and sheep meat, it does not appear as though this country can ever develop into an important competitor of Australia with any agricultural product.

14. Southern Brazil exports a lot of oranges to Europe, and is constantly increasing supplies, but being of the type produced in sub-tropical climate, they do not compete directly with Australian export oranges.

15. Zebu cattle, and their crossbreds, are giving complete satisfaction in the tropical parts of Southern Brazil, and will probably do the same for the portions of Australia with similar climatic conditions.

16. Throughout South America livestock for slaughter are sold by live weight, a method which ensures that the producer gets paid for what he produces, and at the same time simplifies things for the buyer.

17. South Africa is a direct and important competitor with Australia with Merino wool, and it appears that her wool industry would be improved by the lifting of the embargo on the exportation of stud Merino sheep from Australia.

18. Everything possible should be done towards retaining the most friendly relationships with South Africa, for it appears that it will take the combined efforts of New Zealand, South Africa, Australia, and other parts of the Empire located in the Southern Hemisphere, to compete successfully with South America.

19. Arising from the tour of portions of the Southern Hemisphere is one conclusion which overshadows all others, and that is, that the competition now being faced by Australia from South American products will get greater and greater in the near future, and that the sooner steps are taken to combat it, the better. In this connection the following suggestions are made:—

(*a*) A serious endeavour should be made to balance the trade between the United Kingdom and Australia by purchasing goods made in Great Britain whenever possible.

(*b*) A close trade association between the parts of the Empire located in the Southern Hemisphere should be developed as soon as possible.

(*c*) To educate agriculturists in the needs, aims, production, and practices of the various parts of the Empire, an Empire Agricultural Convention should be organised to meet every year, or at least every second year, in one or other of the Empire countries.

(*d*) Australia, being dependent upon its agriculture, and the progress of agriculture being dependent upon selling overseas, every effort should be made to produce and prepare articles of a quality to retain any market once gained. This can be done by very rigid inspection to high standards of quality at ports of embarkation, and helped by attaching to all Departments of Agriculture a commercial branch to advise agriculturists on market requirements, current prices, co-operation, &c.

(*e*) To help counteract the wonderful natural advantages of South America, the cost of production of agricultural produce must be lowered, which can only be done by increasing the yield per unit. To do this agriculturists must be kept abreast of the times, and so a fully-staffed, efficient Department of Agriculture, including officers for field crops, horticulture, viticulture, veterinary science, cattle, sheep, pigs, wool, poultry, bees, irrigation, and marketing, must be maintained at all times.

(*f*) In South Australia, where manufacturing advantages are not great, the development by the people, of an agricultural outlook, would help maintain an export balance.

(*Concluded.*)

THE APPLE THRIPS (*THRIPS IMAGINIS* BAGNALL) IN SOUTH AUSTRALIA.

[By J. DAVIDSON, D.Sc., Waite Agricultural Research Institute, University of Adelaide.]

I. INTRODUCTION.

A widespread plague of the apple thrips occurred throughout the southern States of Australia during the spring of 1931. The insects infested apple blossom in large numbers during October; with mid-season and late varieties of apples there was consequently a poor setting of fruit. Bush and berry fruits, also garden flowers, suffered considerable damage.

There are no definite records of earlier plagues of thrips in this State; but there is little doubt that previous infestations have occurred, since outbreaks have been recorded in other States at intervals during the past 30 years.

Owing to the heavy losses in the apple growing industry, attributed to the thrips plague of 1931, an investigation of the thrips problem was undertaken as a co-operative enterprise between the Commonwealth Council for Scientific and Industrial Research, the Waite Research Institute of the University of Adelaide, the Thrips Investigation League and certain of the State Departments of Agriculture. The headquarters of the investigation were placed at the Waite Institute. An account of the research programme and details of the personnel of the investigation are given in the *Journal* C.S.I.R. (1933), p. 216. Articles dealing with various aspects of the work, written by members of the Thrips Research team, have appeared from time to time in that journal. The first annual report was published in the "Fruit World of Australasia," 1st October, 1933; the second annual report appeared in the same journal, 1st December, 1934. The present article reviews the position regarding the apple thrips problem in South Australia; it is based on information which has been established by members of the Thrips Research team, during the progress of the investigation.

We are indebted to the Horticultural Branch of the Department of Agriculture of South Australia for assistance in matters relating to orchard experiments and general field observations. Through the courtesy of Mr. G. Quinn and Mr. A. G. Strickland facilities were afforded us at the Government Orchard, Blackwood, where we received much help from the manager, Mr. R. Fowler.

Several orchardists offered facilities for experiments to be carried out on their properties; others co-operated by sending in samples of blossom infested with thrips for purposes of keeping records. In particular we owe a great deal to Mr. H. N. Wicks, of Balhannah, for the helpful assistance he has given us in all matters relating to our investigations. Mr. Wicks has maintained a close association throughout the progress of the work, and his experience and advice on practical matters, have been invaluable.

Finally, our warm thanks are due to Mr. E. Leishman, district horticultural officer, for his friendly co-operation and active assistance throughout the whole period that the investigation has been in progress.

II. DESCRIPTION AND LIFE HISTORY.

The apple thrips is a flower inhabiting species, apparently indigenous to Australia. It was first described by R. S. Bagnall in 1926 from specimens collected round Adelaide and Melbourne.

Several species of thrips inhabit blossom and flowers in association with *T. imaginis*; in particular, the common "onion thrips" (*Thrips tabaci*) closely resembles the apple thrips, and prior to 1926 the latter species was recorded as *T. tabaci*. During early spring, the "eucalyptus thrips" (*Isoneurothrips australis* Bagnall) commonly occurs in pear and stone fruit blossom.*

All thrips have a rather narrow, elongate body and relatively short antennae consisting of 6 to 9 segments. The adults (with the exception of certain species) have narrow wings, which extend to about the length of the body and bear a row of long setae along their margins; these setae give a fringe-like appearance to the wings, hence the name given to this group of insects, *Thysanoptera* (*thusanos*, a fringe; *pteron*, a wing). The immature stages of thrips are wingless.

The adult female of *T. imaginis* averages 1/20in. long and 1/100in. wide across the thorax; a stout, chitinous ovipositor is situated in the posterior end of the abdomen. The body, over the anterior portion, is golden-brown with a reddish tinge; the posterior area is brownish-yellow to a darker brown; individuals which have newly emerged from pupae are yellowish in colour, but gradually darken. The adult male is smaller than the female and lighter in colour, with a paler yellowish abdomen.

The immature stages consist of a first and second stage nymph, and a prepupa and pupal stage. These stages are illustrated in Fig. 1.

The essential features by means of which the apple thrips can be distinguished from its associate, the onion thrips, can be recognised with the aid of a hand lens. With *T. imaginis* a number of small, fine setae are found irregularly scattered over the ventral surface of the abdominal segments; with *T. tabaci* there is present in these situations only a single row of somewhat larger setae. With *T. imaginis* the ocellar crescents are red; with *T. tabaci* they are yellowish to brownish. The nymphs of *T. imaginis* are generally orange-yellow in colour whereas those of *T. tabaci* are lemon-yellow in colour.

---

*An account of the common economic species of thrips found in Australia which includes species associated with *T. imaginis* is given by H. V. Steele (Pamphlet 54, C.S.I.R. (1935)).

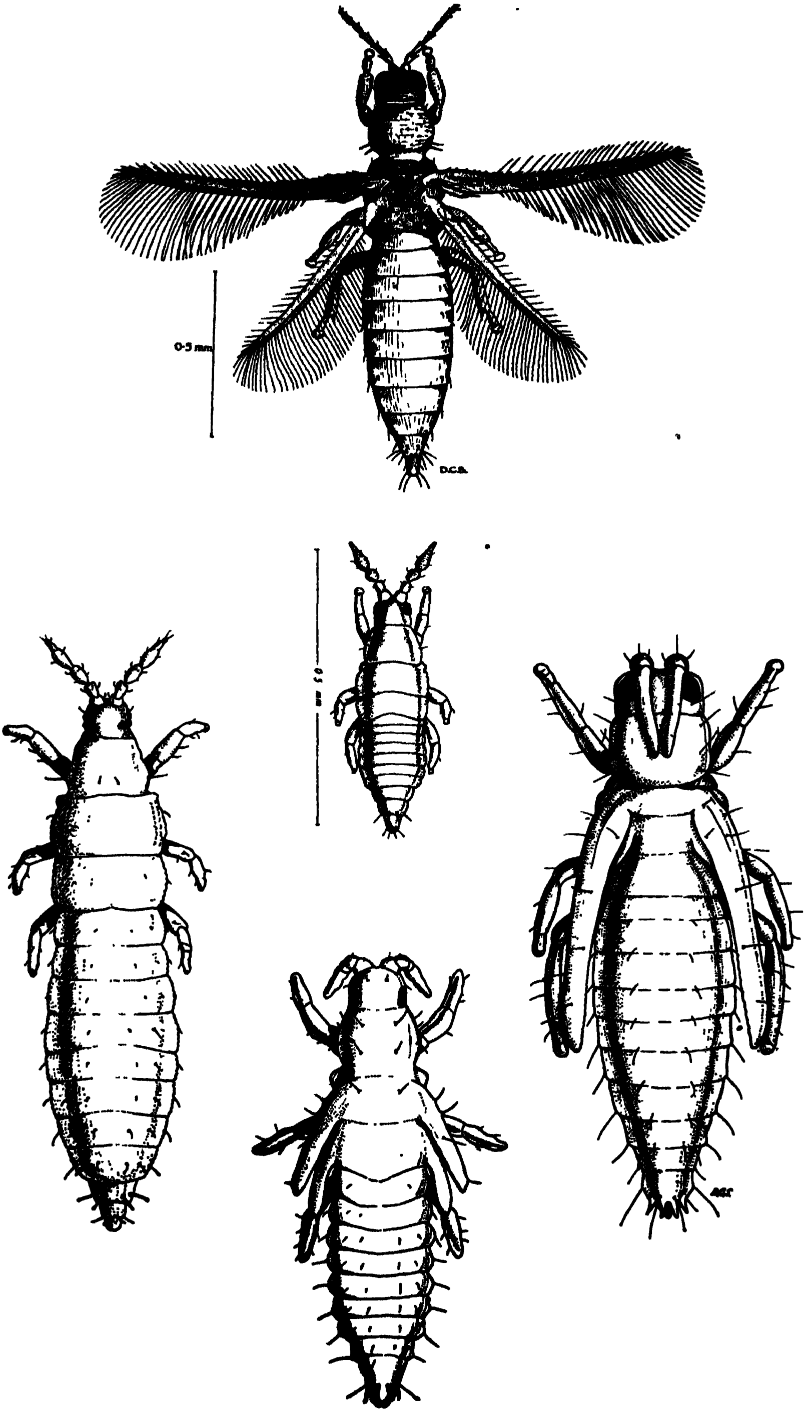


Fig. 1.

Showing all stages of *Thrips imaginis* Bagnall; first and second stage nymphs, pre pupa (male), pupa (female), adult female.

The life history of *T. imaginis* is simple. The female pierces the tissues of the flower with its ovipositor and deposits its oval, transparent eggs in the tissues; the eggs are laid in all parts of the flower, including the stamens and pistil. The newly hatched nymph (*first stage nymph*) is whitish, but soon becomes yellowish in colour; it feeds on the tissues of the flower destroying the epidermal cells with its piercing mouth parts and sucking out the juices from the cells. The *first stage nymph* moults and becomes the *second stage nymph* which is orange-yellow in colour. When the second stage nymph is mature, it leaves the plant and passes into the soil where it develops into the *prepupal stage*; this stage has short wing buds and can move about in the soil, but does not feed. The final stage or ***pupa*** has well developed wing buds; it remains more or less quiescent in the soil until the emergence of the adult.

Although two quasi-resting or pupal stages occur in *T. imaginis*, the degree of metamorphosis is ill-defined. Some authors refer to the first stage nymph as the "larva." The character of the metamorphosis resembles that found in the Heteroptera and it appears to be more appropriate to speak of the early stages as nymphs.

III. FOOD PLANTS AND HABITS.

The apple thrips inhabits the flowers of a wide range of plants. In spring it is common in fruit blossom, vines, grasses and garden flowers. Cape weed (*Cryptostemma calendulaceum*) and Salvation Jane (*Echium plantagineum*), which often flower over large areas in spring, may be heavily infested.

The insects feed on the delicate tissues of the flower; they lacerate the epidermal cells with their piercing mouth parts and suck out the contents of the damaged cells. The mouth parts are illustrated in Fig. 2. The head is prolonged into a mouth cone through which the piercing stylets are forced into the tissues. The stylets represent the paired mandibles and maxillae of other insects, but only one mandibular stylet is present; this stylet is considerably larger than the maxillary stylets.

During feeding, the stout mandibular stylet is forced into the epidermis, the cells being lacerated by the combined action of the three stylets. This causes a local accumulation of juices from the damaged cells. The mouth cone, which bears a number of sensory bristles, is now adpressed to the lacerated tissue and the juices are sucked up into the pharynx, from which they are passed along the oesophagus to the stomach. A secretion from the salivary glands passes along the salivary ducts into the chamber of the salivary pump; while the insect is feeding, the secretion is pumped from this chamber along the salivary canal to the wound in the plant tissues; when mixed with the plant juices it assists in the digestion of the latter.

Where the insects are feeding in blossom or flowers, the stamens, pistil, and petals may become dry and brown owing to oxidation reactions in the damaged cells, and loss of juices from the delicate tissues. The damage is greater during hot, dry weather, particularly with hot, north winds. Under these conditions extensive "browning" of flowers and blossom may occur and in some instances as with apple blossom they may fail to set fruit, owing to the destruction of the stamens and pistil.

In normal years only a few individuals will be found in apple blossom; during an infestation year, as in 1931, 150 individuals may be present in each blossom. The insects may occur in stone fruit blossom, pear and early flowering apple varieties if the spring is favourable for a thrips infestation. Normally early flowering apple varieties such as Cleopatra and Gravenstein have completed flowering before thrips are numerous; the mid-season varieties such as Granny Smith and Jonathan are more liable to infestation; the late varieties such as Rome Beauty and Buncombe invariably suffer damage in an infestation year. Bush and berry fruits, garden flowers and vines may suffer heavy infestation in November and December.

IV. FLUCTUATIONS IN NUMBERS THROUGHOUT THE YEAR.

T. imaginis may be found in flowers throughout the year in the Adelaide district, but the numbers fluctuate according to the favourableness of the period of the year. During the past four years daily counts have been made at the Waite Institute of the number of adult thrips present in roses. Graphs illustrating the numbers of *T. imaginis* are given in Fig. 3. The points on the curves represent the average number of individuals in one rose for 10 day periods.

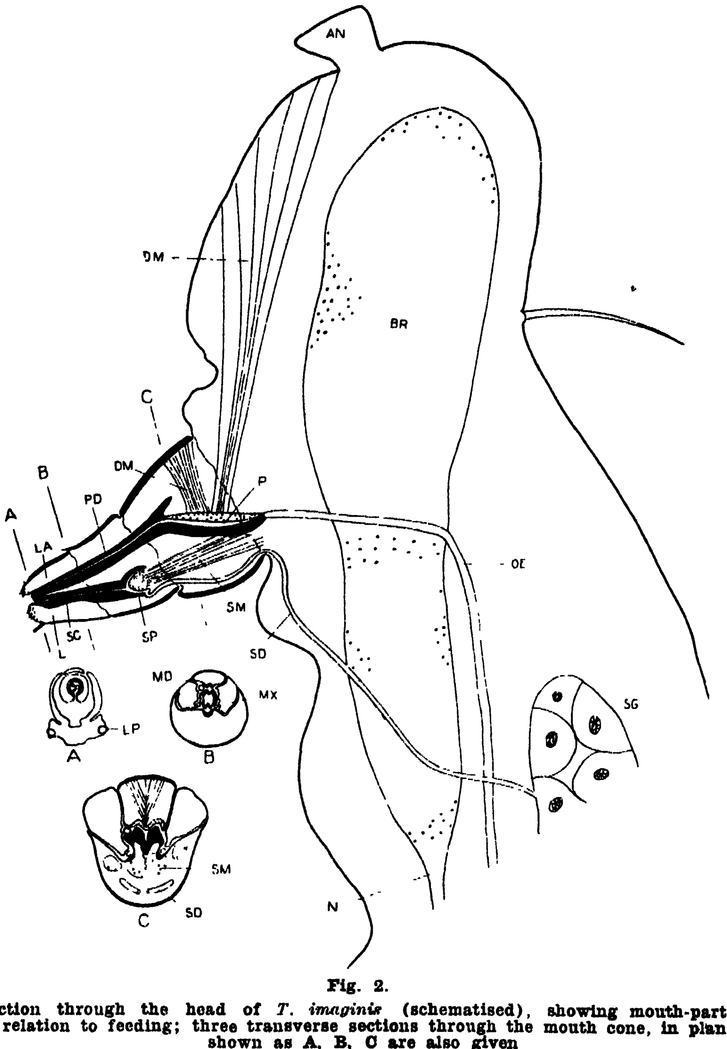

Fig. 2.

Section through the head of *T. imaginis* (schematised), showing mouth-parts in relation to feeding; three transverse sections through the mouth cone, in plane shown as A, B, C are also given

A. Section near tip of mouth cone; note stylets in section.

B Section through mouth cone, showing pharyngeal canal and salivary canal and portions of sclerites of the head; the maxillary stylets (MX) and mandible (MD).

C. Section through mouth cone immediately behind the salivary pump, showing pharynx.

BR, supra aesophageal ganglion or brain; DM, divaricator muscles of the pharynx; LP, labial palp; LA, labrum; L, labium; N, nerve; SG, salivary ganglion; OE, oesophagus; PD. pharyngeal canal; SC, salivary canal in hypopharynx; SP, salivary pump; SM, pump muscle; SD, salivary duct.

Commencing with the mid-summer period, thrips occur in small numbers during the hot, dry, summer months. This is associated with dryness of the soil, which is unfavourable for the pupal stages and causes heavy mortality; dryness also results in less flowers being available, compared with the spring period.

The number of thrips increases in the autumn, which is referred to as "the autumn rise." The extent of this increase is dependent upon the favourableness of the autumn weather, particularly rainfall which results in suitable soil moisture and growth of plants.

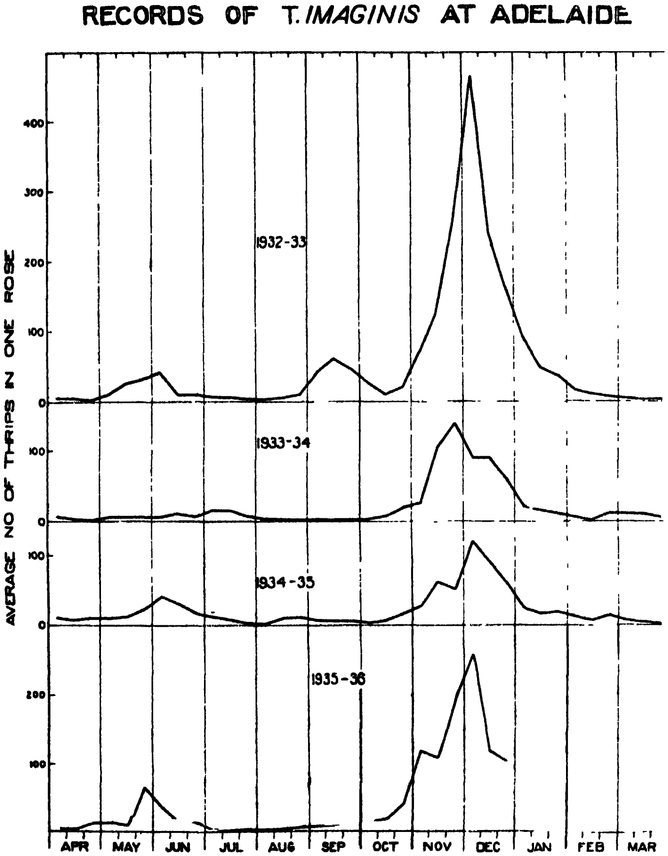

Fig. 3.

Showing fluctuations in the numbers of *T. imaginis* in the Adelaide district The points on the curves represent average number of individuals in one rose at ten-day intervals

As autumn advances into winter, the number of thrips decreases. This is due to low temperatures which retard development and restrict the activity of the adults. The insects pass the winter as pupae in the soil or as dormant adults in sheltered situations; some active individuals may be found in flowers, especially on warm sunny days.

With the advent of warm spring days, there is a marked increase in the number of active thrips. This is due to the emergence of adults from overwintering pupae and to renewed activity of dormant adults. The early spring rise in numbers is referred to as "the first spring rise"; it may occur early or late according to the favourableness of the prevailing weather, particularly temperature. The extent of the first spring rise depends upon the extent of the previous autumn rise, survival during the winter and the character of the prevailing spring weather.

The first spring rise is followed by a further increase in numbers, which is referred to as the "second spring rise." This rise is due to the development of a further generation of individuals following on the first spring rise. The date of its occurrence and extent depends upon the date and extent of the first spring rise and the favourableness of the spring weather. With the advance of the dry summer months the numbers of thrips decrease.

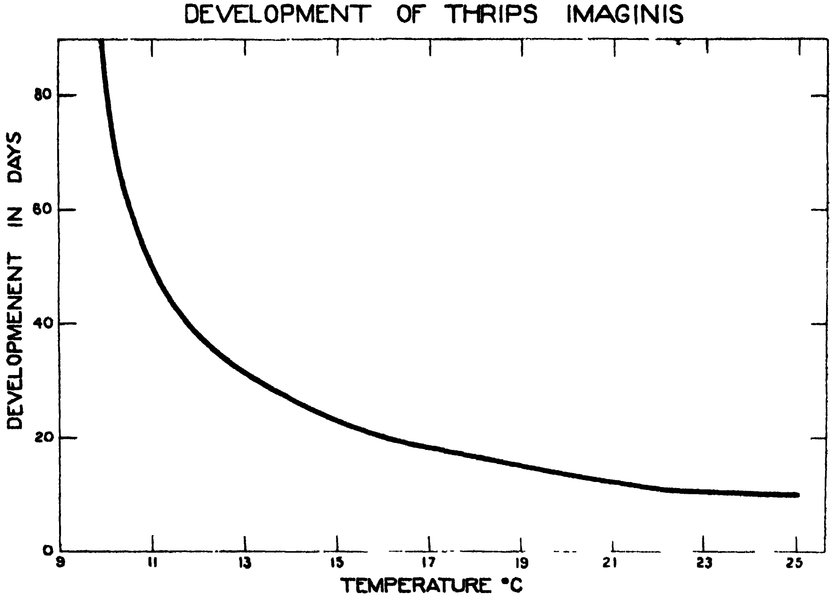

Fig. 4.

Curve showing approximate period required for the complete development of *T. imaginis* according to temperature during the period.

It is seen from Fig. 3 that the general trend of the fluctuations in the numbers of *T. imaginis* is the same every year, but the actual numbers present during the spring period varies from year to year. This is due to changes in the weather. In those years in which the weather favours a large increase in the numbers of thrips as a second spring rise, early in October, heavy infestation of apple blossom may be expected. With the development of a further generation of the insects during November or December, bush and berry fruits, garden flowers and vines may be heavily infested.

The following features of the biology of *T. imaginis* which have been established by experimental work during our investigations, illustrate the manner in which weather factors, such as rainfall and temperature influence the rate of multiplication of this insect.

When food and moisture are favourable, temperature is the major factor affecting the activity and development of *T. imaginis*. The insects are sluggish at temperatures below 10° C. (50° F.); they are very active when temperatures are about 21° C. (70° F.) and over, particularly when the weather is hot and dry.

The rate of development of *T. imaginis* in relation to temperature has been calculated from the results obtained with the development of 249 eggs at six different constant temperatures, and the development of 151 individuals reared from hatching to adult at five different constant temperatures. The theoretical temperature value at which development ceases (developmental zero) was found to be 9.3° C. (48.8° F.) for the embryo and 7.02° C. (44.6° F.) for the post-embryonic stages. By using the formula $D(T—C) = K$, where D = development in days, T = temperature and C = developmental zero, the value for K is 41.3° C. (74.3° F.) for embryonic development and 125-5° C. (225.9° F.) for post-embryonic development. The formula gives a good approximation to the developmental period at temperatures between 10° C. (50° F.) and 25° C. (77° F.).

A combined curve (Fig. 4) based on the above data, may be used for all practical purposes of determining the approximate period required for T. *imaginis* to pass through its life cycle at a given temperature.

The length of life of adults varies with temperature. At 8° C. (46.4° F.) females lived from 84 to 364 days; at 12.5° C. (54.6° F.) they lived on an average 138 days: at 23° C. (73.6° F.) they lived from 23 to 66 days. At the higher temperatures females appear to live longer than males; at 23° C. (73.6° F.) the average length of life of males was 31.5 days, while females lived on an average 45.7 days.

Egg laying activity is influenced by temperature. At 12.5° C. (54.6° F.) females began to lay on the 10th day after emergence from the pupa; at 16° C. (61° F.) oviposition occurred on the fifth day, at 20° C. (68° F.) on the fourth day and at 23° C. (73.6° F.) on the third day.

In a favourable environment, oviposition appears to go on steadily throughout the life of the female. The average number of eggs laid per day varied from 1.38 at 12.5° C. (54.6° F.) to 5.5 at 23° C. (73.6° F.).

The total eggs laid by a female throughout life varied from 186 at 16° C. (61° F.) to 251 at 23° C. (73.6° F.), but the difference in the numbers of eggs at these temperatures is not significant. At 8° C. (46.4° F.) on the other hand, only 18 eggs (average) were laid; the greatest number of eggs laid by one female at this temperature was 40. Two females maintained at this temperature, lived for 308 and 357 days respectively, but did not lay any eggs.

Food appears to have an important influence on fertility. With nine females feeding on stamens of Snapdragon (*Antirrhinum*) from which the anthers had been removed, an average of 19.8 eggs was laid; with females which were feeding on stamens complete with anthers, an average of 209 eggs was laid. The explanation of these results appears to lie in the high protein content of the anthers.

Apart from temperature and food, air humidity and soil moisture influence activity of the insects and the mortality rate. The adult insects are particularly active during hot, dry weather and may move about in swarms. They feed actively during these periods and obtain the necessary moisture from the tissues of the flowers of their food-plants: The pupal stages in the soil are susceptible to dryness since they do not feed and under drought conditions mortality is heavy.

V. SUGGESTIONS FOR CONTROL MEASURES.

The important weather features which favour the occurrence of the apple thrips in economic numbers in spring are early autumn rains and a wet autumn, followed by an early and sustained warm spring. The date of the occurrence of the "first spring rise" and its extent will be an important guide to the degree of infestation which may be expected during the spring. Where conditions favour the development of large numbers of thrips as a second spring rise early in October a heavy infestation of apple blossom may be expected.

The thrips will be widely distributed over the infested area. They will move avtively on hot, dry days and infest flowers and blossom. With most varieties of apple the thrips enter the buds at the base of the petals, before the buds open; they damage the stamens and pistil; if thrips are numerous, the blossom may not set fruit. They also feed on the exposed portion of the petals, causing them to turn brown. When the buds open, the insects continue to infest the blossom.

During a heavy infestation, it is impracticable to aim only at killing the thrips infesting the blossom, since the insects are abundant over a wide area. The aim should be to drive the thrips out of the blossoms, and protect the latter during the critical periods of the invasion by the application of suitable dusts or sprays. It is important to anticipate movements of the thrips, and suitably time the application of the insecticide. It is best if the protective cover can be applied when an invasion is imminent, which will normally occur during hot days.

During the period that the Thrips Investigation has been in progress, the numbers of thrips in the spring have been too small to allow of adequate field trials being made with insecticides. By means of laboratory and restricted field tests, certain insecticides have been selected for extended field trials when the opportunity offers. Until results from adequate field trials have been obtained, a definite opinion cannot be given regarding the efficiency of the following insecticides under field conditions.

(*a*) TREATMENT OF UNOPENED BUDS.

Spraying or dusting as for open blossoms (*b*) may be used. A finely-ground substance like kaolin, applied as a wet spray, to which a spreader has been added, may form a temporary mechanical barrier over the openings into the buds, and prevent the entrance of thrips. The spray is cheap and harmless, and may be applied in heavy doses. We have had insufficient field experience with this method to enable us to make any recommendation at present. The spray is of no use applied to open blossom.

(*b*) TREATMENT OF OPEN BUDS.

The aim should be to apply an insecticide which will drive thrips out of the open blossom, and keep them out during critical hot days. Dusts are convenient for this purpose, and the formula given below has given promising results with small tests:—

	Per cent.
Kaolin or talc	80 or 70
Derris (finely-ground)	15 or 20
Pyrethrum (finely-ground)	5 or 10

Derris and pyrethrum repel thrips; they gradually lose their toxic properties on exposure to air and sunlight. In orchard practice, it is not expected that the dust will be effective for more than two days after application to the trees. Further applications will be required as necessary. Dusts having the higher concentrations of derris and pyrethrum will be more efficient, but more costly. The formula is based on ground derris root, of which about 90 per cent. passes through a 200-mesh sieve, and containing 3.5 per cent. rotenone; the pyrethrum used contained 0.2 per cent. pyrethrins. A hand rotary or knapsack duster can be used for small areas; a larger machine will be desirable for extensive areas; a suitable allowance of dust is ½lb. per tree. Where derris cannot be obtained, a pyrethrum dust may be used, but its efficiency will be considerably less than a dust containing both derris and pyrethrum.

We have had little success up to the present with experiments with sprays. It is recommended that dusts should be used wherever possible.

For growers who desire to use a spray, the following formua is suggested:—

Finely-crushed derris root	2lb.
Soap	5lb.
Water	100galls.

This spray can be made up by the grower; it must be prepared fresh, immediately before use, since it deteriorates in efficiency on standing.

Oil emulsions containing derris and pyrethrum appear to be more promising than aqueous sprays, but the work in progress on these emulsions is still in the experimental stage.

The dust formula given above may be used for bush and berry crops and for garden flowers.

Although the damage to apple blossom caused by thrips may prevent the normal set of fruit, other factors appear to be associated with the irregular setting of fruit. The type of weather which favours a spring thrips infestation may not be favourable for the setting of fruit. With a wet cold winter followed by an early warm spring the roots may not be able to supply the shoots adequately with nutrients; hot north winds at blossoming time may affect chances of pollination; variation in the viability of pollen in fruit blossom in different years is an important consideration.

RAISING EXPORT PIGS WITH BARLEY AS PRINCIPAL FOODSTUFF.

[By W. J. Spafford, Deputy Director of Agriculture.]

South Australia is rapidly becoming an exporter of pig carcasses to the United Kingdom, and the quality of the meat sent overseas during the past couple of seasons is such that it is bought quite readily. The satisfaction given to overseas buyers of South Australian pork makes it appear that almost unlimited expansion of the pig-export industry can be brought about, provided that only good quality carcasses are shipped. The possibilities of the pig-export industry are very great indeed, because an enormous demand, now largely supplied by foreigners, exists in Great Britain, and cheap grain, suitable for the production of the highest class of pork for conversion into bacon, is grown very cheaply in this country.

BARLEY A GOOD PIG FOOD.

Much of South Australia is well suited to the production of barley, as well as wheat, and even although no serious effort has been made to encourage the growth of barley, the surplus grain of this cereal over and above that required for local malting and brewing is now very considerable, and so far it has been impossible to find an overseas market for more than a portion of the overplus. On the other hand the overseas market for frozen pig carcasses, of a type that will make good bacon, is becoming better and better for Empire countries, and there is no grain which will produce better pork for bacon-making than barley, if used judiciously. The firmness and whiteness of fat, and deneness of the texture of the meat produced when sufficient barley is used in the ration supplied to pigs, is well known to pig feeders and bacon manufacturers, and at present market values it is doubtful if there is any other way to sell barley to greater advantage than if converted to pork.

SOUTH AUSTRALIA IS A FAVOURED COUNTRY FOR THE REARING OF PIGS.

The climatic conditions obtaining in most of the cereal-growing districts of South Australia are almost ideal for the production of pigs with the minimum of artificial protection. Given access to a plentiful supply of water, and provided with a simple sort of shade, such as a low-set brush shed, pigs thrive in most parts of the country.

No serious diseases of pigs are virulent in South Australia, and with ordinary care most pigs dropped are economically reared to marketable size.

Added to the favourable climatic conditions is the advantage attached to cheap grain, for there are few countries in the world which can produce barley and wheat at a lower cost than is done in this country.

THE OVERSEAS MARKET FOR PIG CARCASSES.

As far as Australia is concerned there is only one important overseas market for pig products, and that is the United Kingdom. Between £50,000,000 and £60,000,000 sterling worth of pig products are imported into Great Britain annually, and the great bulk of these are sent from foreign countries. Besides other pig products the United Kingdom imports annually about 9,000,000cwts. of bacon and hams, and almost 1,300,000cwts. of pork. Of bacon and ham about 8,000,000cwts. are secured from foreign countries, whilst almost all of the remainder comes from Canada. Of pork, foreign countries supply about 607,000cwts. and Empire countries about 678,000cwts., and of this latter figure Australia only provides about 82,000cwts.

It has been proved definitely that first-class bacon can be manufactured in Britain from carcasses received in a frozen state from Australia, provided that they are of the right type, and that the pork from frozen porkers thaws out well and sells readily, and so it should be possible to secure a share of this enormous trade in pig products. To be able to do this profitably it will be necessary to produce the type of pig welcomed by British buyers, and not to expect the consumers to pay high prices for something they are not at all keen on, and which is consequently unsuitable for the trade. That they will not do this is amply illustrated by what happened a short while ago to a consignment of a thousand South Australian pig carcasses sold in London on behalf of a local exporter, in which case the carcasses of the required type brought 5½d. per pound, whilst others of the same weight, but carrying much too much fat, realised the low price of 2¾d. per pound.

THE TYPE OF PIG REQUIRED IN GREAT BRITAIN.

It was only a few years ago when the term "British pork" meant "fat pork," but that has been changed, and now-a-days the high-priced bacon and pork eagerly sought in the British markets is of a very lean type, and anything showing much fat is sold at a really low price. In this direction public taste has become very fastidious in favour of lean pork and bacon, and if South Australia is to secure a place in this wonderful market it will be necessary to produce an article of the type required.

Although the change from the attraction of very fat pig products to a fancy for lean pork and bacon came about many years ago in Great Britain, the tradition persisted for some time in this country that the ideal pig was a short, dumpy animal, broad of back, round and heavy in the hams, and carrying a relatively high proportion of fat, and it is only in the last few years that a noticeable change has taken place. Even for local requirements, present-day sales show a strong preference for the properly finished lean type of porker and baconer, and whilst free choice is possible, nearly twice as much per pound is paid for long-bodied, deep-sided pigs as for short animals of equal weight, but carrying the amount of fat that was insisted upon only a few years ago. The popular pig of to-day would have been considered to be in forward store condition in days gone by, and no one would have thought of killing such an animal for bacon or pork.

Although it is *important* to send pigs to local markets in this old-time "forward-store" condition if it is hoped to obtain anywhere near top prices, it is *essential* to produce this type of pig if any increased numbers of carcasses are to be successfully marketed in Great Britain.

To suit the requirements of the British market the type of pig and the condition carried are similar whether for the porker or baconer trade, the only difference being that of weight of carcass, and this type is described in the recent publications on the subject of the *British Ministry of Agriculture and Fisheries* as:—

Head with jowl and neck should be light. This portion consists largely of bone and is therefore of low value, and on that account requires to be light, and should not carry rolls of coarse fat at jowl or over the neck.

Shoulders and fore-end must be light and free from wrinkles and coarseness. The "collar" containing overlapping muscles and much gristle is a cheap cut.

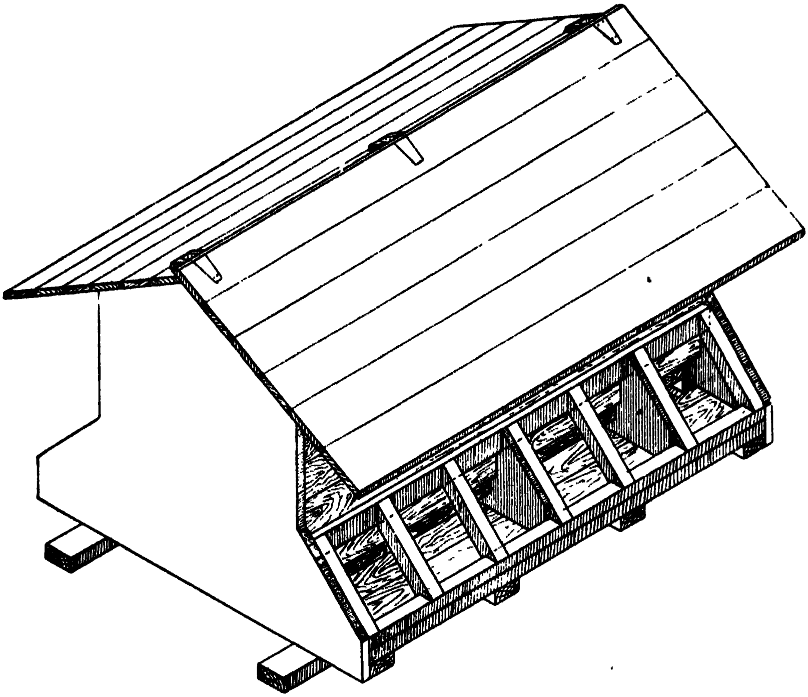
Back must be long and level because the middle of the carcass fetches the highest price per pound. Length means quantity of the most valuable portion, and a level back means weight and depth of loin. The fat on the back should not exceed 1½in. in thickness in baconers, and should be considerably less in porkers.

Sides should be level and moderately deep. Distension of the lower part is often accompanied by thin belly cuts, and disproportionate primary offals. Moderately deep sides afford good depth of prime back cuts and under cuts.

Underline must be straight as it denotes that the "thin streaky" and "flank" cuts are not unduly distended and thin.

Belly should be thick in the flesh, as the value of lower cuts is increased by thickness.

Flank should be thick, handle firm, and be in line with the sides.



—— ISOMETRIC VIEW OF PIG SELF-FEEDER. ——
—— TO SHOW SIDE AND BRACINGS ——

A Self-feeder for Pigs for Use in the Field.

Where pigs are being fattened in paddocks, self-feeders are invaluable. To produce good-type market pigs from the breeds or crosses which tend to fatten to too great a degree the animals should be fed from troughs until being "finished" for market. By following this method they can be compelled to grow without becoming excessively fat. For the leaner types of pigs self-feeders can be used most of the time.

Hams must be broad, wide, and deep to hocks, as these characteristics denote plenty of flesh. There should be no depression between the hams at the root of the tail, as this indicates excessive fat.

Tail should be set high as it is held that it denotes a higher proportion of flesh than if set low; on the other hand a tail set too high frequently denotes an excess of back fat.

Legs should be set wide apart, and the pig should stand well up on the tips of the toes.

Bone must be fine, as it indicates quality and does not detract from weight.

Skin should be free from coarseness and wrinkles.

Hair should be fine.

Colour may be anything, but the trade prefers white pigs.

Weights should range between 160lbs. to 225lbs. live weight (120lbs. to 170lbs. dressed weight) for baconers, and 85lbs. to 120lbs. live weight (60lbs. to 90lbs. dressed weight) for porkers.

Good conformation does not necessarily connote good quality of meat, which is largely dependent upon feeding. Breeding exerts the great influence on general conformation, and feeding on the quality of the flesh. Feeding determines the colour and texture of the flesh, and to some extent the quality of the bone.

DEFECTS COMMONLY FOUND IN CARCASSES.

The defects which are most common in carcasses received by English bacon factories and butchers are as follows:—

Short Middle.—Great differences are found in the length of side, and it is not unusual for sides of the same weight to vary 4in. or even more in the measurement taken from top of the first rib to the end of the round bone. The proportion of the valuable middle cuts is much greater in the longer sides, and the shorter sides are heavier in the shoulder and carry thick back-fat.

Excess of Fat.—Sides which contain heavy excess of back-fat are almost unsaleable. If the back-fat is thick the whole carcass is similarly affected.

Soft Fat.—The presence of soft fat is usually an indication of wrong feeding methods. Many distributors hold that the solidity of the fat is a conclusive test of quality, and that the belly-fat affords a better test than the back-fat.

If the fat is firm and white, the bacon will be of the highest quality.

Heavy Shoulders.—A coarse framework of bone at the shoulder, with its accompanying weight of flesh, and particularly if accentuated by too much fat, makes its sale very difficult.

Thin Belly.—Unduly distended bellies are so stretched that the rashers cut from "flank" and "thin streaky" are excessively narrow.

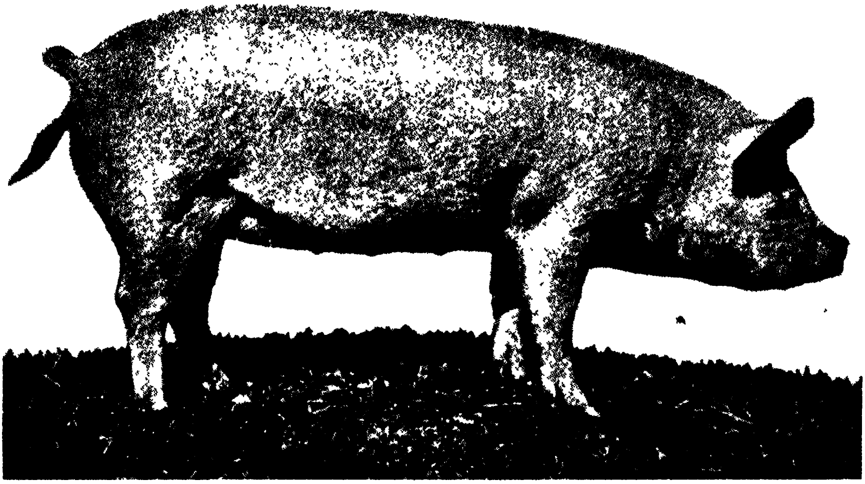
Seedy-cut.—Seedy-cut, which is a pigmentation about the milk ducts, is usually found in the female progeny of black boars; it is not in itself harmful, but, owing to its objectionable appearance, the parts affected must be removed from the side before sale. Apart from disfiguration, this may mean the removal of 7lbs. or 8lbs. of bacon from a valuable portion of the side. Seedy-cut can be avoided by using a white boar.

MEASUREMENTS OF IDEAL CARCASSES.

In discussing the judging of bacon by a standardised chart of measurement, in the Silver Jubilee number of Empire Pork Review, Mr. John Hammond, F.R.S., Professor of Agriculture, Cambridge, says, amongst other things:—

The weights of carcasses in greatest demand are those from 140 to 170lbs. for the Wiltshire side trade, which forms the bulk of the bacon consumed in England. Bacon may be made from heavier or lighter carcasses than these, but it does not command the highest price and has only a limited sale.

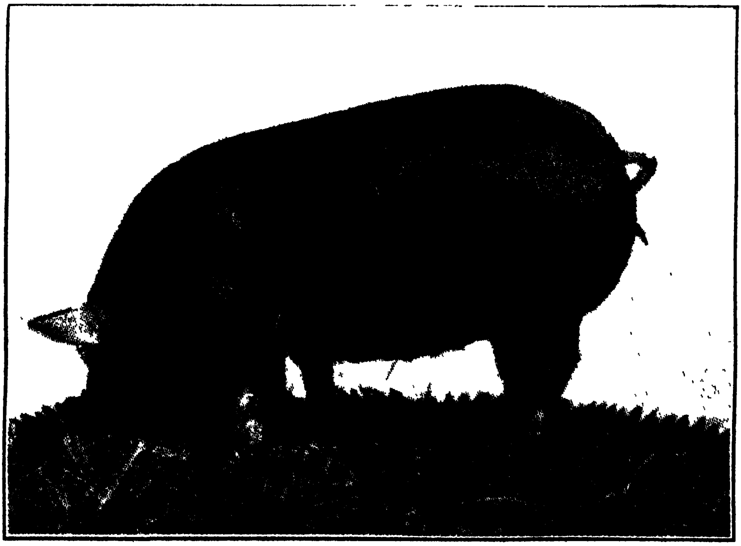
Length of side, thinness of back fat, and thickness of streak (belly), are the three main points which can be measured in commercial carcasses to be made into bacon, for they do not involve cutting through the side.



An Ideal Type of Pig for Present-day Market Requirements.

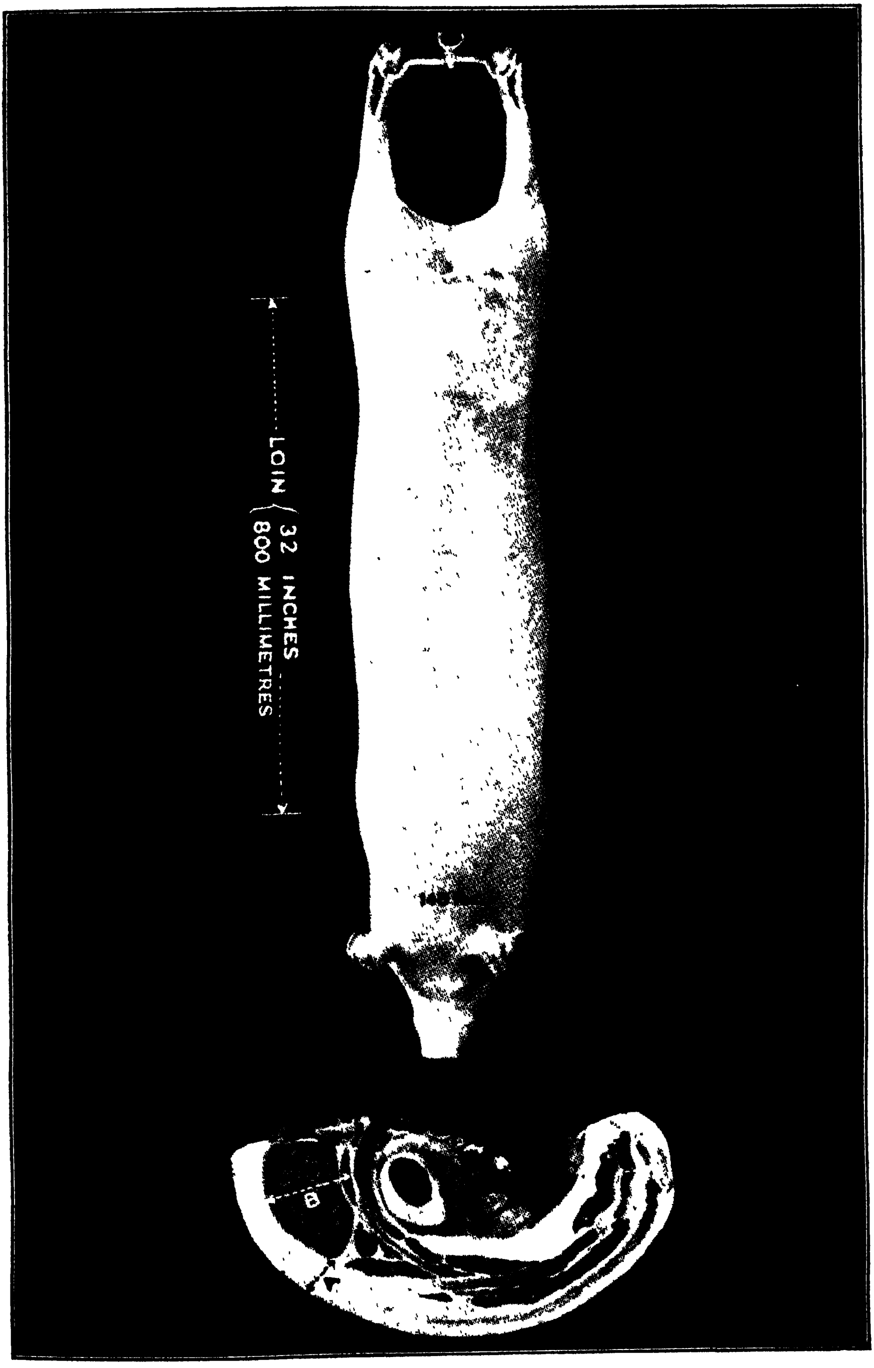
The fat bacon and pork, which had ready sale in Great Britain a few years ago, is only saleable at low prices at present, for fashion has changed towards a well-finished pig of a relatively lean type. Market pigs must be long and deep of body, with nicely rounded hams, light and fine at the shoulders, and possess relatively small heads.

The animal illustrated fulfils all of the requirements of both the British and local markets, and if South Australia is to capture a noticeable share of the overseas trade in pig products pigs of this type must be bred and reared in large numbers



A Market Pig of Incorrect Type Either for Bacon or Pork.

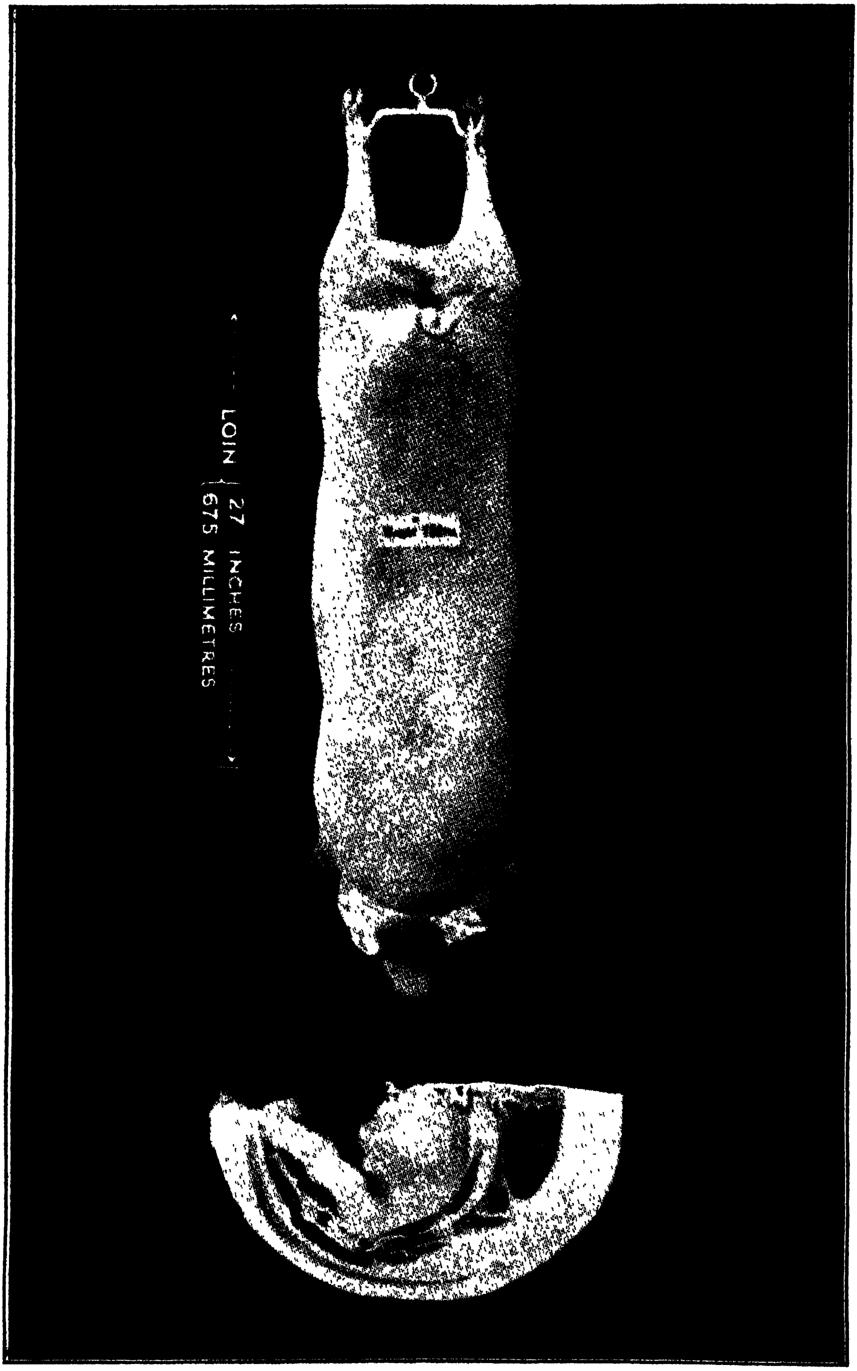
The short, dumpy pig, broad of back, round and heavy in the hams, and carrying a relatively high proportion of fat, no longer sells well in either British or local markets.



[From *Empire Pork Review—Silver Jubilee Number.*

An Ideal Baconer.

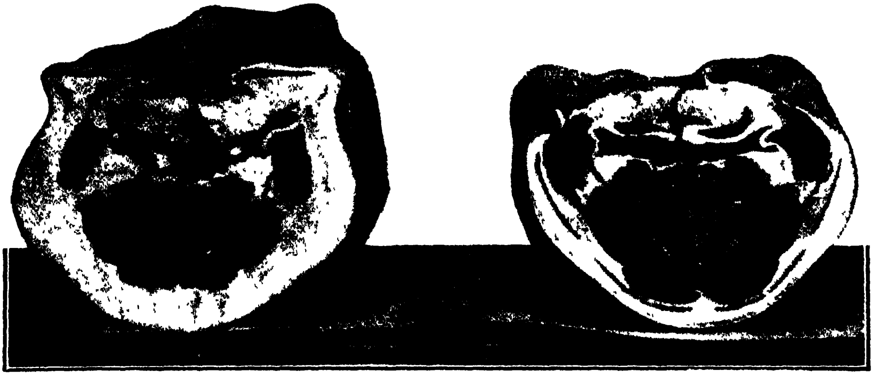
Such a carcass is ideal for present-day British requirements, the length between the round bone and the first rib being 32 inches, the thickness of the "eye" of meat (B) being 2¼ inches, and the fat at base of the "eye" of meat (A) being only 1 inch thick.



[From *Empire Pork Review—Silver Jubilee Number.*

An Unsuitable Baconer.

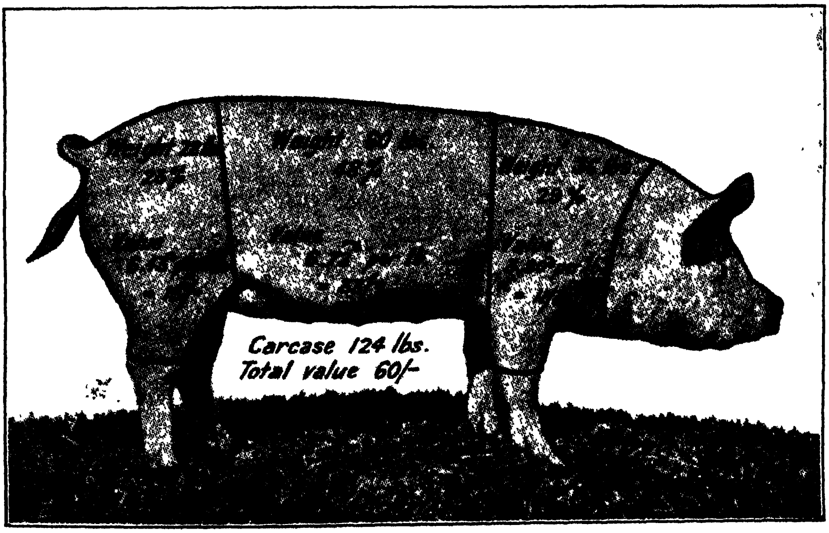
Such short, dumpy carcasses (27 inches between round bone and first rib) are not favoured in Great Britain. The cross-section shows a thin "eye" of meat, and lots of fat.



[From *The Pig Industry*, by R. B. Kelley.

Lean Pig Meat Preferred.

The illustration on the right shows the high proportion of lean to fat desired to-day, whilst that on the left shows the once popular quality, which is now considered to be much too fat, and so is of low market value.



Why Pigs with Long, Deep Bodies and Light Forequarters have High Market Value.

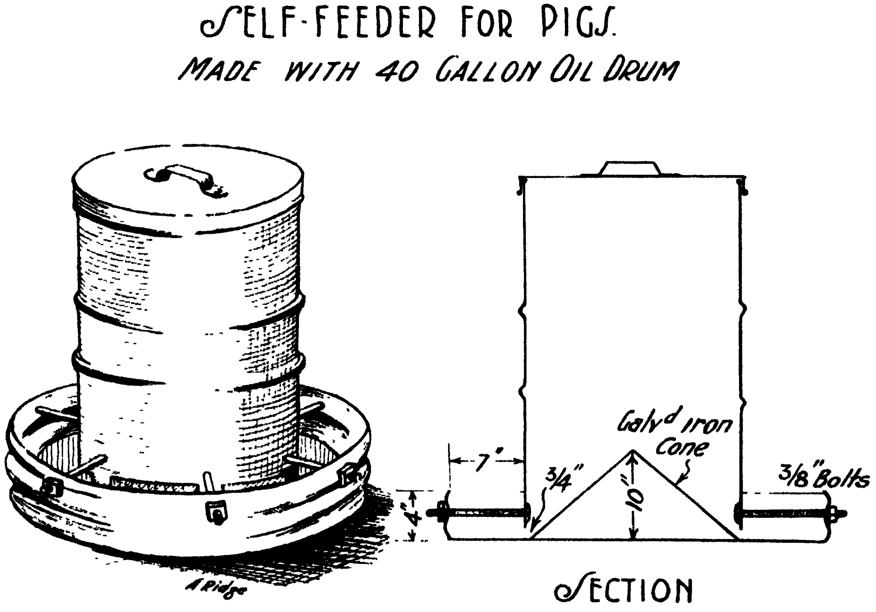
Nearly half of the weight of the ideal market pig is in the middle section, and as the average price of this section is higher than that of either of the other sections, this portion is worth considerably more than half the total value of the carcass. The lighter the forequarters the better, because the market value of this section is so low.

Note.—The weights of the sections and their relative values are taken from "Pig Keeping" (Bulletin No. 32 of the Ministry of Agriculture and Fisheries, London), whilst the total value is the actual price at Adelaide Abattoirs on 8th January, 1936, for good pigs of the weight shown.

Length for Weight.—A good standard carcass (150 to 159lbs.) should measure 820 mms.* (32½in.) or more from the pelvis or head of the femur (round bone) to the first rib. For each increase of 10lbs. carcass weight above 150lbs. the length should increase by 20 mms. (¾in.).

Thinness of Back Fat.—The thickness of the back fat is greatest over the shoulder, thinnest over the last rib, and intermediate between these two over the rump. In a good, standard carcass the fat should taper down from the shoulder (40 mms. or 1½in.) to the last rib (22 mms. or ⅞in.).

Thickness of Streak.—This is taken in conjunction with thinness of back fat. The streak can be made thick by increase in the thickness of the lean meat, or by the addition of fat. It is the former which is required, so that where the carcass cannot be cut through to see the composition of the streak, the thickness of the streak is judged only in relation to the thinness of the back fat. Where the thickness of the back fat is right a good standard carcass should measure 40 mms. (1½in.) and increase by 1 mm. for each 10lbs. increase in carcass weight. A good estimate of the thickness of the lean meat in the streak can be obtained by subtracting the thickness of the back fat at the last rib (22 mms.) from the thickness of the streak (40 mms.), which leaves the balance (18 mms.) as an estimate of the lean. If the back fat is thick (30 mms.), at the same streak thickness (40 mms.) the measure for the lean would be less (10 mms.).



Self-feeder for Pigs Made with 40-gallon Oil Drum.

Forty-gallon oil drums make effective self-feeders for pigs, and are easily moved from one position to another in the fields. Anyone with a little experience in plumbing can construct a serviceable self-feeder from an oil drum, a few bolts, and a little galvanized iron.

Mr. Hammond continues by stating that if the side can be cut through before judging, then the thickness of the lean meat can be measured directly by taking the *thickness of the "eye" of the loin* from a cut made at the last rib. This position is selected because it is the most valuable cut and because it is the latest maturing part of the body, so that if the thickness of the lean meat is right here it will be elsewhere. The "eye" in a good standard carcass should measure 55 mms. and increase 1 mm. for each 10lbs. increase in the carcass weight.

* 25 millimetres to 1in.

PRODUCING THE PROPER TYPE OF PIG.

If South Australia is ever to become the important pig-breeding country its natural advantages of favourable climate and plentiful supply of suitable grain appear to indicate, pig carcasses must be exported to Great Britain. If the British market for pig products is to be successfully exploited only the very best quality of carcasses must be exported. To produce the type of carcass required in Great Britain, breeders must realise that the type of animal that has been generally popular until quite recently, and is still so with some pig-keepers, must be replaced by a different-shaped animal. Short, dumpy, fat pigs are of low value in Britain, and at present prices are unprofitable to export. The type of pig which brings top market prices overseas is a long, lean, rangy animal, deep in the side, light in the head, neck, and shoulders, straight on the underline, with well developed hams, of a white colour, and in a condition which was generally looked upon in this country as *forward store condition.*

SECTION A-A

Plan of Self-feeder for Pigs (for use in Sties).

Where large numbers of pigs are to be fattened in sties, it is essential to provide self-feeders to keep down costs of feeding. The simple self-feeder here shown is very effective when crushed grains are the principal foodstuffs used, and considerably reduces the cost of production.

The right condition is developed by careful feeding, and is particularly helped by allowing the youngsters plenty of freedom and exercise until they are getting close to marketing weight. Leanness resulting from under-feeding is not the kind of condition desired.

The great bulk of the pig carcasses imported by Britain for which top prices are secured are sired by Large White boars and there is no breed so suitable as sires for this purpose, because of the high proportion of animals of correct type got by them.

Almost any prolific, roomy sow is suitable to mate with a Large White boar to produce pigs which will grow into export animals if fed correctly, but of the sows usually available in this country the order of preference would be something like:—

1. Half-bred Tamworth-Mid York.
2. Half-bred Tamworth-Berkshire.
3. Tamworth.
4. Canadian Berkshire.
5. Half-bred Berkshire-Mid York.
6. Mid York.
7. Berkshire (old type).

UTILISING BARLEY TO BEST ADVANTAGE.

Best results are obtained from the feeding of barley to pigs if the grain is thoroughly crushed, but it is not always economical to go to the expense of crushing. If not crushed the grain can be soaked with water, or fed dry and whole. The relative feeding values of various treatments of barley for pig feeding are somewhat as follows:—

4lbs. of ground barley will produce 1lb. of live weight of pig.
4½lbs. of soaked barley will produce 1lb. of live weight of pig.
5lbs. of dry, whole barley will produce 1lb. of live weight of pig.

To soak the grain properly, just the quantity of water which the grain will absorb should be used, and never an excess of water. All of the barley put into soak one day should be used within 24 hours, and vessels used for soaking should be thoroughly cleaned every day.

No advantage is to be gained by cooking barley for pigs.

Wherever possible barley should be fed to pigs in conjunction with skim milk and greenfeed, but if no skim milk is available a pig meal or meat meal of some kind should be used.

After the experimental work conducted at Turretfield Experimental Farm, with the feeding of barley to pigs, Professor Perkins recommends:—

1. Where Skim Milk is Absent, but Greenfeed is Procurable.

For sows with average-sized litters, 6½lbs. of crushed barley and 1½lbs. of pig meal should be fed daily for the first week. The daily allowance should be then increased each week by about 1½lbs. of crushed barley until weaning time. Throughout the period sufficient greenfeed or roots should be supplied.

Young growing pigs should receive per day:—

50lbs. live weight	2lbs. crushed barley, ½lb. pig meal
60lbs. live weight	2¾lbs. crushed barley, ⅝lb. pig meal
70lbs. live weight	3½lbs. crushed barley, ⅝lb. pig meal
80lbs. live weight	4¼lbs. crushed barley, ⅝lb. pig meal

2. Where Skim Milk and Greenfeed are Available.

Porkers (80lbs.); 1½lbs. crushed barley and 3lbs. pollard; or 2¼lbs. crushed barley and 2¾lbs. bran; or 2lbs. crushed barley and 2lbs. crushed peas.

Light Baconers (150lbs.); 2lbs. crushed barley and 5lbs. pollard; or 3½lbs. crushed barley and 4lbs. bran; or 4lbs. crushed barley and 2¼lbs. crushed pease.

Heavy Baconers (200lbs.); 3lbs. crushed barley and 5½lbs. pollard; or 4½lbs. crushed barley and 5lbs. bran; or 5lbs. crushed barley and 2¾lbs. crushed pease.

STANDARD RATION FOR PIGS.

In feeding tests conducted at Roseworthy Agricultural College the standard ration consisted of:—

Crushed barley	8 parts
Crushed wheat	4 parts
Crushed pease	2 parts
Meat meal	1 part
Greenfeed	12 parts

MINERALS FOR GROWING PIGS.

It is generally recognised that more rapid gains in live weight and the general health of growing pigs, are secured if some minerals are added to the foodstuffs being supplied. On this matter, Mr. Alan H. Robin, B.V.Sc., Government Veterinary Officer, makes the following remarks:—

Mineral matter is of the greatest importance to young growing pigs, being required for the maintenance of vital body functions and the growth of sound bone. It also assists in the building up of the food proteins into muscular and other body tissues. A deficiency of it leads to unthriftiness, poor development, and the occurrence of disease such as depraved appetite, paralysis, and rickets. So if they are to remain healthy and make rapid growth their diet must contain supplies of it ample for their needs. While all foodstuffs contain various minerals required by pigs, the amounts present vary very considerably, *e.g.*, some foods are rich in calcium, others are poor in it, &c. Should there be any danger, therefore, of the ration supplied being short to any serious extent of the animals' requirements of them, then a mineral supplement should be fed in order to make good the deficiency.

The only mineral constituents that are ever likely to be lacking to any serious extent in rations fed ordinarily to pigs from weaning to marketing condition are Calcium (lime), Phosphates, and Common Salt ($NaCl$).

If it is desired to provide the necessary minerals in the form of a mixture, the following will fully supply the need:—

Ground limestone or agricultural lime	2 parts
Bonemeal or dicalcic phosphate	2 parts
Common salt	1 part

One pound of the mixture to be added to every 40lbs. of dry foodstuff being supplied to the pigs.

There is no advantage to be gained from the addition of iron, sulphur, iodine, &c., to mineral mixtures for pigs.

It is necessary to point out, in conclusion, that an adequacy of minerals in the diet of growing pigs is not of itself sufficient to ensure good results; the animals must also have conditions whereby they can utilise the minerals. This necessitates their obtaining a liberal supply of Vitamin D—the anti-rachitic factor that controls the assimilation of minerals and an absence of which will cause unthriftiness, paralysis, and rickets to develop, even though minerals be abundantly present. Sunlight is the most potent (and also the cheapest) supplier of this essential vitamin, and pigs running out in the open and exposed to it will, of course, receive all they require of it. If, however, they are confined to sties, these should be so constructed that they will let in plenty of sunlight. Greenfeed is also well supplied with Vitamin D and can advantageously be fed.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. CLARKE, B.Sc., Botanist at the Roseworthy Agricultural College.]

Nos. 17 and 18.—CAPE TULIPS.

(*Continued from page* 533.)

Differences Between the Two Species.—Examination of the open flowers of the two *Homerias* reveals marked differences in the structure of the style and its branches. In *Homeria collina* the slender style divides up into three flattened petaloid branches, which are quite free and from 5 to 8 mms. long, becoming broader towards their free ends. Along the upper surface of each branch runs a petaloid crest consisting of two lateral membranous flaps, one on either side of a central groove which terminates in a stigma. Towards the end of the branch these lateral flaps are prolonged forwards, the free portions forming a divided upper (or inner) lip with the stigmatic surface between it and the main part of the stylar branch which thus forms a lower (or outer) lip. In the young stages of the flower the stylar branches are folded together; but later on they open out and, becoming turgid, press outwards the upper parts of the respective anthers. The two lips of each branch, which were at first appressed and somewhat flaccid, now become widely opened, thus exposing the stigmas. When fully turgid the lower lip is curved outwards and may be partially wrapped round its contiguous anther; the upper lip is reflexed and appears as a pair of pointed, ear-like, flaps, projecting upwards and backwards.

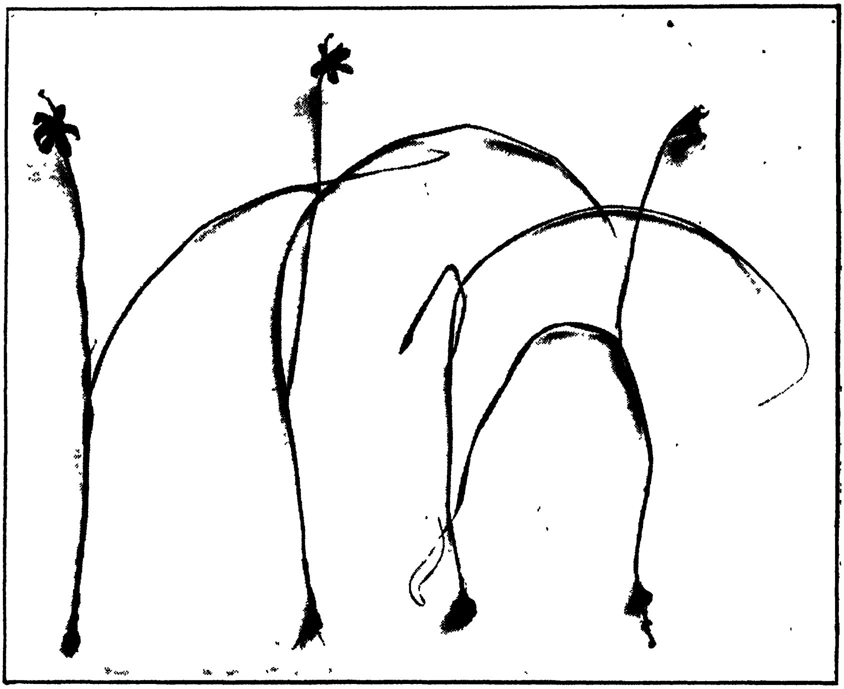

Fig. 1.—One-leaved Cape Tulip, *Homeria collina* var. *aurantiaca*. (See coloured plate opposite.)

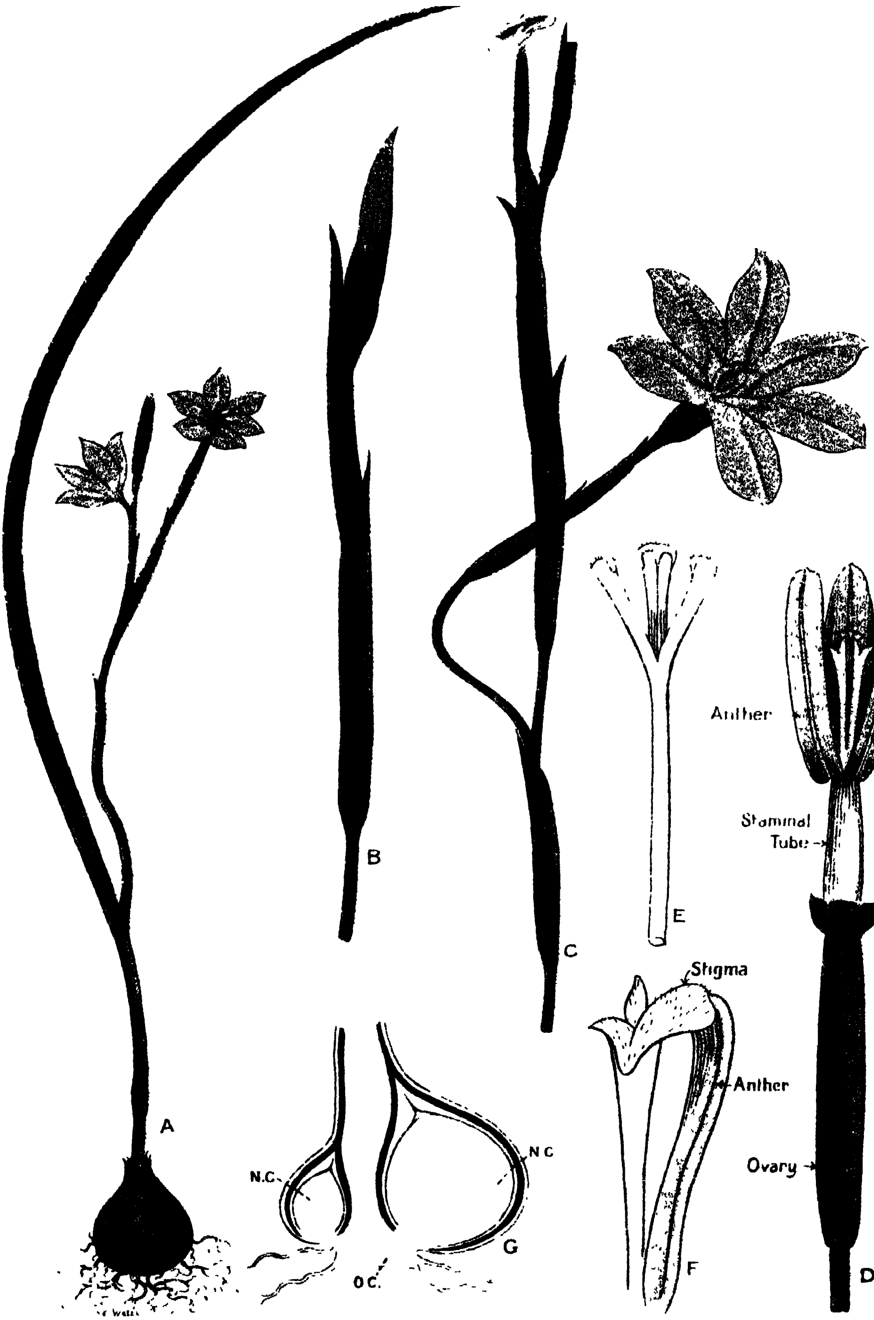
In *Homeria miniata* the stylar branches are coherent except at their tips, the free parts being less than 1 mm. in length. The fused branches form a dilatation at the end of the style, shaped like an inverted pyramid, strongly compressed



ONE-LEAVED CAPE TULIP (*Homeria collina*, Vent., var. *aurantiaca* (Sweet) J. G. Baker). A.—Single plant in flower showing corm (x 1/3). B.—Portion of young flowering stem, showing flower bud emerging from spathe valves (Nat. Size). C.—Older branching stem showing open flower and developing fruits (Nat. Size). D.—Flower with perianth removed to show arrangement of stamens and pistil (x 3). E.—Style and its branches (x 4). F.—Single style branch viewed from the side in the fully expanded and turgid condition, showing the stigma and relationship to the neighbouring anther (x 10). G.—Base of plant in longitudinal section showing developing corms (n.c.) and remains of

laterally between the three projecting angles of the inverted base. These angles correspond in position with the intervals between the three anthers, so that, at first sight, the stylar branches appear to alternate with stamens. Closer examination, however, reveals that the points or angles, which are slightly notched, represent the lines of junction of the stylar branches which thus are represented by the sides, and not by the angles, of the inverted pyramid, and correspond in position with the anthers, as is usual in the family. When opened out each style branch presents a shallow notch and appears slightly bilobed, and this feature, taken in conjunction with the arrangement of the petaloid crests, is such that the stigma appears to be bordered by lateral, instead of by antero-posterior, lips. While the stigmatic surface is continuous with a groove as before, the lateral membranous flaps are not continued forwards as free portions, but diverge obliquely outwards and become continuous with the lateral margins of the branch. These differences will be apparent by comparing figure E of the coloured plate facing page 528 (November, 1935) with figures E and F of the coloured plate in this issue.

For purposes of clearness the more important differences between the two species of Cape Tulip are set forth in the following table:—

Homeria miniata.	*Homeria collina*, var. *aurantiaca.*
Produced leaves 2, together with a third shorter leaf supporting the inflorescence.	Produced leaf 1.
Nodes of stem swollen, due to presence of cormils in the leaf axils	Nodes not conspicuously swollen.
Corms formed below the ground; cormils formed both above and below ground	Corms only, formed below the ground.
Tunics of corms black and fenestrated	Tunics thicker, brown in colour.
Plants growing in dense clumps	Clumps smaller.
Stem not noticeably flexuose, often supported by third leaf	Stem weak and flexuose below the inflorescence.
Branches and flowers numerous	Branches and flowers few.
Flowers smaller; perianth segments less than 1in. in length	Flowers larger; perianth segments 1-1½in. in length.
Flowers mostly salmon-pink; base of perianth segments yellow, spotted with green.	Flowers varying from orange-scarlet to salmon-pink; perianth segments yellow at the base.
Staminal tube swollen and glandular-hairy at the base, longer than the anthers	Staminal tube uniform, glabrous, scarcely as long as the anthers.
Anthers less than 5mm. long	Anthers 7-10mm. long.
Style branches coherent	Style branches free.
Ovary less than ½ inch long	Ovary nearly 1 inch long.

Life History of Two-leaved Tulip.—The Cape Tulips are usually described as being perennial, and, from a practical viewpoint, they should be regarded as such, since new plants invariably appear at the sites of those of the previous season. In the strict sense, however, the perennial habit is by no means universal, nor is it necessarily the rule. Plants arising from corms, or from cormils, do not necessarily retain any organic connection with those from which such corms or cormils were produced. A fact of importance in this connection is that the production of a stem with flowers definitely terminates the life of an individual plant. Consequently, the time which elapses between the germination of a corm or cormil produced in the leaf axil of a parent and the flowering of the resulting Tulip measures the duration of life of the plant concerned. And from this point of view it is probable that the plants may be either perennial or biennial, or even annual, depending upon the size of the corms, the depth at which they are situated in the ground, and to some extent perhaps also on the seasonal conditions. The smaller the corm, the deeper its level in the soil, and the more unfavourable the conditions for germination and growth, the longer will be the period between germination of the corm and flowering of the resultant individual. Thus the cormils doubtless give rise to perennial or biennial plants, while those arising from medium sized and larger corms are probably most often biennial or annual in habit.

Apart from their size, the corms and cormils are essentially similar structures. Each consists of a roughly globular axis or stem enclosed within one or two thicknesses of scale leaves, of which the outermost are very tough and serve as a hard protective covering, while the innermost contain starchy reserves and appear white in colour. The scale leaves are thickened towards the tip of the corm where they taper to a point, so that, viewed externally, the corm appears pointed. The axis or stem is composed of cells filled with reserve materials, and bears at its tip a small terminal bud, appearing as a minute greenish-yellow point, and consisting of a rudimentary stem surrounded by the primordia of leaves. The plant which subsequently develops is formed from this bud which grows at the expense of the reserves present in the main body of the corm. A second, more rudimentary bud is placed a short distance away (about 5 mm.) from the terminal bud, and appears as a small greenish-yellow spot. The function of this second bud is not clear, but it probably develops into a plant if the terminal one is injured. Thus the corm consists, in the first instance, of two internodes of swollen stem tissue enclosed within scale leaves.

When germination begins the substance of the corm, which is at first hard, becomes softer, and, if abundant moisture is present, it gradually assumes a more translucent appearance due to conversion of the starchy material into a colloidal or more soluble form. Meanwhile the terminal bud begins to grow and rootlets appear from near the base of the bud leaves. During the first year, and perhaps for a number of successive years, growth consists in the development, from below upwards, of a succession of leaves, the lowermost and outermost of which early become withered and frayed, forming membranous protective sheaths at the base of the single, much longer, green leaf, which appears above ground and constitutes the entire aerial growth during the first and subsequent preflowering seasons. Among a clump of Cape Tulips it is always possible to find growing amongst older flowering individuals a certain number of plants consisting each of a single very long linear grass-like leaf connected below ground with a corm, with the remains of the corm of the previous year attached to its base below the level of insertion of the slender rootlets. These young Tulips are liable to be confused with another South African plant of similar habit, namely, *Moraea xerospatha,* distinguishable from *Homeria* by its pale heliotrope flowers.

As the season advances a new corm is formed by enlargement of the internode immediately above the insertion of the single green leaf, the base of this leaf becoming expanded and fibrous to form the protective covering or tunic for the developing corm. Thus, during the preflowering seasons, new corms are formed by the successive enlargement of the internodes, from below upwards, of the original terminal bud, the apex of which remains dormant until the plant is ready to produce flowers. Such corms, one of which is formed each year, tend to become progressively larger and more deeply situated in the soil, especially in the case of plants originally developed from cormils. This brings about an apparent upward displacement of the tunics of the previous year corms.

The development of a flowering stem depends upon the growth upwards of the axis of the original bud and the lengthening of the internodes between its successive leaves. This is accompanied, in *Homeria miniata,* by the formation of axillary corms and cormils at each node. If a section be cut longitudinally through an entire plant in the plane which includes both leaves and stem, the latter will be seen to be continuous at the base with the shrunken remains of the previous year's corm, the persistent tunic of which remains as a protective covering, and may itself be surrounded in turn by the remains of previous tunics; there may, in fact, be a number of concentrically arranged tunics with numerous cormils between them, and representing the bases of former leaves of the existing plant, and outside these there may also be the semi-decayed remains of tunics belonging to the parent plant from which was derived the original corm that gave rise to the individual under examination.

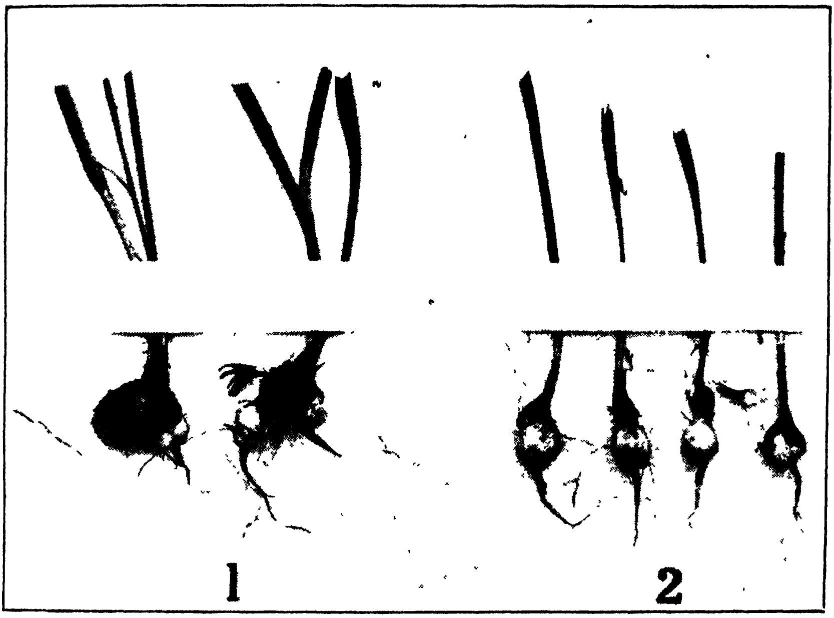


Fig. 2.—Two-leaved Tulip. 1. Base of young plants growing at site of plant of previous year. Note stout contractile roots, which draw down the corms to deeper levels in soil. 2. The same separated out. Note upward displacement of corm scales.

The two lowermost nodes of the stem, situated below the ground and immediately above the level of the old corm, bear corm scales or leaves in whose axils are developed lateral corms and cormils. These axillary structures are formed, in *H. miniata,* as parts of a branching system. There is a single large corm which is sessile in the axil and represents the terminal part of the axillary branch, and below this arises a dense cluster of cormils of various sizes connected by stalks of varying lengths to a short branching axis. The two oppositely placed systems of corms and cormils are equally developed and cause two pronounced bulgings, one on either side of the base of the stem. They are enclosed by the subtending corm scales which extend upwards, above the ground level, as protective sheaths to the lower part of the stem.

The internodes above the insertion of these subtending scales are greatly elongated, the next nodes being all above the ground. The lowest two nodes above ground level give attachment to the produced leaves which may be from 1½ft. to 2ft. in length. These leaves are V-shaped in cross-section at the base, and are termed *equitant* (literally "astride"), the stem being clasped by the two arms of the V. The nodes at which these leaves arise are swollen due to the presence of cormils in their axils. In addition to the two long leaves there is usually a third, much shorter, leaf, similar in structure to the first two.

The remainder of the stem consists of the branched inflorescence. The branching occurs in a curiously zigzag manner. Each node is protected by a short leaf, or bract, in whose axil arises a number of minor inflorescences on peduncles of varying lengths in addition to occasional branches similar to the first. Each minor inflorescence consists of a small cluster of flowers enclosed within spathe leaves from which they emerge and open successively. The flowers open widely in sunlight, but tend to remain closed in shade or during dull weather. The perianth of the flower is extremely delicate and withers early, becoming twisted around the stamens and style surmounting the ovary, which enlarges somewhat to form a club-shaped fruit or capsule.

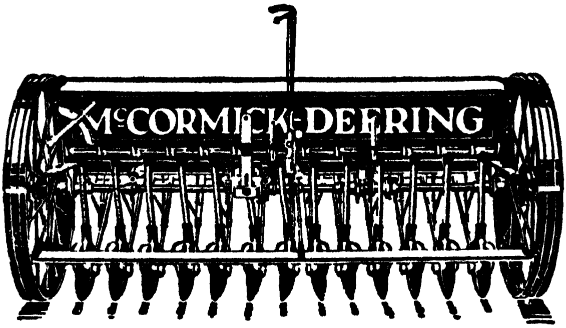
When the flowering stem dies down, the corms and cormils formed in the axils of leaves and corm scales lose all connection with the plant and remain dormant in the ground until the following year when each one is ready to produce a new individual. This means that a cluster of new plants will appear at the site previously occupied by the parent. Several hundred cormils may be formed by a single individual. By repeating the same method of cormil formation dense patches of the Tulip are produced, and, if one of these patches is uprooted, many hundreds of corms and cormils will be found clustered together in a dense, almost spherical clump (See Figure 3).

The enlargement of a clump and the separation of its constituent individuals are assisted by the descent of the corms into the ground. During germination one of the roots becomes thickened and contractile, drawing down the corm, away from the old tunic and subtending scale, into a deeper part of the soil. Thus Cape Tulip, like the Soursob (*Oxalis cernua*) possesses contractile roots, but the mechanism of contraction is, in this case, quite different from that seen in *Oxalis.*

Life History of One-leaved Tulip.—In *Homeria collina* the general course of the life history is similar to what obtains in the case of *H. miniata*, but the end results are somewhat different, owing, chiefly, to the smaller number of corms produced per plant. As before, the individuals doubtless comprise perennial, biennial, and annual forms. A longitudinal section through the base of a flowering plant shows that the lateral corms arise singly in the axils of the corm scales, and that, of the two formed at the base of the stem, one is considerably larger than the other, so that one side only of the base of the plant shows a conspicuous bulging, the other side appearing somewhat flattened due to contact with another corm belonging to a sister plant, and representing the smaller of two sister corms belonging to the earlier generation, the larger one having given rise to the plant under consideration. In other words, of the two axillary corms present at the base of this plant (see figure G of coloured plate) the larger one will grow, during the next season, into a flowering plant similar to the one figured, whereas the smaller one will produce an individual which will not flower until the following year. Thus the absence of cormils, and the unequal development of corms at the base are the main differences between the two Tulips as regards vegetative multiplication. Another point of difference is seen in the tunics which, in *H. collina,* are thicker and browner in colour than those of *H. miniata.*

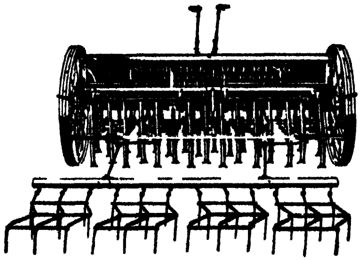
Begin with . . .
a Perfect Seed Bed

You leave nothing to chance if you use these tried and trusty implements in the preparation of your seed bed. For a great number of years they have been renowned for good work wherever grain is grown.



McCORMICK-DEERING GRAIN DRILLS

● Available in disc and hoe types in various convenient sizes With double run feed cups adjustable fertiliser feed positive chain drive on grain and fertilizer feeds and other excellent features these drills will give a good return in the form of bigger and better crops



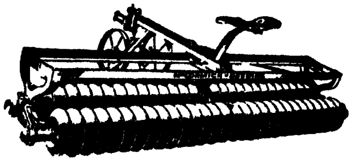
McCormick Deering Cultivator Drill with Levelling Harrow

McCORMICK-DEERING CULTIVATOR-DRILLS WITH LEVELLING HARROW

● The McCormick Deering cultivator-drill is made in sizes to suit all requirements and is equipped with convertible lifting levers for use with tractor or horses The tines are spaced 3½ inches apart and are fitted with 4 inch points so arranged as to cut all the soil The levelling harrow is light in weight with teeth made of spring steel, and has ample clearance for rubbish It is made in sizes to fit all McCormick Deering cultivator drills.

McCORMICK-DEERING SOIL PULVERIZERS

● The McCormick-Deering soil pulveriser helps you to make a perfect seed bed It is a combination roller, pulveriser, cultivator, and packer Crushes lumps, packs loose soil, flattens out air spaces, conserves moisture Two sizes with rolling widths 3½ and 9½ feet



McCormick-Deering Soil Pulverizer

GRUBBING

IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A

MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK.

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling
The Standard equipment will clean up everything over 1½ acres from one anchorage.
Each part designed for simplicity, easy handling and long trouble-free service.

A TIME SAVER AND PROFIT MAKER

ADELAIDE STOCKISTS—Australasian Implement Co., Colton, Palmer & Preston, Harris Scarfe Ltd., McPhersons Pty. Ltd., South Australian Farmers' Union.

TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.

When the returns from the whole seventeen centres were averaged the following results were secured:—

No manure—18bush. 59lbs. of wheat per acre.
1cwt. of carbonate of lime—18bush. 33lbs. of wheat per acre
1cwt. of superphosphate—23bush. 28lbs. of wheat per acre.
1cwt. of superphosphate, 1cwt. carbonate of lime—22bush. 25lbs. of wheat per acre.

NO ADVANTAGE GAINED FROM CARBONATE OF LIME.

From these figures it will be seen that the returns from the "no manure" and "1cwt. of carbonate of lime" plots were practically equal, indicating that no advantage was gained by the use of the latter.

A similar condition of affairs exists when the yield from the superphosphate plots is compared with that from the area receiving both superphosphate and carbonate of lime.

On the other hand, if the return from plots receiving 1cwt. of superphosphate is compared with that from those receiving an equal weight of carbonate of lime, it will be noted that there is a very marked advantage in favour of the former; in fact, practically 4½bush. of wheat to the acre.

Reviewing the results, therefore, an application of lime has not brought about an increase in yield over and above that from the "no manure" plot. Further, a combined dressing of superphosphate and lime has not given a greater quantity of wheat than the plot receiving superphosphate only. Consequently, no recommendation in favour of this material is possible.

It is true that the foregoing returns are the result of a single season's work, but it is most unlikely that weather conditions would affect the comparative yields to any extent. It is considered that, within limits, no matter what type of season was experienced, the influence would be the same on both the limed and unlimed plots. Consequently, as the experiment was fully replicated and conducted under a variety of soil conditions, it may be accepted that the results obtained are conclusive so far as the fertilising effect of carbonate of lime applied to wheat crops in this State is concerned.

It is, therefore, definitely stated that carbonate of lime must, on the average, cause distinct financial loss if used as a manure for cereal crops.

Reference has already been made to the fact that lime occupied a definite place in improving the physical properties of soils. However, generally speaking, the wheat-growing lands of South Australia are well supplied with this material. As a rule, the greatest loss of lime occurs where there is high annual rainfall and free drainage, with the result that, except for a relatively small area of red boggy land in the Lower North, the greatest need for lime in this State occurs in the sour soils of the Adelaide Hills and South-East. In such circumstances, dressings of at least half and preferably 1 ton to the acre are necessary, and these should be added to the land about once in every ten years.

For suburban gardeners, who are troubled by the heavy nature of the land with which they have to deal, an application of about 1lb. of lime to the square yard is recommended.

In this connection, as ground shell consists of hard water-worn fragments of calcium carbonate, which are not readily dissolved by soil moisture, other forms of agricultural lime of a more soluble nature are to be preferred.

In conclusion, therefore, whilst lime has a certain value for improving soil conditions, the experiments show that it is not required as a fertiliser for cereal crops in South Australia.

In the following table the experiments from which the results quoted were obtained are shown.

Experimenter.	No Manure.		1cwt. Carb. Lime.		1cwt. Super.		1cwt. Super., 1cwt. Carb. Lime.

PAPERS READ AT CONFERENCES.

EYRE'S PENINSULA (CENTRAL), 18th October, 1935.

SOME ASPECTS IN THE BULK HANDLING OF WHEAT.

[C. JOHNS, Wudinna.]

In this paper it is intended to state briefly the more familiar advantages of Bulk Handling. They are as follows:—

1. The saving in cost of bags variously estimated at from 4 to 10 per cent. of present purchases, and the bags should last four seasons. There is considerable difference of opinion regarding this item, as must necessarily be the case when different methods of harvesting, cartage, distance, &c., are taken into consideration.
2. The wheat would be handled more quickly and cheaply.
3. Railway trucks would be handled more economically, less delay occurring in loading and emptying.
4. Losses which now occur in storage under the bag system, due to weevil, mice and climate, would be prevented.

ITS ADVANTAGES.

There are other advantages worth discussing more fully. For instance, it should be possible for the farmer to obtain a better price for his wheat by the adoption of grading, which would be possible with Bulk Handling. The f.a.q. system is not satisfactory, nevertheles it is the only system open to farmers so long as wheat is handled in bags. The f.a.q. system never gives the farmer the benefit of the doubt; the standard is always set low enough to be safe. It is distrusted by farmers. If a farmer's grain is below standard he may pass it through as f.a.q. because the merchant is also receiving wheat above the ruling standard. The farmer selling the better product gets no more, in fact, he is penalised for growing the best. During the 1933-34 harvest, wheat in many parts of Eyre's Peninsula was light. All buyers decided only to receive wheat on a 58lbs. basis, which resulted in every farmer in the district affected being docked 2d. a bushel, irrespective of the 60lbs. standard. As probably 50 per cent. of the wheat was up to standard, this was a glaring injustice, which was shared not only by the farmers, but by many agents. When the f.a.q. is set lower than it should be (and this is easily possible) it is also lower in England and there is resultant loss to the farmer and incidentally to the State. In England buyers are known to take little notice of the f.a.q. set by the different States in the way of differentiating between them, and invariably buy on the basis of the lowest f.a.q. Therefore, one State may be penalised for the misfortune of another.

There is no inducement whatever to grow a good sample and clean it as it should be cleaned. With Bulk Handling, many farmers would not recognise their own wheat as it poured out of the bags into the elevator, yet such an experience is necessary to many. The farmer cannot altogether be blamed for the chaff and dirt in the wheat as he knows he gets no more for cleaning it properly. How many farmers are satisfied with the merchants so-called "Free Storage"? There is no such thing as free storage; expenses incurred in storage are met by the farmer ultimately. The Verco Bros. case, fought out in the law courts, showed that once the wheat goes over the scales it is virtually sold. Free wheat in New South Wales—where Bulk Handling has been adopted—fetches 3½d. per bushel more than similar wheat in South Australia. Much of this extra 3½d. is attributable to the wheat being "free." A publicly owned Bulk Handling plant would ring the death knell of the famous "honourable understanding."

Consider the weighing of the bags; how many split pounds are received on a load of wheat? A weighbridge would not only be fairer, but quicker. Another point in favour of Bulk Handling is that appreciation in the weght of wheat—known to occur during storage—could, in a publicly owned plant, be put to offset construction costs. The farmer also rightly objects to maintaining so many country agencies, which are doubtless a charge against his wheat. The farmer is bound to store his wheat at some seasons, and so is relying on the mercy of the merchants. With a bulk storage unit at the siding or at a reasonable distance, independently operated, he would receive a certificate of weight, which could be made negotiable and so he could sell at will with unlimited competition from buyers in the city and elsewhere; he could also take advantage of millers' offers.

AND DISADVANTAGES.

First, there would be the expense to the farmer of converting his wagon or truck should he so decide. Rail trucks and ships would need alteration. This alteration regarding ships is now a somewhat out-of-date argument, as shippers prefer Bulk Handling, and in New South Wales bulk wheat costs 2s. 6d. per ton less for freight than bagged wheat, and shippers have stated that they will make a reduction of 5s. per ton when all Australian wheat is handled in bulk. The two most weighty arguments against Bulk Handling is first the displacement of labour. Machine handling of products —perhaps the greatest cause of unemployment to-day—seems inevitable, yet it must not be forgotten that the large amount of money now going to India for cornsacks would, if saved by the farmer, be spent on his farm, and thus give more employment.

The second sound argument is that South Australia is geographically unsuited to Buly Handling, having nine deep seaports and some 35 to 40 small ports. Besides the above, there is the hostility of the merchants who, under the present system, can easily obtain a monopoly of the supplies and so manipulate prices. The same thing would also happen with Bulk Handling were all buyers allowed to construct and own their own Bulk Handling plants at stations and sidings. In Canada and America, where this was allowed, it resulted in much confusion and necessitated considerable legislation to protect the farmer. However, this is not likely to be allowed here, because of State-owned railways and harbours. In New South Wales the Bulk Handling plant was installed by the Government at very great expense and came in for much criticism when constructed, yet, in spite of the handicap of high capital costs, farmers benefit to the extent of 2¾d. a bushel. A charge of 2d. a bushel is made for the handling, which includes interest on the cost of installation.

THE WESTERN AUSTRALIAN SCHEME.

In Western Australia a scheme of Bulk Handling of wheat is operated by a limited company, The Co-operative Bulk Handling Co., Ltd. This concern operates at 53 sidings and took over the sites, sheds, plant, &c., of Westralian Farmers Ltd. and the Wheat Pool of that State. Bulk Handling Ltd. is run by those two concerns and two others. They enjoy something in the nature of a monopoly, and for this reason had to fight hard to obtain the necessary concessions from Western Australian railways. The agreement entered into between Bulk Handling Ltd. and the growers who use their facilities is as follows: The company is to make a reasonable charge for handling and will arrange with growers to advance to the company amounts per bushel called "tolls" to be used by the company to recoup them for original outlay and the repayment of purchase-money, advances and interest. The farmers eventually shall become the sole owners. They will pay a toll of ¾d. per bushel on wheat delivered until such time as the costs are paid. The whole capital cost of the system was less than £150,000. Handling costs amount to 1½d. per bushel, and the net saving to the grower is 2½d. per bushel compared with 2¾d. in New South Wales. A Royal Commission, inquiring into Bulk Handling in Western Australia, in its report recommended that Bulk Handling Ltd. be allowed to complete its proposal for a State-wide scheme and the provision of up-to-date orthodox concrete terminal silos at Fremantle and Geraldton, controlled by the Harbours Trust and railways respectively. The Commission also considered that legislation should be enacted for the protection of those vitally interested in

Bulk Handling, which suggests that the farmer under the scheme now operating is not sufficiently protected against losses which might occur. Both of these two methods —that of New South Wales (State-owned) and that of Western Australia (co-operatively-owned)—have much to recommend them. The State-owned does not necessitate the farmers having to raise the large sum of money required to commence operations, and they should have a means of appeal against hardships, losses and any other injustices which might occur in starting operations. Such an appeal would perhaps not be available if the concern was owned privately.

The latest inquiry into Bulk Handling in South Australia was that of the Public Works Standing Committee, who issued its first report in 1933. Evidence taken in New South Wales and Western Australia strongly favoured Bulk Handling. The scheme advocated by the above Committee was that an experimental unorthodox system be started at Wallaroo with a later extension to Port Adelaide. A cost of 3d. per bushel on export wheat and 2½d. on local consumption wheat was stated to be necessary to meet handling costs; the farmers using Wallaroo and Port Adelaide facilities were expected to benefit to the extent of £146,000, and the Government would profit to the extent of £17,600 in a normal season. The Public Works Committee suggests that the scheme be controlled by a Board of Management of one representative each of the following:—Government, Harbors, railways, merchants and farmers.

These three schemes are much in the limelight at present, and it is likely that at last something may be accomplished. If all farmers seriously consider the possibilities of Bulk Handling they will come to the conclusionthat it is a means of substantially reducing costs of production and an economy which cannot much longer be denied. A few pence gained per bushel on our wheat means, not only a great saving to the farmer, but to the State also. Can we afford to overlook up-to-date methods when economy in every direction is so urgent and competition so keen?

MANAGEMENT OF THE FARM FLOCK.

[Max O'Brien, Kyancutta.]

Owing to the high cost of production and the low price obtained for wheat during the last few years, many hard working men have left their holdings in the Mallee areas. This action is very detrimental to South Australia, for it not only means that there is another man joining the ranks of the unemployed, but in most cases it means that there is another partly developed farm going out of production. Though it may be said that the State is producing more wheat at the present time than can be sold at a profitable price, the fact remains that by such lands going out of production a further burden is placed upon the man who is still willing to carry on and try to pay his way under present conditions.

Therefore, an effort must be made to suggest some way to enable every mallee farmer to obtain a living from his holding, and there is no better way at present than by turning his attention to sidelines. Owing to distance from markets it is impossible to make more than a small profit from pigs, butter or eggs. These lines, of course, will bring in a few shillings per week to the average farmer, which in these days is a great help, but they will not help him to pay rates, taxes and working expenses on his farm. To meet these commitments there is no better way than the raising of stock and the production of wool.

Sheep and Wool.

It is not meant that the farmer should give up wheat growing and depend on sheep for a living, but that he should combine the two and get the maximum return from his holding.

The first point to consider is whether the farmer is to produce export lambs or rely entirely upon wool for his returns.

If for wool alone, a good type of plain-bodied Merino ewe should be selected and mated with a robust, large-framed Merino ram. The selection of the ram is all important. He must be free, so far as possible, from wrinkles, and show masculine quality with a good, dense fleece of strong wool. A broad forehead with horns set well apart is another essential feature. Much useful information can be obtained by members attending agricultural shows and getting the judges to outline the good and bad points of the exhibits after the awards have been made. Should the farmer consider the production of lambs for export, he would be wise to obtain big, roomy Merino ewes, which have been previously mated with Merino rams, and cross them with an English ram—one of the British breeds suitable to his district. I would suggest the Dorset Horn ram as a sire for mating with Merino ewes, the result being a well-formed, quick-maturing lamb. The Merino ewe gives a greater return from wool than any crossbred ewe, although the crossbred ewe produces a slightly better lamb for export than the Merino, chiefly because she is a better mother. If using a Dorset Horn ram, be careful to select ewes which have had a lamb, as many young ewes are lost through being mated with these rams.

The next item to decide is the number of sheep that can be carried safely. Do not risk overstocking, as this may ultimately defeat the original purpose. It is not only the number of sheep lost through overstocking that counts, but the number of lambs as well. Again, overstocking is likely to cause drift, which causes sand and dust in the wool, thereby reducing its value. A sheep in poor condition will not give the same return as one which has been in good order the whole of the year.

In order to avoid the possibility of losing sheep and at the same time obtain the maximum return by carrying as many sheep as possible, provide a reserve by planting cereals for feed, the planting of suitable grasses such as Wimmera Rye Grass and Lucerne, or by top dressing present pastures.

Sheep are also a great asset in keeping fallows free from weeds and returning a big percentage of manure to the ground, but they should not be used excessively as scavengers as it is most detrimental to the wool.

SHOULD THE SYSTEM OF FARMING, AS PRACTISED IN THIS DISTRICT, BE REVISED?

[E. H. Edmonds, Pygery.]

The cultivation of the soil for the production of food supplies for mankind, can be traced back to the dawn of history. Bounteous Nature supplied the wants of primitive man, in the form of seeds, roots, herbs, &c., but it is believed that even in those distant ages the discovery was made that cultivation and tillage of the soil improved both the quantity and quality of its products.

The early Egyptians are credited with having introduced agriculture on a large scale. Even before foreign conquerors had entered that land, methods of agriculture had been evolved to suit the peculiar conditions of the Nile Valley, and so it has continued, ever changing conditions have called for altered and advancing ideas.

As man set out on his mission to "replenish the earth and subdue it" the changing of economic conditions, again gave rise to an alteration in agricultural practices. He became, not only a grower of his own requirements, but also the requirements of those engaged in other pursuits, and systems of barter and exchange were introduced.

The discoverers of Australia, indeed, even our pioneering forefathers, found a primitive man inhabiting this vast Continent, who depended entirely upon Nature to supply his daily bread and means of subsistence, but the white settlers' needs were greater, and in consequence, old world methods were introduced for assisting Nature to supply the demand. It was not long before the newcomers discovered that this country presented agricultural problems peculiar to itself and with which they were unfamiliar, but as development extended such problems were met and dealt with.

With a steady increase in the country's population, agricultural and pastoral activities were extended further out beyond the main centres of settlement, and as such extension took place, so the problems incidental to changing climatic and soil conditions increased. It was soon realised that rainfall became less as advance was made inland away from the coastal areas. This was met by the introduction of a system of fallowing, and by keeping the surface soils loose and friable, thus aiding the conservation of moisture taken into the ground during the fallow period and having it available for the subsequent sown crop. It was found also that disease attacked the crops, especially wheat, but certain varieties were discovered and established that were resistant or immune to such diseases. Further, varieties of cereals were introduced having a shorter growing period and which more quickly reached maturity. Later on it was found that the scrub or mallee lands were capable of being converted into good farming areas, and implements were devised and invented for dealing with this particular class of country, and thus development went on until the present time.

Throughout the years covering the history of agricultural development, problems have arisen that must be solved, and difficulties crop up which must be overcome, and it is safe to say that history will go on in repetition of this state of affairs, and it is our job as men engaged in the business to play our part in meeting the position as we find it.

THE SETTLEMENT OF THE DISTRICT.

In common with all mallee areas the first job was to clear the scrub. Sheep and other stock had to be carried, both as a source of revenue and for assisting in building up the fertility of the soil. Fencing, water supplies, and the many other improvements and facilities had to be provided, and as these were established, farmers settled down to a more or less orthodox system of agriculture, in which bare fallowing—and at least some introduction of rotation of cropping—played an important part. However, it must be admitted that the continued recurrence of problems is just as much in evidence to-day as in the past, and it is this fact that gives rise to a consideration of the matter as outlined in the title of this paper.

It is quite safe to say that the ultimate aim of farming methods is to procure a maximum return for a minimum outlay. Farming is a business, and because certain practices have been followed over long periods of years, and have become to be recognised as something in the nature of a standard, there is no reason why some departure from established usages and customs should not be attempted, if such change is considered advisable to meet altered conditions.

As followers of agricultural pursuits, residents of this district have suffered—in common with those engaged in the industry elsewhere—on account of the unsatisfactory economic conditions that have prevailed for a number of years. In addition, farmers in this part of the State have to contend with a comparatively low rainfall and land of light texture.

The orthodox system of recognised good farming methods includes a rotation of bare fallowing, but farmers in this district must very seriously consider whether this practice can be longer followed, and whether some other method will be necessary, giving a better economic result.

FALLOWING.

Its Advantages.

1. The advantages of bare fallowing.
2. The disadvantages of same.
3. A suggested alternative and its relation to 1 and 2.

The term or word "fallow" means "untilled" or "ploughed and left unsown." This practice was carried out long before this Continent was discovered or at least inhabited by white people, but it appears that this method was used by the ancient farmer as a means of resting his land and allowing it to recuperate by the absorption of fresh supplies of plant food gathered from the air and rendered available through chemical action, following the entry of light and aeration of the frequently worked upper layers of the soil.

The Australian farmer of to-day recognises thc beneficial results following the practice of bare fallowing, but undoubtedly it is the claim for a better conservation of moisture that provides the greatest incentive for its general practice, particularly in areas of lower rainfall.

From a purely district standpoint, it can be added as advantages of bare fallowing, that the heavier work of ploughing and picking off stumps and stones is more conveniently done during the fallowing season. The land is then in a well worked state and can be seeded in less time and fuller advantage can be taken of favourable seasonal conditions. Weed growth—if kept under control on the fallows during spring and summer—is more easily dealt with and cleaner crops are the result. Bare fallow is also an undoubted preventive. Takeall and "Haydie," due principally to the fact that all growth of grasses, &c., that are susceptible to attack are eradicated.

Crops cleaner and truer to type can be grown on fallowed land owing to the absence of self-sown growth, and in many other directions this old established practice has other advantages that are known and appreciated by farmers generally.

THE DISADVANTAGES.

The first, and by far the greatest of these, is the tendency of the light-textured soils—such as are found in this district—to blow and drift.

After 20 years residence in the district it must be admitted that as the scrub is cleared out the natural wind-break is removed, and in consequence strong winds have full play over the cultivated areas, with the result that the loose surface soils are blown away together with vegetable matter and humus that have taken years to put there. Every farmer in this district has had the experience of going on to a paddock of bare fallow at seeding time and finding acres of it hard and bare and the loose top soils piled up along the fences, or on adjacent roadsides.

Some farmers contend that the drifting of the sandridges out to the intervening flats tends to improve the quality of the latter, and the writer has to admit at one time subscribing to this opinion, but this has disadvantages, inasmuch as the ridges become blown out into uneven holes and hillocks, right down to the underlying clay and limestone, and thus become of poor quality from a cereal growing point of view; much of the land hereabouts consists of "sand ridges" as distinct from "sand hills," and by the provision of humus from animal droppings and the growth of suitable clovers, &c.; these can and are being built up into quite good soils. It seems to be definitely uneconomic to make it possible for this to be blown away in the matter of a few days of rough windy weather.

A further disadvantage is the loss of feed from the area fallowed for at least half the year. Where sheep are kept these are run on the area for the purpose of keeping down any weed growth that appears, and the travelling of such stock over the ploughed ground acts as a cultivation and tends to keep the surface soils loose and friable. Farm wool is notoriously dirty for this very reason, and therefore sheep running on fallows never produce a clean fleece. A difference of at least 2d. per pound will result between dirty and clean wool of the same relative quality, and in the average farm flock this may mean anything up to, say, £40 per annum that will need to be offset by an increased yield of the resulting crop grown on fallowed land.

Having briefly examined the pros and cons of our present system, let us pass on to a consideration of the possibilities of achieving our object of procuring a maximum return for a minimum outlay, by some other methods more suitable to our time and needs and the physical peculiarities of this class of country.

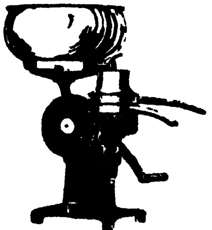
SEPARATOR
THE
"ALFA LAVAL"



Holds the
World's
Record
for Clean
Skimming

Rustless Metal Bowl and Discs.

AWARDED FIRST PRIZE!
Royal Agricultural Society's Show, 1935.

Allowance made for old Separator, and balance on easy terms.

A. W. SANDFORD & Co.,
Limited,
Grenfell Street, Adelaide.

It is to the interest of every Farmer to belong to the AGRICULTURAL BUREAU.

Join the nearest Branch, or if you are not within driving distance of the nearest branch write to the General Secretary, Central Agricultural Bureau, for particulars as to how to form a Branch.

WOMEN interested in Agriculture should join a Woman's Branch. Full particulars on application.

ESA BLUESTONE
MANUFACTURED BY
THE ELECTROLYTIC REFINING AND SMELTING COMPANY OF AUSTRALIA LIMITED, PORT KEMBLA, N.S.W.
Guaranteed to contain not less than 99% Sulphate of Copper.

USE IT— In preparation of Spray Mixtures for Fruit Trees and Vines.
For Treatment of Foot-rot in Sheep. For Wheat Pickling.

Agents for all States:
ELDER SMITH & Co., Limited. All Capital Cities.
Write for Booklet—"Better Yields by Spraying with ESA Bluestone."

[*Papers Read at Conferences.*]

THE ALTERNATIVE.

Sheep and Wool.

Ninety-nine per cent. of farmers will declare that to produce a satisfactory return from wheat, crops must be sown on fallow, and there is ample evidence available to support this contention, but the point for consideration is, can similar objects be obtained by other means, without the disadvantages that have been enumerated? By similar results, is meant the ultimate monetary return from the farmer's outlay in capital, time, and labour.

In recent years farmers to some extent have ceased to "place all their eggs in one basket" by depending entirely on wheat growing. The keeping of sheep for wool, the raising of lambs for export, production of pigs, and in some cases dairying, have given more or less revenue from sidelines, but we can, with advantage, increase the number of stock and give attention to the growing of other cereals, and make them a source of revenue production to an extent that will leave us free to regard the matter of wheat growing of lesser importance than it is to-day.

Despite the somewhat chaotic economic conditions prevailing in the world and their influence on the question of the disposal of primary products, it appears that wool is a commodity that at all times commands a fair average price. Australia is one of the greatest producers, and further, produces a class of wool required for almost universal needs.

WATER AND FODDER SUPPLIES.

The first requirements for a flock of sheep are an abundance of water and feed. In this district, the former is provided by the Tod River scheme, and as there does not appear any likelihood of the mains being extended to an extent threatening the present supply, this can be taken as being assured.

The question of food, however, is of real importance and requires careful planning and forethought. Two hundred sheep in good condition with an abundance of feed are of more value than 400 half starved, bony wrecks, so that if flocks are to be increased steps must be taken to provide adequate food supplies, not only for immediate use, but against those lean periods that experience has taught us periodically occur. The natural grasses and weed growths that follow cropping will not do this, and the conservation of fodder crops for this purpose becomes necessary.

Having regard first to the somewhat doubtful rainfall, and second, to the growing of that class of crop that is going to assist in building up the soil fertility, oats are placed first as being most suitable. In an average year oats will stand grazing for a while during the growing period, can later be reaped for grain and stored as a reserve to be hand-fed during autumn and early winter, should natural paddock feed be scarce at the seasons mentioned. Provided some care is taken at harvest time and the oat heaps are made long and narrow and well covered with straw, there is no need for these to be winnowed. In due time, the heaps can be fed to sheep as required, chaff and all, in feeders or distributed in the paddocks on the ground. By this means, the cost of cleaning and bags can be saved, and the loss owing to the ravages of mice—which usually takes place where oats are stacked in bags—is eliminated.

Barley grows well in these districts, in an average season, and whilst the writer has no personal knowledge of its use as a sheep feed when fed as grain, it provides a good early green fodder crop and the corn is good food for pigs. In addition, the malting varieties should be grown for sale, taking the place of wheat and worked in a system of crop rotation.

There is no reason why profitable crops of this cereal should not be grown here, at least in seasons of average rainfall.

South Australian malting barley has a good reputation, not only in the home market but abroad, and much of this State's output is produced on Yorke Peninsula and from country very similar to this district.

PIGS AND COWS.

The breeding of pigs for supplying the export and home markets also presents a source of revenue. Fodders and corn can be grown that, marketed through livestock, will give a better return per acre from the area utilised, than will be yielded by the average wheat crop at present prices.

For those conveniently situated to a siding, the return from cows can be made quite satisfactory, but here again ample provision must be made for fodder supplies. Dairy cows require good succulent food, and whilst this is available during winter and spring by natural grasses or planted crops, it is best provided during summer in the form of ensilage. The writer has no personal experience of the preparation or use of this class of fodder, but from information available, and the fact that those people engaged in the industry conserve supplies and grow crops especially for this purpose, its beneficial results are undoubtedly established.

There is now upon the market a grade of artificial fertiliser for which the makers claim special advantages where it is used in the production of crops off stubble and grass lands. This appears to be one of those instances of which mention was made earlier where steps are being taken to meet altered conditions, and this should be given a trial as a means of working a rotation of cropping combined with other farming activities, that will permit of the elimination of bare fallowing, but still achieve the same or even better economical result.

The application of heavier dressings of superphosphate and the application of other forms of artificial manure tends to the establishment of other and better classes of fodder crops and grasses, such as clovers, and these in turn increase the carrying capacity of the land and at the same time enrich the soil.

As a suggested rotation, cutting out bare fallowing, it should be possible to work the following, viz.:—Wheat, oats, barley, oats, grazing, wheat. As barley and wheat are both subject to Takeall, it would appear to be advisable to break these two with a crop of oats, and by having oats following barley and then grazing, there would be little danger of barley appearing in the wheat crop to follow.

The barley crops can either be malting or feed lines. The former should find a market at a satisfactory price, whilst the latter can be fed to stock. The harvesting of Malting Barley requires more care and attention than is necessary for other cereals, but information on this point is readily available, and no doubt farmers could and would soon become conversant with the points mentioned.

To summarise:—

Revise the system of farming in this district by the elimination of "bare fallowing."

Increase the carrying capacity of the land by:—

(1) The planting and establishing of better classes of grasses and fodders.

(2) Growing cereals for feeding to stock, particularly oats for sheep and barley for pigs.

(3) Reduce the area under wheat and increase the number of sheep and other livestock carried on the farm.

TREATMENT OF FALLOW.

[O. J. MURPHY, Warramboo.]

Statistics show that the wheat yield in South Australia on fallowed land is considerably higher than the yield of non-fallowed land. It is to be regretted that so far as Eyre's Peninsula is concerned, a comparatively small percentage of the crop is sown on bare fallow. If the Eyre's Peninsula farmer had sufficient confidence in the practice of fallow to give to it the same amount of earnest endeavour as he gives to seeding and harvesting operations, the improvement in the general average wheat yield would be outstanding.

The main objects of fallowing should be the conservation of moisture, the destruction of weeds and the formation of a solid seedbed. The seedbed in which the wheat plant thrives best is a well compacted soil overlaid by a shallow layer of fine loose soil.

In the upper part of Eyre's Peninsula, farmers have to deal with sandy and light loamy soils over porous limestone subsoils—in which the mallee stumps have yet to be totally destroyed. Obviously the formation of a solid seedbed is a difficult problem. Moreover, it is necessary to contend with weather conditions which are frequently very severe in spring. The failure to appreciate the importance and the difficulty in obtaining the kind of seedbed the wheat plant requires, is probably the chief reason why fallowing is not more widely practised, and also the reason why fallowing has so frequently led to disappointing results. The neglect of taking at least some measures to guard against adverse weather conditions in spring may also be a contributing factor towards disappointing crop returns.

Rain is an important agent in the forming of a compact seedbed, and where the rainfall is light, fallowing should be done early—immediately after seeding. A stroke of the harrows soon after the first working of the soil is of great advantage, particularly if the soil is well grassed. This operation appears to be of more importance than the cultivation of the land in spring. Spring months are often marked by dust, periods of dry weather, high temperatures and hot winds; conditions which are not suitable in working up soils liable to drift. Spring cultivation should be done if possible when the surface of the soil is damp.

The management of fallow in the late summer, and autumn and seeding periods often determines the success or failure of the crop, irrespective of the character of previous workings. Deep working of the fallow during these latter periods should be avoided. Use harrows in preference to the cultivator, and disc drill in preference to the combine wherever soil conditions permit. Harrows will destroy 90 per cent. or more of the weeds if used immediately after germination, and if loose stumps, roots, and other obstacles are first removed, harrows with share points attached will ensure a first class job. A 100 per cent. job cannot be expected while there are stumps in the soil to lift the cultivating implement when the wheels pass over them. The point to be emphasised, however, is that though shallow cultivation may not destroy so many weeds, the weeds not destroyed will not affect adversely the crop yield to the same extent as deep cultivation, resulting in the loosening of the seedbed. In the writer's experience, the use of a cultivator at seeding time to destroy Mustard plants resulted in a decrease of at least 30 per cent. in the wheat yield as against the use of drill and harrows on fallow in the same paddock.

In regard to spring fallow, it is doubtful whether spring fallow pays under local conditions. In years of low rainfall and scarcity of early winter feed, farmers are tempted to postpone fallowing operations until spring, when the feed will have reached its fullest growth.

As the use of rollers or cultipackers is impracticable on light, stumpy ground, it is impossible to obtain a good seedbed after turning in feed in spring. Better crop results will probably be obtained by burning off the grass in February and then cultivating the soil in preparation for seeding. A course of action likely to give good results is as follows:—Before fallowing immediately after seeding—and if the soil is light—use the rigid tine cultivator in preference to a disc or mouldboard plough, in order to leave rubbish on the surface. Complete the initial working by the end of July. Harrow the soil as it is ploughed. This will mean an average of one day's harrowing per week. Use the cultivator with wide shares, working at a shallow depth in spring, preferably when the surface is damp. In late summer and autumn, have the harrows ready for use after rains which may germinate weeds. If conditions have been favourable for the early germination and destruction of weeds, use a drill and harrows in preference to a combine, and sow during May. If no early rain and germination of weeds have taken place, sow in May just the same, and use the harrows three or four days after the first good rain has fallen. Crops sown on fallow during May in an average season will not be damaged by frost, and will also be sufficiently far advanced to withstand adverse weather conditions in spring.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April, 1935, to 31st January, 1936.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 31st December, 1935.	No. Eggs Laid Month of January, 1936.	Total Eggs Laid 1st April, 1935, to 31st January, 1936.
No. 1 Test	5,508	675	6,183
No. 2 Test	5,713	734	6,447

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on 29th January, there being present Hon. A. L. McEwin, M.L.C. (Chairman), Messrs. A. M. Dawkins, H. N. Wicks, F. Coleman, S. Shepherd, P. J. Baily, A. J. A. Koch, G. Jeffrey, Prof. A. J. Perkins (Director of Agriculture), Dr. A. E. V. Richardson (Director, Waite Research Institute), and H. C. Pritchard (Secretary). Apologies were received from Messrs. J. W. Sandford, J. B. Murdoch, and A. J. Cooke.

Life Members.—In recognition of 20 years' association with the Agricultural Bureau, the names of Messrs. A. T. Cowley (Roberts and Verran) and L. J. Cook (Kybybolite) were added to the roll of Life Members of the Agricultural Bureau.

New Branches.—Approval was given for the formation of a Women's Branch of the Agricultural Bureau at Georgetown with the following ladies as foundation members:—Mesdames J. Lyons, W. Sanders, V. Todd, R. Treasure, M. McAuley, J. Noonan, G., P., and D. Smallacombe, C. Wilkins, W. McNamara, T. M. Wyatt, J. Carmody, W. Odgers, E. Buckenara, J. Bond, A. Crawford, Misses N. & J. Crawford, L. Noonan, K. Bond, E. McAuley, R. and M. Ingles, I. Wilkins, K. Miller, D. Smallacombe, D. McNamara, M. Higgins (2), C. Carmody, C. Odgers, T. Buckenara, M. Phillis.

New Members.—The following names were added to the rolls of existing Branches:—Adelaide—H. Fairbank, N. P. Hele, F. Shaw, D. J. Chancellor, D. J. Millard, H. O. Rogers, A. E. Baker; Balhannah—W. W. Miller, E. H. Schmidtke, L. Nagel, A. Nagel, S. Petersen; Balumbah Women's—Mrs. F. M. Clements; Belalie Women's—Mrs. R. Goldsack; Black Springs—Reg. Heinrich, John Heinrich; Boor's Plains—Ken. Vidal; Buchanan—Fredk. C. Reichelt, Wm. J. Holding; Bute—J. H. E. Purdie, R. W. Langman, W. N. Trengove, C. Measday, A. Sawley; Butler—B. D. Teakle, Rex B. Teakle; Collie—E. C. Shipard, W. Shipard, R. L. Dolphin, T. G. Dolphin; Coonawarra—Leonard Clayfield, E. A. Childs, Chas. Soper, H. N. Brown, D. N. McGillivray, N. J. McBain, Miles Geraghty (jun.); Coonawarra Women's—Mrs. Chas. Soper; Cungena—A. Taylor, W. A. White; Dudley—E. Possingham, R. K. Henderson; Frayville—A. C. Bormann, J. H. A. Wegener, C. B. Pfeiffer, G. A. Quast; Goode—J. Cooper; Goode Women's—Miss M. Lutz; Hanson—A. B. Riggs, W. S. Field, E. Phillips, H. F. Saunders, Mrs. D. G. Stevens; Hartley—L. G. Brook; Hope Forest Women's—Mrs. B. M. Dodd; Inman Valley—J. M. Westlake, G. Newberry; Jervois—H. H. Jenico, A. O. Janico, N. Anjou, W. Gregory; Kilkerran—V. Glasohm; Koppio—C. Cooper, F. Whittaker, E. Wait; Kybybolite—R. Hutchins, O. W. Corbin; Kybybolite Women's—Mrs. D. H. Irving; Longwood—E. W. Pfenning; McLaren Flat—Fordo Trott, Ronald Ward, F. B. Wilson, Ron. G. Nottage, E. M. Elsworthy, L. A. Preedy, F. Holm, F. K. Smith, A. J. Whiting, J. Dowdell; Milang—J. McCarthy; Millicent Women's—Miss Yvonne Varcoe; Monarto South Women's—Mrs. A. H. Schubert, Miss M. Stevens, Miss R. Hartmann; Morchard Women's—Mrs. C. Koch, Miss M. Koch; Mount Barker—J. Lucie, F. Spicer; Myponga — — Bounds, — Thomas; Sheoak Log Women's—Mrs. — Schwartz; Springton—V. H. Mueller; Strathalbyn—Harold J. Stowe, Les. Halls; Tatiara—L. J. Young, E. Fridd, R. Fridd, W. Fridd, R. C. Allen, D. J. O'Liffe, R. W. R. Hunt, A. A. Pitcher; Warramboo—E. Adams, W. W. Adams; Wasleys Women's—Miss E. Fagg; Wepowie—Harold Wm. Symes, Eric J. Martin, E. P. Yeatman, L. H. Pascoe; Wepowie Women's—Mrs. L. Pascoe, Miss S. Gregurke, Mrs. J. Crocker, Mrs. A. M. Ware; Williamstown—N. V. Wilson, Joe. Buckley, Clarence Vinall; Wirrabara Women's—Mrs. H. H. T. McLean, Mrs. D. Deer, Mrs. C. Hollit, Miss Grace Horner.

Barley.—The following advice was received from the Comptroller-General of Customs in reply to a request for information concerning trade arrangements with Belgium in relation to the export of barley:—"The provisional Trade Agreement concluded on 19th November, 1934, by the Governments of Australia and Belgium is still in force and, under the terms of the Agreement, is subject to denunciation on two months' notice by either party." Received.

Noxious Weeds.—At the October meeting the Board forwarded a resolution to the Hon. Minister suggesting that the eradication of noxious weeds afforded an opportunity to give valuable work to unemployed. This was referred by the Minister to the Noxious Weeds Committee, and the Chairman replied as follows:—"Consideration was given to the resolution of the Advisory Board of Agriculture, and the Committee decided to recommend to the Minister that a reply should be sent to the Advisory Board that the Committee considered that to enable any great advance to be made in the eradication of noxious weeds throughout the State, it is essential that public opinion, which is at present apathetic, should be aroused to the necessity of coping with the problem, and that in this regard the local Branches of the Agricultural Bureau could render very valuable service." It was decided that the Secretary should suggest to Branches of the Bureau that the reply from the Noxious Weeds Committee be brought under the notice of local District Councils.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SUMMER, 1936.

Eggs for Hatching and Day Old Chickens

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.

DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

BLACK ORPINGTONS.

EGGS.—10s. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—17s. 6d. per dozen ; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.

DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

Free on Rail, Salisbury. DELIVERY.—CHICKS—January to March.
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2oz., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

Dentists Visiting Country Schools.—In response to a Congress resolution asking that the Government consider sending a dentist to country schools at least one visit annually, the Director of Education reported to the Minister that the Department had two dentists and two dental assistants, that the children of certain schools had been treated during the past 18 months, and that most of the work had been done in the country. He added that his Department was unaware of any State in which all the country schools were visited by a Government dentist each year. With the present staff, it was impracticable to consider the request of Congress. (The schools referred to are Springton, hundred of Jutland, Kenton Valley, Gumeracha, Forreston, Cromer, Birdwood High, Charleston, Mount Torrens, Harrogate, Murdoch's Hill, Littlehampton, Wistow, Mount Barker High, Mount Barker Probationary, Boolgun, Holder Siding, Kanni West, Murray View, Maggea, Taylorville, New Well, Holder, Ramco, Loveday, Wattle Flat, Inman Valley, Torrens Vale, Myponga, Delamere, Hindmarsh Tiers, Hope Forest, Mount Compass, Sellick's Hill, Aldinga, Yundi, Honiton, Coobowie, Lake Sunday, Sunbury, Oaklands, Pickering, Moorowie, Brentwood, Rocky Beach, Minlacowie South, Weavers, Bublacowie, Cranbrook, Mount Rat, Roolama, Raeburn.) It was decided that the reply from the Director of Education should be published in the *Journal of Agriculture.*

Yard Fees at Country Markets.—The Secretary of the South Australian Stocksalesmen's Association intimated that the request to review the yard fees at country markets had been discussed by his Association, and it was agreed to adhere to the present arrangements. The advice was received.

Sheep Dipping.—In reply to the request of the Yeelanna Conference the Minister informed the Board that approval had been given to the appointment of Mr. N. V. Sedunary as an Inspector of Stock at Port Lincoln. Mr. Sedunary would, among other duties, take the necessary action for the control of lice and tick in sheep, and enforce the provisions of the Brands Act, 1923.

Instructor for Murray Swamp Areas.—The Secretary reported that applications had been called for an Agricultural Instructor for the reclaimed Murray Swamp Lands.

Rust in Wheat.—The Ungarra Branch submitted the following resolution:—"That the Department be urged to concentrate on fighting the rust menace as a vital step in the all-round improvement of our wheat." Professor Perkins stated that the problem of rust in wheat was being investigated scientifically by the New South Wales Department of Agriculture, and that one could not expect such work to be duplicated in each State. Dr. Richardson said the breeding of rust-resisting varieties of wheat was part of the programme of the work being done by the Wheat Improvement Committee in South Australia, which was established by the Minister. The Secretary was instructed to advise the Branch in terms of the above statements.

Young People's Employment Council.—The Secretary read a report, for the information of the Board, of the Conference held in November.

Non-irrigated Fruitgrowing Districts Conference.—The Greenock Branch offered to sponsor the next Conference of Branches in the non-irrigated districts. (At the Conference held in November none of the branches offered to hold next year's Conference.) The Board accepted the offer of the Greenock Branch.

Next Meeting of the Board.—It was decided that the February meeting of the Board should be held at the Blackwood Orchard.

Several items were taken in Committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & Co., LIMITED, reported on 1st February, 1935:—

BUTTER.—The production of butter in South Australia has been gradually declining for many weeks past, and there is not now sufficient choicest being manufactured in this State to meet the current demands for print butter. Consequently, importations from Victoria are now necessary. On the other hand, there is a surplus each week of lower grades which must be packed for overseas. Under the equalisation plan rates in the local market have remained unchanged, although farmers have had advanced prices paid for butterfat. The London market has improved in values during the last week, but, unfortunately, the quantities to go forward to meet the favourable market are only small. Present local rates are:—Choicest creamery fresh butter in bulk, 1s. 3¼d. per lb. Prints and delivery extra. (This price is for local sale only, and under the quota system the equalised price manufacturers will receive will be 1s. 0¾d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines from 10½d. to 11½d. per lb. for choicest; stores, 6d. to 8d. per lb. (These prices are subject to equalisation levies.)

CHEESE.—Reports from the South-Eastern factories indicate that the milk supplies are now falling back very rapidly, but this was only to be expected after the high productivity earlier in the season. Westralain buyers have resumed purchasing and local trade has been well maintained, but there is still a surplus available for export. Local prices have continued without alteration at:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. 1d. to 1s. 1½d. per lb.

EGGS.—Although supplies are lessening each week there are more than sufficient for local needs but, unfortunately, a large proportion of the eggs arriving in Adelaide during the past few weeks have been of very poor quality and not suitable for cafe or shop trade. For good quality eggs the demand has been well maintained and values firmed. Ordinary country eggs, fair average quality, from 4d. per doz. net; long distance rail or shipping eggs lower; selected new laid, clean eggs, full sized, 8½d. to 9d. per doz. net.

BACON.—During the warm spells the demand for bacon weakened, but trade generally was satisfactory all things considered. A strong demand continued for bacon factory smallgoods, and cooked hams are selling well. Rates are:—Best quality sides, 9d. to 9½d. per lb.; middles, 9½d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 1s. 0½d. to 1s. 1d.; cooked, 1s. 3d. to 1s. 3½d. per lb.; lard, bulk, 5d. to 5½d.; prints, 6d. to 6½d. per lb.

ALMONDS.—Supplies of the new crop are now coming to hand each week, although they are not very great as yet. Where the almonds were thoroughly dried out there were ready sales, and quotations are unchanged at:—Softshells and Brandis, 9d. to 9½d.; hardshells, 5¼d. to 5½d.; kernels, 1s. 10d. to 1s. 10½d. per lb.

HONEY.—Only a limited demand was experienced for honey throughout the month, and heavy quantities were carried over from week to week. The outlook for the disposal of large quantities is not very promising unless some overseas outlet can be obtained, as there seems little likelihood of it being disposed of in Australia. Rates are:—Prime quality clear extracted, 2d. to 2½d. per lb.; lower grades, 1d. to 2d. per lb.

BEESWAX.—Has been somewhat dull of sale for a few weeks, but demand is expected to improve shortly. Quotations are:—1s. 2½d. to 1s. 3½d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms, which are in every way the best equipped in the State. The markets have been fairly well supplied since Christmas, and for good quality lots prices continue satisfactory. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. 6d. to 4s. 9d.; nice-conditioned cockerels, 2s. 8d. to 3s. 5d.; fair-conditioned cockerels, 2s. to 2s. 7d.; chickens lower; heavyweight hens, 2s. to 2s. 10d.; medium hens, 1s. 6d. to 1s. 11d.; light hens, 9d. to 1s. 4d.; couple of pens of weedy sorts, lower; prime young muscovy drakes, 3s. 3d. to 4s. 6d.; young muscovy ducks, 1s. 9d. to 2s. 6d.; ordinary ducks, 1s. to 2s.; ducklings, lower; geese, 2s. to 3s. 6d.; goslings, lower; turkeys, good to prime condition, 9s. to 1s. per lb. live weight; turkeys, fair condition, 7d. to 8½d. per lb. live weight; turkeys, poor and crooked breasted, lower; pigeons, 4½d. each.

POTATOES.—New season's, 7s. per cwt.

ONIONS.—New season's, 8s. 6d. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of January, 1936, and also the average precipitation for January, and the average annual rainfall.

* No report received during the month of January. R In recess.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

DAIRYING.

Dairying as a Sideline on the Farm.

"Our Dairy Cows" was the subject of a paper read by Mr. R. Woodrup at the October meeting of the Pygery Branch. Dairying as a sideline to farming operations in this district, he said, was receiving considerably more attention than it did formerly. The cows should be chosen for their capacity as producers, then by the use of specially selected sires the standard of the herd could be raised. The treatment of the cows on the general wheat farm left much to be desired, and indiscriminate mating was a fault that should be corrected. High producing cows required plenty of good feed, a constant supply of fresh water, and adequate shelter in summer and winter. As summer approached and feed and pastures dried off the ration should be supplemented with some form of concentrates. Linseed meal and bran was a good addition to the hay chaff. Heifers should not be mated until 18 months old. At calving the calf should be left with the mother until it had taken the first milk from the cow. Feed the calf with a little new milk three times each day for a week, then twice a day until three weeks old, when separated milk can be added in increasing quantities until all separated milk is being fed. Care and patience must be exercised in breaking in the heifer, and on no account should the animal be illtreated. Small cowyards are a never ending source of trouble, because cows that are timid have not sufficient space in which to get out of the way of the more "bossy" animals, and this not infrequently results in injuries to the udder. Keep all dairy produce as clean as possible and free from contamination by flies. Separate immediately after milking, and if the cream has to be held for some days—as is the case in so many country districts of this State—it should be kept in an earthenware vessel in the coolest place on the farm. The writer also gave useful hints in the treatment of various ailments of dairy cows. The opinions expressed in the paper met with the approval of members who took part in the discussion, the consensus of opinion being that now that a market was available on Eyre's Peninsula for dairy produce, farmers would be well advised to give more attention to dairying as a sideline.

Coonalpyn Branch.

With the good attendance of 25 members and eight visitors at the November meeting it is evident that interest is being maintained in the Agricultural Bureau at Coonalpyn.

At this meeting Mr. F. Smedley chose as the subject of his paper, "Cows as a Sideline on the Farm." He expressed the opinion that dairying was one of the profitable sidelines for the wheatgrower. So far as their district was concerned, he believed that cows—and, as a natural consequence, pigs and poultry—would add very considerably to the revenue-earning power of the holding. The building up of the dairy herd would naturally depend on the finances of the farmer. Good cows were, of course, necessary, but the services of a bull with ancestors of proven productivity were essential. If top prices were to be realised for the products of the dairy, then strict attention to thorough cleanliness of all equipment was most important. Concluding, Mr. Smedley said that after 30 years' experience in the handling of dairy produce, he was convinced that the success of dairying depended absolutely on keeping a good class of cow, giving her every attention, and keeping everything connected with the industry clean. (Secretary, C. C. George.)

HORTICULTURAL OPERATIONS.

ESTABLISHING A VINEYARD.

At the January meeting of the Light's Pass Branch, which was attended by 14 members and visitors, Mr. P. Mader read a paper on the above subject. "Select and root your own cuttings, because if they are purchased from the nursery the varieties are often mixed. The cuttings should be about 16in. to 18in. long, and prepare the planting trench—which should be 2ft. wide and 2ft. deep—with a spade in preference to the plough. Fill in the trench with 1ft. of earth, then set the cuttings in position, leaving one bud above ground level, and press the soil with the foot very tightly around the cutting. Plant the cuttings in August in order that the land will be well soaked before the end of the winter rains. If the soil becomes dry, give an occasional good soaking with water. Prepare the site on which it is intended to make the vineyard some time ahead of planting so that weed growth will be reduced to a minimum. In marking out the block, a wire is preferred to string, because the former does not get blown about with the wind. Keep the top soil from the holes separate from the subsoil, so that when planting the cuttings the surface soil can be placed around the roots of the cuttings. The holes should be 1ft. square by 18in. deep. Prune the cuttings back to two buds, removing as well all the top roots, leave the others about 4in. long.

THE PLOUGH.

Mr. E. G. Lehrmann said ploughing was one of the most important operations in the cultivation of a vineyard or orchard. It is estimated that the cutting of a furrow with a sharp share requires about 60 per cent. of the total draught of a plough. If the draught of an ordinary double furrow plough is reckoned to be two tons. then cutting the furrows will account for about 25cwts. Experiments have shown that a blunt share may increase the latter by a further 40 per cent., which would mean a further increase of half a ton. The turning of the furrows with a short mouldboard in land of a sandy loam is estimated at 12 per cent. of the draught, but this may be increased by long mouldboards in sticky soil conditions. Knife coulters should always slant well forward, otherwise they catch the weeds and increase draught. Anything that can be done to shorten the distance between the horses' shoulders and the last mouldboard will very considerably lessen the draught. It is a mistake to work horses with chains that are too long, for this represents a great loss of power. Lightness of draught in a plough, however, is not the only point to be borne in mind. If the property consists of heavy soil, it may be necessary to give consideration to an implement that will go into hard ground. Keep all shares tight. Socket shares are much to be preferred to the plate type in stiff soils. Short mouldboards, whilst being light in draught, do not make a good job in heavy soil, because they leave the ground too hollow. Long or medium length mouldboards with deep set coulters should be used in sand; they leave ridged furrows which materially assist in checking drift." (Secretary, C. Verrall.)

MODERN METHODS IN THE DAIRY.

Mr. V. Gurr read the following paper at a meeting of the Tweedvale Branch held on 19th September, 1935. "In times of low butterfat prices the management of the herd calls for a good deal of attention if one is to receive the best results with as little expense as possible. The bull is half the herd, and no keen dairyman should be without a pure-bred bull. Bulls of any breed can be purchased under the Government subsidy scheme, providing they are from tested stock. A bull at all times should be treated with suspicion; he should be kept in a yard where he has plenty of exercise. He should also be well fed. The reason why a bull should be yarded is that the service to each cow can be regulated, which in a large herd with a young bull means a great deal to the life of that bull. A bull should not be allowed to serve each cow more than twice. I advocate a pure-bred bull of high producing stock of whatever breed a dairyman fancies, because such an animal costs no more to feed than a scrub bull, and he will also improve the butterfat standard of the herd. As regards the cows, herd testing and good feeding are the only sound and economic ways to carry on dairying successfully.

Feed in bails, because the feed can be rationed out economically according to the production of each cow. Dairymen cannot afford to feed a cow giving between 100lbs. and 200lbs. of fat a year with the same ration as a cow giving between 400lbs. and 500lbs. of fat. A cow should have six to eight weeks spell and always be fed during that time. It gives her a chance to feed the unborn calf and also to build up her system. Dispose of all culls or low producers. Do not sell them as soon as dry, but keep them for a little while if they are sound (if possible) until they put on a little more condition, and sell them with calf at foot. Avoid buying from the sale ring; there are some good clean cows sold that way, but there is always the chance of introducing disease into a herd. A calf should receive the colostrum (the first milk from its mother) for the first week. It should then be fed on whole milk—1gall. per day—for about a fortnight, and then gradually given skim milk. Do not over feed; it leads to scours. Because of the low price of butterfat, this method is preferable to the buying of other foods. Calves should be kept on milk until four months old. A little clover hay should be available for them to chew as soon as they will eat. Regularity should be practised in dairying, both in milking and feeding. (Secretary, B. Schapel.)

FODDER CONSERVATION.

Mr. A. C. McMillan read the following paper at a meeting of the Mount Gambier Branch held on 6th September:—Fodder conservation is a matter of greatest importance to future development, which will in the next half century increasingly veer towards the adoption of methods of feeding at present only to be seen on rare occasions, and to the provision and conservation of food as a regular and routine practice. The days of easy pastoral conditions have departed. Internal parasites have changed that, and it is now imperative that stock should be kept in health, in order to have the strength to resist the various troubles which have come in the train of settlement. There is no need to associate the term "fodder conservation" with the idea of drought. If that be so, the question of conservation of fodder will be set back a century. The psychological atmosphere in which this question has been wrapped up of late years has definitely retarded its progress. It has been known for many years that the value of food enables sheep to withstand internal parasites, and many associated deficiency diseases can be overcome by judicious management in feeding. Fodder conservation is of vital necessity for the well being of this district. In the early days when stock were running on virgin country they did well, but with the advance of closer settlement we find numerous ailments, due to the fact that we are getting away from Nature's balance. The question of expense need not deter anyone, because there are many methods advanced to-day whereby the only cost entailed is the getting and carting. The actual experience gained by those who have adopted fodder conservation shows that the bogey of expense very often scares the would-be conserver, whereas in actual practice it is nil. Another retarding influence has been the undue stressing of silage.

To many men the term "fodder conservation" means silage and nothing else. Valuable though silage is, it is far from being the only form in which food reserves can be built up. A great deal depends on the purpose for which the fodder is used. Fodder conservation bears much the same relation to livestock as a fire insurance policy on a homestead, with this added advantage that the fodder, if stored under certain conditions, has a sale value as well. One of the best methods of preventing periodic setbacks to stock is recognising the value of fodder conservation as a means of insuring better grown and more productive and healthy stock. It has always been a strong point with stud breeders that young growing animals must not suffer a setback. The owner insures this by having at hand a constant supply of feed in addition to grazing, and varying the amount used in accordance with the quality and amount of grazing. The ill effects of periodic setbacks, to which Australian livestock are subjected, is not sufficiently recognised, nor has the value of avoiding setbacks been properly understood in the production of beef and high quality fat lambs. It is quite impossible to ensure a continuity of nourishing food in this country without conserving fodder, or laying down improved pastures and manuring them heavily.

The latter process is really, in a way, a form of fodder conservation, but it is not universal in its possible application. How is it possible to expect dairy cows to yield highly and bear a vigorous calf regularly, in face of the semi-starvation to which so many of them are subjected almost every year, and that too often in the late winter and early spring just before coming into full milk? No poultry farmer would expect his fowls to go on laying or to fatten without food. The poultry farmer has probably, more than any other owner of stock, recognised the necessity of a constant supply of nutritious food in balanced form. Viewing the question from another aspect one sees that the resisting power of livestock as expressed in the capacity to thrive in face of infection, is to a large extent governed by food. Care must be taken, however, not to push this theory too far. Thus, there is no evidence that feed influences the susceptibility of cattle to contagious abortion, pleuro-pneumonia, or mastitis, but there is very definite evidence that feed influences the resistant power of sheep to the ordinary stomach and intestinal worms and their harmful effects. Further, the absence of certain required constituents from the food will quite certainly tend to bring about such abnormal conditions as sterility in one of its many forms, osteomalacia, rickets, grass tetany and milk fever. Moreover, it is clear that much of what is called preparturient apoplexy in sheep is due to food deficiency, and entero-toxaemia to an excess of food in certain directions, an excess which could be balanced by stored food of the right type. Much of the botulism which occurs could be prevented by the judicious use of stored fodder. These examples are probably sufficient to indicate the importance of a study of this subject. (Secretary, N. R. Aslin.)

ESTIMATING HAY YIELDS.

Paper read by Mr. C. J. Whillas at a meeting of Green Patch Branch held on 5th December:—When hay cutting most farmers wish to know the yield, and it is usual to estimate same from the weight of binder twine used. This is quite all right provided proper judgment is used, but it can be very misleading, for twine under some conditions will tie fully twice as much as under others. The factors that regulate the ratio of twine to hay weights are as follows:—

(*a*) Circumference of sheaf at the tie, *i.e.*, the size of the sheaf.
(*b*) The length of twine taken for knot and waste cut.
(*c*) The quality of the twine.
(*d*) The tightness of the tying, *i.e.*, the tension on the twine and the compression on the trip.
(*e*) The height of the crop.
(*f*) The density of the hay.

Of the above, the circumference of the sheaf is the main factor, for the reason that the contents and therefore the weight of a sheaf vary as the square of the circumference. For example, take a binder in a given crop; set it to throw out a 12in. circumference sheaf. The knot and waste cut will take up, say, 5in. twine. Then alter the machine to tie a 24in. circumference sheaf. The latter sheaf will weigh four times the former, using 29in of twine as against 17in. The variation in twine weight to hay weight ratio will therefore be 68 to 29, or in other words, the twine with the big sheaf will go more than twice as far as with the small. It is not suggested that a binder can be altered to the extent mentioned above, but years ago I tried out this matter on a new machine and was definitely able to prove that approximately a two to one difference could be made in twine used per ton of hay cut by altering the size of the sheaf. The twine used in the knot and the waste cut varies a little according to the make and the condition of the binder. It is obvious that the quality of the twine will make a difference in the twine-hay-weights ratio, because the dearer twine has greater length per pound. It is also obvious that a tight, compact sheaf will give a lower ratio of twine weight to hay weight than will a loose sheaf.

As to height of crop, one would not expect twine to go so far per ton of hay in a 2ft. high crop as in a 5ft. high crop; though the difference is not so great as one would expect, certainly not 5 to 2, for the reason that with the short crops the result is a very untidy sheaf with quite a proportion of the hay not caught within the band.

As regards hay density, there is considerable variation in the weights of hay per cubic yard from different crops, and this, of course, influences the ratio of twine weights to hay weights. It can be seen therefore that it is necessary to use a good deal of judgment in estimating hay weight from twine used. Speaking from 30 years' experience, during which I have always checked up my hay weights and twine used weight in every possible way, I have found, using medium quality twine, *i.e.*, 475ft. per pound twine, on average oaten hay crop and cutting a 7lb. to 8lb. sheaf results in approximately 60 tons of hay per cwt. of twine used. For the last few years crops have been heavier and results have been 70 tons and over per cwt. of medium quality twine used, the sheaves averaging a bit over 10lbs.

The following method I have used for years to arrive at the correct twine-hay weights ratio:—When cutting under average conditions for the season's cut, have someone count the number of sheaves turned out per ball. Do this for several balls, in order to obtain a correct average. Then when the sheaves are dried out weigh enough to give a good average of their weight. It is then an easy matter to calculate the total hay yield from the twine used. To arrive at the hay yield per acre when cutting, count the sheaves turned out from several one-chain lengths of travel with a 6ft. binder, thus getting the average weight of hay produced from 1 chain by 6ft. This, in pounds, is approximately cwts per acre hay yield. Also check up twine-hay weights ratio later when chaffing by weighing the chaff cut, carefully weighing ties taken out, and allowing a percentage for the waste cut of the twine.

After the hay is carted and stacked, if the tonnage of the stacks is calculated from the formula used by the insurance companies, a further check can be made on the total yield. The tonnage thus given works out fairly accurately with actual chaff cut for sale. (Secretary, C. J. Whillas.)

CROPS FOR EARLY FEED.

One of the young members of the Baroota Branch, Mr. C. R. Mudge, read the following paper at the November meeting which was attended by 15 members and visitors. Oats and Cape Barley, he said, were the best cereals to sow for early greenfeed in the Baroota district. Cape Barley should not be sown in paddocks which it was intended to put under wheat. The better plan was to drill it in small paddocks. For 10 years he had sown barley on the same paddock and the yields were just as good to-day as they were when the land was first sown to this cereal. The crop should be kept well eaten down; if allowed to grow too rank and then grazed off it did not make a good recovery. Oats sown on land that would be fallowed the next year was a good way of handling that cereal, especially on sandy land. By sowing oats on such land in early March or April, the growth of weeds was checked and the land need not be fallowed so early which, as a consequence, reduced the period over which there was a danger of drift. This season (1935) wheat sown on land on which oats had been grown the previous year and fallowed gave better returns than early fallow. Of the varieties of oats with which he had had experience, Early Burt had proved good for early feed, but the crop became thinner each time it was eaten back. Lachlan was a better stooling variety when fed down, but it was rather difficult to sow because of the awns. It did not yield so well as the former variety and was more inclined to shake. (Secretary, E. Hulster, Port Germein.)

HOMESTEAD MEETING.

The September meeting of the Jamestown Branch was held at the homestead of Mr. W. E. Symonds. Among the questions from the Question Box which were answered were the following:—*Question*—Does it pay to top-dress grassland, with wool at 1s. per pound? *Reply*—With super at its present price it is a payable proposition, but any increase in the price of super combined with dry years or with a fall in the price of wool would make it unprofitable. *Question*—When is the best time for mares to foal? *Reply*—Most suitable period in the Belalie district is from the middle of August to the middle of September, thus allowing for heavy work to be completed without depleting the team. The foal would have the benefit of spring weather and the mare more time to recover before spring cultivating. *Question*—Which is the best time and method of sowing lucerne seed? *Reply*—Early autumn or early spring is generally most suitable. For dry districts early September is recommended, because frosts do not then damage young plants and growth is assisted by spring weather. September sowings are also less liable to damage by lucerne flea. The soil should be well worked and freed from weeds and sowing done by drill or combine. *Question*—Which is the best type of dairy cow for the district, and why? *Reply*—The Milking Shorthorn was favoured because the milk was richer in butterfat; it was a robust type of cow, with a higher production for quantity of feed than other breeds. (Secretary, R. B. Phillips.)

SUGGESTED ALTERATIONS AND IMPROVEMENTS ON FARMING METHODS, TO MEET THE TIMES.

Paper read at a meeting of the Hartley Branch held on 11th September:—Owing to the fluctuation of the various markets for farm products, the "average" man on the land to-day must in many ways change his methods and the various activities on his holding if he is to keep "holding" on and make his occupation sustain him and his family in reasonably comfortable circumstances. The question is, of course, State-wide, but the following suggestions would apply particularly to this locality. (It is not suggested that the changes can be all made in one year.)

The day of wheat farming as a major source of income appears to be temporarily over, and the landholder must seek other avenues for his revenue, so that the producer must become proficient in mixed farming. This would not present a very difficult problem, owing to the fact that for a number of years he has been carrying on the so-called "sidelines" of the farm. These should form the nucleus of the modern farm. On the normal, or average holding it is surprising what can be accomplished in this direction. However, it cannot be done without a general reorganisation of present conditions and hours of labour. Assuming that the main source of revenue is from the wheat crop, areas used for the production of grain can be reduced to bare necessities. The introduction of pasture grasses, which are known to grow abundantly in the locality, must be fostered. The land will grow good fodder with proper care and cultivation.

LIVESTOCK.

Invest in a small flock of sheep; some type that will produce wool and mutton, and meet the demands of the local markets. If uncertain of the type of sheep to commence with, obtain the advice of a local pastoralist, who in most cases is willing to give advice. Almost to exhaustion the cow has been called upon to supply the ready cash to carry on, and on most farms cows are found in numbers that make one wonder how they find sufficient food to exist. In the suggested "reorganisation" the herd could be cut down to a few cows of some reliable and productive strain. Have them tested, and if one is not paying for its rations, replace it with one that will. Breeding for milk or cream production, or, in the instance where the run is sufficiently large, to pasture a few steers for baby beef and the raising of calves should form part of the "reorganisation" scheme.

Horses, which the man on the land can ill afford to do without, should be of a type suitable for the jobs on the farm. For reasons, often sentimental, many old horses, who have outlived their usefulness, are kept on the farm to die, eating grass that would keep a good cow or a sheep or two. These "old stagers," hard as it may seem, should be relieved by a kindly bullet rather than kept in the paddock until, as is often the case, one of the team breaks down, and it is then called upon to take up its place again in the traces and be given a task at which it has served its time, being utterly unfit for the sudden change. A good brood mare or two should be kept to produce the horse which will be needed to replace those at present in commission when they become too old.

No farm is complete without its quota of pigs of the type sought and required by present buyers. Again, I stress the necessity of starting with type pigs. Pigs that are bred on the lines required command higher prices in the markets. Portion of the land should be set aside for a suitable run and pens constructed that will be suitable for correct housing. A good pig deserves a good, clean house, and a good mother should hold pride of place in the pen. The selection of suitable males to produce the desired type should also be given earnest consideration.

Again, no farm is complete without its stock of poultry. Perhaps a few turkeys, geese, and ducks to meet own and local requirements could be kept. But with fowls, the barndoor fowl of the nondescript type should give place to a good laying strain; if eggs are required, those that are known to be producers of good-sized marketable eggs. Buy the originals from a breeder who is known by repute to have the stock that produces the maximum of eggs in the laying period. The vital point, once the flock is established, is to cull out the poor ones, and cull rigidly. Once a hen has served her term as an egg producing machine, she should be consigned to the pot or to the poultry market.

HOUSING AND FEEDING.

Housing is of utmost importance and should be carefully considered before commencing. Feeding on correct lines—as with all other animals—should be strictly adhered to to get the best returns from one's birds.

Close to any homestead and near the water supply one usually finds soil suitable for a small garden, and a little judicious selection of vegetables known to grow satisfactorily should be made, and will supply the needs for kitchen use. The surplus, if any, will be readily consumed by fowls or pigs.

OUTBUILDINGS.

The outbuildings on any farm should be of such type suitable for its specific purpose, and in all cases should be erected in a tidy, workmanlike manner, and in a position most suitable to the management of its particular occupants. Implement sheds, horse stable, cowsheds, fowlhouse, and pig pens should be kept as tidy and clean as is possible, and not allowed to become delapidated.

One point that must not be overlooked is the water supply to the various yards and pens. Water plays a vital part in the life of all creatures, and its easy access by stock will materially benefit the health of the animals.

THE WORKERS.

The farmer usually has some growing boys, and they should be encouraged (even if only of school-going age) to take an interest in the particular units of the farm; one could look to the sheep, one the poultry, the cattle, &c. Give them the choice of their charges; allow them to show in the local show if possible. Endeavour to get them to keep a record of each line. Books should be kept recording the details of each, in expenditure and income. Discuss problems with them when all are together. Give advice and take it. Do not expect the lads to do the correct thing always. Give them a chance to follow their own ideas and initiative. They may have some latent talent that will be of considerable value, and they may make mistakes that will eventually assist them in later life. If the returns of the farm are insufficient to pay wages, see that the lads get "some" pocketmoney by way of a bonus, or the sale of portion of the marketable products. It is an incentive to work and fosters the habit of thrift. Nothing breaks a lad's heart more than to think his neighbour or his pals are getting a few "bob" to spend while he is obliged to toil away without any remuneration whatever, and he soon begins to become dissatisfied with the life—hence the drift citywards, with its consequent result that the farmer is obliged to employ outside labour.

HOME LIFE.

Home life should be attractive. Wireless or music of some kind should be available, also a good stock of reading material for leisure time should be at hand. Books of reference, dealing with farming problems, economic questions, and general literature should form portion of the library. The subscription to some agricultural papers should receive consideration, while a daily or weekly newspaper is indispensable. (Secretary, W. J. Brook.)

FATTENING POULTRY FOR MARKET.

The October meeting of the Cherry Gardens Branch was held at the homestead of Mr. J. C. Blakely. Mr. I. L. Stone read the following paper:—In deciding upon the breed of bird one would naturally select a heavy breed—Rhode Island Red, Black

Orpington, Indian Game, Light Sussex, or Barnevelders—birds that will grow quickly, because success or failure depends on the length of time before the birds are ready for market. Any of the above-mentioned birds are good, but crossbreds grow more quickly and are stronger and more healthy. At the present time we are carrying out experiments in this direction. It is necessary to have a continuous supply of prime birds ready for killing. Thirty-six hours after the chicks are first hatched feed them in the ordinary way with a well-balanced ration. This season excellent results were obtained from the following mixture for the first five to six weeks:—10lbs. bran, 8lbs. pollard, 5lbs. meat meal, 2½lbs. buttermilk flake, 16lbs. maize meal, 7lbs. wheat meal, and ½lb. common salt. Thoroughly mix and feed dry, with plenty of good, clean water always available. Once the chicks have received a good start many of the troubles are over, because good healthy stock rarely take disease, while poor, under-nourished stock are a continual source of worry. Should the birds have done well at from four to five months of age they should be ready to be topped off. This is done by putting them in closely confined quarters with a wirenetting floor, so that the birds cannot scratch. The object has been to grow a large, healthy frame, and now it has to put on flesh. Feed the birds on pollard and water only, mixed to a thick soup. With no exercise it is surprising how readily the birds put on weight. Up to the time of putting the birds in the fattening pen they will have cost from 1s. 8d. to 1s. 9d. per head, and with pollard at 1s. per bushel three birds can be fattened for 4d. per week. Three to four weeks in the fattening pen should be sufficient to finish off the birds to dress about 4lbs. in weight, which is about the weight required by most purchasers. (Secretary, A. B. Stone.)

WOMEN'S BRANCHES.

DISPLAY OF HANDICRAFTS.

In common with quite a number of other Women's Branches, members of the Warcowie Branch this year staged their first exhibition of women's handicrafts. At their meeting held on 23rd November there was an attendance of 19, including visitors from Jamestown and Hawker. Mrs. E. L. Orchard, of the Belalie Branch, opened the exhibition and Mrs. Bailey acted as judge. Amongst the articles included in the exhibition were knitted garments, coat hangers, quilts, afternoon tea tray, d'oyleys, handbags, dolls, preserved fruits, floor mop and polish, hooked rugs, needlework, crocheting, and recovered chair seats. Members were sincerely congratulated on the successful show that had been staged and were urged by the visitors to make the exhibition an annual event on the Branch's programme. (Secretary, Miss A. G. Avery.)

KARTE.

November 11th.—Attendance: 26.

The November meeting was held at the residence of Mrs. D. Flavel. After inspecting the home and garden, Mrs. Flavel read a paper "Rug Making," and exhibited samples of her handicraft. Members of the Men's Branch also attended, and were shown the crops and farm by Mr. Flavel. It was decided to hold a Bureau Exhibition on April 15th. (Secretary, Mrs. F. Atze.)

SOAP MAKING.

The Myponga Branch is one of the most recently formed Women's Branches, and at their meeting held on 16th January Mrs. R. Magor, in giving the following recipe for soap making, said she had found that the soap which she made in her home was quite equal to the manufactured article. Any fat or suet that is rancid can be rendered down and saved for the purpose. *Recipe.*—1lb. each resin and caustic soda, 6½lbs. fat (which must be free from salt), 1 tablespoon turpentine, ¼lb. borax, 1 cup each kerosene and cloudy ammonia, and finally 2galls. of rain water added when the soap is nearly done. Put on all ingredients to boil, except ammonia and soda, which should be added last. Boil until the mixture is as thick as porridge, usually about 2 hours. Stir constantly, and if it shows signs of boiling over, add ½ a cup of cold water.

PRESERVING FRUIT.

Mrs. Magor also gave the following hints for preserving fruit. Cook the fruit carefully and strain the syrup through a muslin cloth to make it clear: a light syrup for pears and peaches and a heavier one for apricots and quinces. To make the light syrup use 1 cup of sugar to 3 cups of water, and for the heavier, 1 cup of sugar to 1½ cups of water. Temperatures and times of cooking: Apricots, 180 deg. for ½ hour; apples, 180 deg. for 2 hours; pears, 180 deg. for 2½ hours; peaches and plums, 160 deg. for 2½ hours. (Secretary, Mrs. M. Bounds.)

GEORGETOWN.

December 12th.

Twenty-four members attended the December meeting of the recently formed Women's Branch at Georgetown, when an excellent paper "The Management of the Kitchen" was contributed by Mrs. G. Smallacombe. With the consent of the writer this paper will be included on the Agenda of the Mid-North Conference which will be held at Beetaloo Valley on 12th March. (Secretary, Miss J. Crawford.)

CAKE DECORATING.

Cake decorating was the subject of a paper read by Mrs. W. McKendrick at the December meeting of the Clare Branch, which was attended by 33 members and 6 visitors. The paper read as follows:—Roll all icing sugar and sift. Before commencing to ice the cake take a piece of 3-ply wood, cover with a paper d'oyley or paper, cut the top of the cake level, and turn the cake upside down on to the board. Brush over the cake surface with a little white of egg, or flour may also be used for this purpose. Cover the cake with almond or mock almond icing. *Recipe.*—1 egg yolk well beaten and 1 tablespoon melted butter, 1 tablespoon lemon juice, ½lb icing sugar, ½ cup coconut. If too stiff, add a little more egg yolk. Never add water or milk. Knead as for pastry dough on a board sprinkled with castor sugar, and then roll out and place on cake. *Almond Paste.*—1lb. icing sugar, 3lbs. ground almonds, 2 egg yolks, ½ tspn. essence. Orange or lemon juice may be used in place of essence. Sift sugar, add almond meal, and mix to a stiff paste with the liquid ingredients. The paste must be suitable for rolling; if it is too soft add more sugar; if too stiff, add a little more egg yolk. Knead as for a pastry dough on a board sprinkled with castor sugar, then roll and place on cake. When the icing is almost dry, give 2 coats of royal icing. *Royal Icing.*—1lb. icing sugar, 2 egg whites, a few drops of essence, 1 tspn. glycerine, and a drop or two from a clean blue bag of blue. To mix the royal icing, sift the sugar into a roomy bowl; keeping a spoonful or two in case the icing is too moist when mixed. Add all other ingredients; the whites of eggs should be slightly broken, but not whipped to a stiff froth. At this stage the icing should be stiff and very difficult to stir. Do not add more egg white, but beat the mixture vigorously with a wooden spoon or spatula for at least 10 minutes until it gradually becomes whiter, softer, and easier to handle. When the correct stage has been reached the spoon will stand upright in the mixture. The royal icing must be put on evenly, and each coat allowed to dry. The smooth shining appearance is obtained by dipping the knife into a deep jug of boiling water, shake the knife free from moisture, and smooth it carefully over the icing. The knife must be fairly broad, thin, and pliable. Repeat this practice until the cook is satisfied with the result. To glaze: add enough egg white to the royal icing so that it will allow it to flow evenly over the knife. Do not smooth with the knife. When not in use cover the basin of icing with a cloth.

Mixtures.—Egg yolk makes yellow icing; blue bag, blue; cochineal, pink; blue and pink, mauve; blue and yellow, green; red and yellow, orange; cocoa or chocolate, brown; pink and a few drops of coffee essence, brick shade. *Decorations.*—The modern metal icing pump makes the work very simple, and with a little practice all manner of letterings and patterns can be worked on the cake. To trace a design on a cake, obtain a copy of the required illustration and draw or trace it on to ordinary white paper. Then lay the paper on the hardened surface of the iced cake, and with a needle prick the design on to the icing so that the line of dots can be followed with the thread from the icing pump. *Coconut Frosting.*—1½lbs. sugar, ½ pint milk, ½lb. coconut, and a piece of butter the size of a walnut. Boil sugar, milk, and butter for 7 minutes, place in a bowl, and stir until it cools. Add half of the coconut, and stir until it thickens. Spread on the cake, and sprinkle the top with the remainder of the coconut. (Secretary, Mrs. McKendrick.)

THE WOMEN'S BUREAU.

Reading a paper on "The Women's Bureau" at the January meeting of the Monarto South Branch, the Secretary, Mrs. F. Liebelt, said it was only of comparatively recent years that organisations solely for the benefit of rural women had been instituted in Australia. Women in the country were not expected to have any interests outside that of home life. Gradually, however, the country woman had extended her activities beyond that sphere, and at the present time there was possibly no other organisation that provided better scope for her desire to be of assistance to her fellow women than the Agricultural Bureau. Women's Branches of the Agricultural Bureau were non-political and non-sectarian; they provided the opportunity for members to meet each month and exchange opinions on every aspect of domestic economy, and in scattered districts where facilities for social intercourse were almost non-existent, the Branches were the means of bringing the women folk together and making a break in the monotony of their daily lives.

The speaker paid a very high tribute to the value of the Annual Congress, where delegates from Branches all over the State met in conference to talk over subjects of interest to all rural women. Any woman from the country who was in Adelaide during the holding of the Congress should not miss the opportunity of attending at least one of the sessions.

The reading of papers by individual members was one of the chief educational features of the Bureau, and if members took an active part in the discussion that followed, the value of the papers would be considerably increased.

The regular attendance of members at all meetings and the offering of suggestions to maintain interest in the Branch would encourage other members to take an active part in the affairs of the Branch.

In the last few years Women's Branches had devoted much of their energies to the organisation of competitive exhibitions of women's handicrafts. These fixtures were becoming increasingly popular, and were well worth a place on the programme of every Branch.

Still another good suggestion was for members when reading papers on suitable subjects to supplement their remarks with a practical demonstration. Where Branches were reasonably close together, inter-Branch visits could be arranged with advantage to all.

Minister of Agriculture.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, 1936.

South-East (Upper), at Bordertown, Wednesday, 1st April (Mr. L. H. Butler, Secretary).

South-East (Lower), at Kybybolite, Wednesday, 8th April (Mr. A. S. Shepherd, Kybybolite, Secretary).

Dairying, at Strathalbyn, Thursday, 21st May (Mr. Reg. Sissons, Strathalbyn, Secretary).

River Murray, at Block E, Thursday, 18th June (Mr. J. C. K. Brigham, Box 65, Renmark, Secretary).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Lucerne Rust.

Following the receipt of diseased specimens of lucerne plants, forwarded by a subscriber to the *Journal of Agriculture* at Wilmington, Mr. T. T. Colquhoun, M.Sc. (Assistant Plant Pathologist at the Waite Institute) diagnosed the trouble as lucerne rust, and says very little can be done by way of treatment of the crop. Spraying is not practicable, and may even be detrimental to the crop, whilst giving very little protection. In many instances, however, the rust is parasitized by another fungus, and spread of the disease is naturally limited.

If the infection is not too widespread, the cutting, careful removal, and burning of the affected tops may be possible, but results cannot be guaranteed by this treatment, since spores will probably be left on the crowns to re-infect new shoots.

Top watering (sprinkling of the plants) is liable to aggravate the trouble, the wet foliage being favourable for germination of the spores and infection of previously healthy plants.

In Victoria experiments have shown that lucerne grows better under flooding than sprinkling, the foliage apparently preferring a dry atmosphere.

If the rust is widespread, complete renewal of the stand may be advisable. If this action is taken the present crop should be cut, left to dry, and preferably burnt, although it may be used for hay. Following ploughing, it has been found advisable in practice to plant a crop of barley in the succeeding year without any nitrogenous fertiliser, renewing the lucerne in the next season. This is a cultural recommendation, but is also advisable from the point of view of the health of the lucerne. It will also be necessary to examine the headlands for volunteer lucerne plants with the object of eradicating any diseased individuals.

Fire Control Legislation.

Asking for a ruling as to the liability of district councils for actions of fire control officers appointed by them under the Bush Fires Act of 1933, the Clerk of the District Council of Kingscote was advised by the Minister of Agriculture that:—

1. It is obvious that if a fire control officer appointed by a council is not himself liable in damages for any action, then the council cannot be liable.

2. It is considered that, unless a fire control officer acts unreasonably or negligently, or in excess of his powers, no person could claim damages in the event of, say, a firebreak being burnt. This would be the position, even if, through a mistake in judgment, the firebreak proved unnecessary.

3. If, however, a fire control officer did become liable for his actions, it would depend on the fact of the particular case whether the council also was liable. Under section 11 (5) the council may give directions to the officer, and in such a case, if the damage arises as the result of the directions, then, subject to the considerations outlined in paragraph 2, the council would be liable for the damages. If directions are not given, or, if given, the course taken by the fire officer is contrary to the directions, it is possible that in most cases no liability would arise.

4. In most cases, therefore, the chances of a council being held liable in damages are remote, and there is no necessity for amendment of the law.

Irish Blight of the Potato.

Asking if any means of preventing losses to potato crops by the disease locally known as potato wilt, the Secretary of the Clarendon Branch of the Agricultural Bureau has been informed by Mr. A. G. Strickland, M.Agr. (Chief Horticultural Instructor) that "It is presumed that the term 'wilt', as used by the Bureau, refers to 'Irish Blight,' a disease which was more prevalent in potato crops last season than is usual."

The disease is caused by a fungus *Phytophthora infestans*, and its development is favoured by moderate temperatures and high humidity, *i.e.*, muggy and humid weather. In South Australia the normal spring weather is such that Irish Blight does not give much trouble, but in a spring such as was experienced in 1935 the disease naturally makes progress, and occasions damage to crops. Many other fungus diseases (such as black spot of apples) were similarly favoured in the spring of 1935.

Given normal weather conditions next spring, it is not anticipated that Irish Blight will be as troublesome as in 1935, but nevertheless certain precautions are advisable.

In the first place, use only clean seed. The disease may be carried over in seed potatoes, and on this account the use of seed potatoes harvested from plants affected with Irish Blight should be avoided, if possible. If such seed must be used, or if the source of the seed is not known, it is advisable to pickle the seed before planting, *i.e.*, immerse for 1½ hours in a solution of 1lb. formalin in 20galls. of water. Although this treatment cannot kill disease within the tubers, it will effectively deal with disease on the surface of the potatoes, and, moreover, will assist in controlling the disease "common scab."

Having planted seed, the position in regard to Irish Blight depends largely on the type of weather experienced in spring. Even after exercising all precautions as to seed, the disease may turn up if the weather is favourable.

If the spring commences humid, it is wise to apply a Bordeaux or Burgundy mixture spray to the potatoes *before* any signs of the disease are noted. This spray will coat the foliage and prevent infection. If the weather continues wet, additional sprays should be given to maintain a protective coating on the plants. In regard to spraying, it is important to realise that the spray should be applied before the disease appears, or, at any rate, at the very first sign of trouble.

In the event of the weather becoming warm and dry after application of a Bordeaux or Burgundy spray, it will be quite safe to omit spraying, unless further extended periods of damp weather are experienced."

Ban on Matches.

The Minister of Agriculture (Hon. A. P. Blesing, M.L.C.) has caused a proclamation to be issued banning the sale, offering for sale, distribution, and use during the period between 31st October in any year and the 1st day of the following May, of any matches other than those made to strike only on a preparation affixed to the box containing the matches, or to a box containing matches of the same description.

The proclamation was the result of advice received of the manufacture of a certain class of match which was stated to be waterproof and specially treated for striking freely on any rough surface under the worst weather conditions. These matches would strike practically on any surface, such as the sole of a boot or even on portion of a person's clothing. The object of making a ban on this class of match was to minimise the risk of bush fires during the summer months. It was considered that these matches would be dangerous in the hands of children or other irresponsible persons.

Sheep Dips.

Sheep Dips.—The recent conference of Yorke Peninsula branches held at Arthurton made a request that a list of sheep dips, complying with the provisions of the Stock Diseases Act, should be published for the information of members of branches. The Chief Inspector of Stock (Mr. C. A. Loxton) has supplied the following statement:—Any sheep dip which, when mixed according to the directions of the manufacturer, contains not less than one-tenth per cent. of Arsenic estimated as arsenious oxide will comply with the notice published under section 30 of the Stock and Poultry Diseases Act, 1934. The following dips comply with this notice:—Bickford's Sheep Dip Powder, Cooper's Powder Sheep Dip, Cresco Sheep Dip, Dytic Fluid Arsenical Sheep Dip, Edwards' Sheep Dipping Powder, Lan-o-leen Arsenical Sheep Dip, Little's Tripolvos Sheep Dip, Little's Patent Powder Dip, Little's Poisonous Liquid Sheep Dip, Immunol Sheep Dips—Fluid and Powder, Imperial Sheep Dip, Pestkill Sheep Dip, Quibell's Powder Sheep Dip, Royal Sheep Dip, Sickle Powder Sheep Dip, Tic-toc Sheep Dip, Udip, Vacdip, Vallo Sheep Dip, Young's Arsenical Sheep Dip Powder.

Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of the following publications:—

"International Review of Poultry Science," Volume 8, Nos. 1-2.

"Intense Systems of Apple Culture," Bulletin No. 49. Ministry of Agriculture, England. Price, 1s.

AGRICULTURAL INQUIRIES.

[Replies Supplied by W. J. Spafford, Deputy Director of Agriculture.]

Phalaris Tuberosa.

The Balhannah Agricultural Bureau asks:—"What time of the year should Phalaris tuberosa *seed be sown in the Balhannah district?"*

Reply—In the Balhannah district *Phalaris tuberosa* should be seeded in the autumn—in April, if land is in good germinating condition, but otherwise in May. It is very important that the land should be clean and free from weeds, so that it is advisable to fallow the land, even if for a short period only, before attempting to establish the crop. *Phalaris* seed should not be mixed with other seed in ordinary conditions, and if a mixed pasture is desired, the other plants can be introduced after the *Phalaris* is one or two years of age. If the germination test has shown the *Phalaris* seed to have high germinating power, from 2lbs. to 4lbs. of seed per acre are ample. The seed can be mixed with superphosphate, provided that it is sown not more than 4 hours after mixing. *Phalaris tuberosa* can be cut with a mower or scythe, and is really good green fodder. In strong-growing stands the growth becomes so dense that it is a fairly heavy job cutting it, but it can be done without much trouble in most cases. Provided the hay is not left out in the fields too long after it has been cured as hay, it makes a really good hay, and is quite suitable for feeding to cows after being chaffed. Most of the larger firms of seedsmen carry good *Phalaris tuberosa* seed.

Oats for 16-25in. Rainfall Districts.

The Blackheath Agricultural Bureau asks:—"Which is the best variety of oats to grow for grazing purposes in a district with a rainfall of 16 *to* 25 *inches?"*

Reply—''Mulga'' is a good oat to grow for grazing purposes in a district where the annual rainfall might reach 25in. If it be grown for grazing only, better results would be secured from a mixture of about 30lbs. rye and 40lbs. oats per acre, the rye producing winter feed in greater abundance than will any other cereal, and the oats continuing to grow well into the summer.

Eradicating Couch Grass.

A member of the Monarto South Branch of the Agricultural Bureau reports that small patches of couch grass are appearing on his farm.

Reply—To combat this weed it is suggested that if used persistently and each time as soon as green appears in the patches, a solution of sodium chlorate in water will eventually kill out the couch grass. The solution should be what is known as 10 per cent.; that is to say, 1lb. of sodium chlorate in 1gall. (10lbs.) of water, and should be applied to the grass from a watering can. Best results are obtained after rain, and if the soil is dry, it should be watered before applying the solution. Care should be exercised when using sodium chlorate, as some materials that become dry after having been soaked with the solution become highly inflammable. The material can be purchased from Hardie Trading Pty. Ltd., South Road, Mile End.

Grasses for Lower Yorke Peninsula.

The Secretary of the Weavers Branch of the Agricultural Bureau asks:—''What grasses can be recommended for this district?''

Reply—There is only one true grass that can be recommended for the Weavers district —Wimmera rye grass—but of other grazing fodders, lucerne and King Island Melilot can be grown, and the early subterranean clover is worth a trial. Lucerne should be sown on fallow at the rate of 6lbs. per acre with 2cwts. superphosphate if the stand is required for 5 or 6 years, but if only required for 2 or 3 years, seed at the rate of 4lbs. per acre could be drilled into a stubble with 1cwt. of superphosphate. Depending upon the time when the rain fell, seeding should be done in April or May. Wimmera rye grass can be sown with a cereal that is to be harvested for grain, using 2lbs. of seed per acre. King Island Melilot can be sown with a crop, or broadcasted after mixing with superphosphate, using about 3lbs. or 4lbs. of seed per acre.

[Replies given by Mr. W. J. SPAFFORD (Deputy Director of Agriculture) to questions submitted at the Conference of Yorke Peninsula Branches, at Arthurton, on 4th March.]

Wheat-Sick Land.

''What is the best treatment for land that is wheat-sick?''

Reply—''In climatic conditions such as exist in most of the wheatgrowing districts of South Australia land becomes wheat sick fairly quickly when cereals are the only crops grown, and when the fields are not rested from cropping for sufficiently long periods of time. This wheat-sickness is purely a matter of over-cropping with similar kinds of crops, such as wheat, barley and oats, and in most localities is easily corrected. Where the rainfall is sufficient to permit of the growth of field peas, this crop should be grown to tone up the soil, after which good wheat crops will again be grown. If the land is to be cropped frequently, about one crop in three should be a pea crop. Under existing market conditions, it is a more practical proposition in many of our wheat-growing districts, including most of Yorke Peninsula, to encourage the growth of Burr clover, and if this very useful pasture plant is allowed to make strong growth, about every third or fourth year, wheat-sickness will be unknown. Wherever a rotation of cropping of bare fallow-wheat-pasture (in which Burr clover is prominent) is practised the land has never shown signs of becoming wheat-sick, nor does the trouble occur in a rotation of bare fallow-wheat-barley or oats-pasture (Burr clover), provided the clover is encouraged with top-dressing. The use of plenty of superphosphate and the regular resting of the land from cropping will prevent the occurrence of wheat-sickness where Burr clover is plentiful, and where this clover is scanty King Island Melilot should be introduced for the same purpose.''

Eel Worms.

''What is the best treatment for land infested with eel worms?''

Reply—''Unfortunately, once land has become infested with eel-worm, crops are always liable to attack by this pest if, for any reason, anything happens to retard their early growth. Because of this, where eel-worm has appeared, it is essential to do everything possible to ensure that cereal crops start off strongly, if damage is to be prevented. This can be done best by very careful fallowing, making certain that weeds, and particularly grasses and cereals, be killed whilst still very small. At seeding, heavier dressings of superphosphate should be used than would be the case if eel-worm was not present. After a bad attack of eel-worm, it is wise to delay the seeding of the field as long as it is safe, and then use early varieties.

When a cereal crop is showing signs of attack by eel-worm it should be fed down very hard by sheep, doing the job quickly by crowding a lot of sheep on to the affected area. Better recovery by crops often follows doing the feeding-off when the land is wet after rain, the tramping of the soil appearing to retard the activities of the eel-worm.''

[Replies given by Mr. W. J. Spafford (Deputy Director of Agriculture) to questions submitted at the Conference of Lower North Branches of the Agricultural Bureau at Owen on 27th February.]

Californian v. Cape Barley.

''What is the difference in feeding value between Californian Cape and Prior barleys for feeding to Livestock?''

Reply—Analyses of samples of Californian Cape and Prior barleys grown in South Australia show that there is very little difference between the two as grains to feed to farm livestock.

Nutrients.	Prior Barley— Composition.	Digestible Nutrients.	Californian Cape Barley— Composition.	Digestible Nutrients.
Water	13.3	—	13.3	—
Ash	2.7	—	2.4	—
Protein	8.0	5.6	8.3	5.8
Fat	1.3	1.2	1.7	1.5
Carbohydrates	70.7	65.0	69.1	63.5
Fibre	4.0	1.3	5.2	1.7
Starch equivalent	—	73.4	—	72.4

The content of the various nutrients is almost identical for both barleys, the only noticeable differences being that the Californian Cape contains 1.2 per cent. more fibre and 1.6 per cent. less carbohydrates than Prior. These differences mean that after a slight allowance is made for a lower digestibility of the Californian Cape, the starch equivalent—which is the measure of the fattening power of a foodstuff—is 73.4 for Prior and 72.4 for Californian Cape. Stated in another way: 100lbs. of Prior barley are equal in fattening value to 73.4lbs. of starch, whereas 100lbs. of Californian Cape barley are equal in value to 72.4lbs. of starch.

Wimmera Rye Grass.

''Would Wimmera rye grass, in the course of time, be detrimental to wheat growing?''

Reply—There is always a possibility of crops of a similar kind, when grown on the same land, deleteriously affecting one another, and because wheat and Wimmera rye grass are both annual grasses, growing in much the same way and at the same time of the year, there is a chance that the rye grass might eventually prove injurious to wheat crops. I doubt that this will prove so, because rye grass is grown as a grazing crop, and whilst this method of handling the grass persists it does not appear likely that it will be harmful to wheat crops. Because of its similarity to wheat—if managed in a similar manner—if it was carted off the land it might lower the fertility of the soil to the extent of affecting wheat crops, but this has not proved to be so with oats and barley, at all events when grown in a reasonable rotation-of-cropping with wheat, and they are more closely allied to wheat than is Wimmera rye grass. Wimmera rye grass may eventually become a bad carrier of ''take-all,'' but the grass has not so far exhibited any signs of becoming bad in this regard, and even if it does, we will be no worse off than at present, because it is most unlikely that it can get worse than barley grass as a host for the dreaded ''take-all.''

To date, Wimmera rye grass has proved wholly good, and a most useful addition to wheat-growing farms, and if continued to be handled in a manner similar to what is now the common practice, it is more likely to do good by increasing the organic-matter content of the soil than to do harm in any way.

Californian v. English Barley.

''Does Californian Cape barley take more out of the ground than English malting barley?''

Reply—Crops of Californian Cape barley generally take more out of the soil than crops of English malting barley, because the yields secured will be higher, and so more grain will be carted off the land. All of the cereals, wheat, oats, barley, and rye collect from the soil almost exactly the same amounts of the various plant foods per ton of crop produced. Crops of wheat, oats, barley, and rye grown in the same season, and yielding 1 ton of hay per acre, will all have removed almost exactly similar amounts of all the mineral plant foods.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

''Brimpton Lake'' asks treatment for a mare which stamps and bites her hind foot.

Reply—This is probably due to the presence of a small parasite. Try the following treatment:—Apply with a body brush a little of the following mixture, rubbing it in thoroughly:—Lysol, 4 tablespoonsful; raw linseed oil, 1 pint; shake well before use. Apply two or three times at three-day intervals. Sump oil from a car may be used, but in hot weather may blister the skin.

Secretary Blackheath Agricultural Bureau reports pigs with a ravenous appetite for fowls' manure.

Reply—Fowl manure is rich in lime and phosphorous, and this may be the attraction such manure has for pigs. In addition, however, this craving may also be due to a deficiency of protein in their diet. To remedy the mineral deficiency the following lick should be supplied:—Sweet bonemeal, 10lbs.; powdered limestone, 10lbs.; common salt, 1lb.; mix thoroughly. Allow pigs free access to the mixture at all times.

Secretary Agricultural Bureau, Marama, asks:—(1) *Is Berg oil a good medicine for horses?* (2) *Is Stockholm tar a good thing for stock for sore throats, colds, &c.?* (3) *A drench for cow getting to wheat?*

Replies—(1) Bergol is a proprietary preparation, and is not listed in any of the pharmacopias; therefore its formula is not obtainable. It is a preparation used extensively among stockowners in this State for the treatment of colic. (2) Stockholm tar is obtained from pine trees from Stockholm by a distillation process of the refuse woods. Tar has many properties, being antiseptic, stimulant, expectorant, &c., and, taken internally, is useful in cases of colds and bronchitis when a discharge is present. There is nothing to prevent stockowners using Stockholm tar. (3) The following drench is a serviceable one:—Baking soda, ½lb.; Epsom salts, ¾lb.; treacle, 1lb.; water, 2 pints; to be given as one drench. Baking soda should be given for two or three days twice a day in 2oz. doses, dissolved in a pint of water.

Conference Yorke Peninsula Branches: ''What is the cause of lack of milk in breeding sows a few days after farrowing? What could be done to avoid it?''

Reply—Some of the causes of this condition are:—Mammitis (inflammation of the udder).—This is fairly common. The udders become hot, painful, and very tender to the touch, and the milk supply ceases, or is low. The sow resents the young pigs sucking. Treatment.—Give sow a dose of Epsom salts, and rub affected udders with the following mixture:—Olive oil, 4 parts; liquid extract of belladonna, 1 part; apply warm. Prevention.—(*a*) See that sow's bowels are kept regulated prior and subsequent to farrowing. (*b*) Put in clean, warm sty for farrowing, and before doing this wash udder with Condy's solution. Any sickness of a generalised nature, especially if accompanied by fever, *e.g.*, inflammation of the womb, pneumonia, &c. The pregnant sow should have plenty of exercise, and should not be too fat. A suitable ration should be fed, bearing in mind that the sow has to provide nourishment for her young, and for this purpose it should contain ample protein. Where grain is mainly fed and no milk is available it is necessary to give green lucerne, meat meal (boiled rabbits), &c. Further, where skim milk is not available and grain is the main feed, the following mineral mixture should be fed:—Agricultural lime, 1 part; dicalcic phosphate, 1 part; common salt, ½ part; of this mixture add 2½lbs. to every 100lbs. of grain. (NOTE.—It is important that the lime be thoroughly slaked.)

Conference Yorke Peninsula Branches: "What is the cause of weak stifle in young stock. Would it be hereditary?"

Reply—This condition is not uncommon in young horses and is really a dislocation or slipping out of position of the small bone in front of the stifle joint. In acute cases, the leg is held in a semi-flexed position with the toe only touching the ground. In chronic cases, the bone during progression slips in and out of position with a clicking movement. *It is often hereditary in the horse,* but may be due to an injury. In acute cases, the dislocation can be reduced by forcing the animal to make a sudden movement forward, by backing or by passing a sideline around the pastern of the affected foot and pulling the leg into position. A blister is then applied to the region of the pastern. In chronic cases treatment may not be satisfactory. In young colts it may disappear as the animal gets older. A blister could be tried.

HORTICULTURAL INQUIRIES.

[Replies given by Mr. A. G. STRICKLAND, M.Agr.Sc. (Chief Horticultural Instructor) to questions submitted at the Conference of Lower North Branches of the Agricultural Bureau held at Owen on 27th February.]

"Has anything further been done in the matter of the depth ploughing test for orchards and vineyards?"

At the Balhannah Conference in November, 1934, a resolution was passed requesting that experiments be conducted on early and late ploughing for fruit trees. At a later date, it was discovered that the resolution should have read "shallow and deep" ploughing.

After this clarification, the opinion was expressed that deep ploughing of vineyards would be advantageous in non-irrigated districts, but doubted the possibility of gaining definite experimental evidence on the point, owing to the interaction of other vineyard factors in any experiment laid down.

Best orchard and vineyard practice would involve the growing of greenstuff—either a sown green crop or miscellaneous herbage—weeds, &c., during winter, and incorporation of this green crop or "weed crop" with the soil before budburst in early spring. When such green crop is turned under, it should be ploughed in as deeply as possible.

The question as to whether deep ploughing or digging operations during the period that fruit trees are in full bloom is detrimental to cropping, was made the subject of an experiment on the Blackwood Experiment Orchard. (The preliminary results of this experiment are shown in the *Agricultural Journal*, January, 1935, page 784). No ill-effects on the trees concerned in the experiment were noted.

"Does the continued use of sulphate of ammonia in vineyard and orchard prove detrimental to vines and trees?"

The continued use of Sulphate of Ammonia need not necessarily prove detrimental to vines or fruit trees. On soils which have a poor supply of lime—and such soils are not common outside the high rainfall areas—excessive use of Sulphate of Ammonia may lead to some depletion of lime. For every 1lb. of Sulphate of Ammonia applied, 1lb. of lime is transformed into gypsum, and gradually washed away by downward leaching. This lime depletion induced by the application of Sulphate of Ammonia is only of importance in soils already low in lime, *i.e.*, acid soils, such as are rarely encountered in the drier inland regions.

The only other possible detrimental effect of applying Sulphate of Ammonia in excessive quantities on orchard or vineyard, would be in relation to plant growth. Within limits, growth and yield of fruit trees or vines are correlated; *i.e.*, without good annual growth, fruit production will be restricted. On the other hand, excessive growth is opposed to maximum fruiting, and if Sulphate of Ammonia were utilised to promote excessive growth, or growth at the wrong time of the year, fruiting could quite easily be adversely affected.

This condition, *i.e.*, restriction of fruit production on account of excessive vigour, is not, however, encountered as frequently as the reverse, *i.e.*, low yields on account of poor vegetative growth.

Sulphate of Ammonia is a quick-acting nitrogenous fertiliser which is perfectly safe on most soils if applied intelligently. Application should be made in early spring in the case of most fruit crops, and quantities used should be sufficient to induce that moderate vigour consistent with production of normal crops.

"What is a profitable dressing of Sulphate of Ammonia for citrus trees, and the best time and method to apply same?"

Experiments at the Berri Experiment Orchard, and, in fact, in almost every centre in the world where citrus is grown, have indicated the necessity of applying nitrogen to citrus trees. In fact, without adequate nitrogen, yields decline, and the trees become definitely unthrifty.

The amount of Sulphate of Ammonia necessary to maintain tree health and good cropping depends largely on the nature of the soil, and on the cultural practices employed. It is, of course, sound practice to grow winter green crops between rows of citrus, and plough these under in early spring. Where peas, beans, or other legumes are used for green cropping, nitrogen is added to the soil from the air, and if green cropping is regular, the demands for inorganic nitrogen as Sulphate of Ammonia) may not be so pronounced. Organic matter is of first importance, and by green cropping, or the use of farmyard manure, &c.. the soil humus content must be maintained.

Having applied as much organic matter as possible, the amounts of Sulphate of Ammonia to be applied annually may vary from ½lb. to 4lbs. per tree, according to age, for trees up to eight years old. On older trees as much as 8lbs. to 10lbs. of Sulphate of Ammonia per tree, and even higher quantities have been applied with advantage. Exact maximum profitable quantities cannot be quoted, as these will depend on such factors as district, the soil type, the size of tree, the amount of organic nitrogen used, etc..

The bulk of the annual dressing of Sulphate of Ammonia should be applied in early spring (say August). Often the whole annual amount may be applied at this time, but it is sometimes desirable to apply portion as an autumn dressing. As an autumn dressing 25 to 30 per cent. of the full annual dressing may be applied in early autumn or late summer; however, if a dressing applied at such time stimulates excessive autumn growth, the dressing should be reduced, or even omitted, and applied in spring. Generally speaking, the maximum demand for nitrogen occurs in early spring.

All fertilisers should be placed as deeply as possible in order that they may quickly reach the root zone. Very often Sulphate of Ammonia is applied in a ring round the tree spread, and ploughed or cultivated under. If the fertiliser can be placed at the bottom of a deep furrow, this is very desirable.

"Has the Blackwood Experimental Orchard had any success with new sprays for Codling Moth?"

The following spray materials have been used (some widely, some only on an experimental scale) as sprays to combat Codling Moth. All these materials were fully discussed by a meeting of the Interstate Codling Moth Committee held last year.

1. *Arsenate of Lead.*—Standard spray; objection is residue on fruit.

2. *Barium Fluosilicate* (or *Dutox*).—This material also leaves an objectionable residue. Furthermore, it has not given as good control as arsenate of lead.

3. *Calcium Arsenate.*—In tests conducted in Queensland, this material has been shown inferior to arsenate of lead.

4. *Manganar Magnesium Arsenate and Sodium Aluminium Fluoride.*—These two materials also leave objectionable residue, and so far have not proved any better than arsenate of lead in controlling Codling Moth.

5. *White Oils.*—White oils alone, and in various combinations with derris, nicotine sulphate and arsenate of lead, have been experimented with, and some of the combinations have shown promise. Oil and arsenate of lead cannot be freely recommended later in the season, owing to the fact that it may leave a residue almost impossible of removal by either wiping or washing. On certain varieties (such as Cleopatra), and in certain districts, white oil alone has given much trouble in the form of fruit spotting. Experiments are in progress at Blackwood on this and other matters; and at present the use of white oil on the Cleopatra variety cannot be freely recommended in all districts.

6. *Nicotine Sulphate and Bentonite Sulphur.*—Recent work in America has shown this spray to be very effective in controlling Codling Moth. Bentonite sulphur is a compound made by fusing colloidal sulphur and "Bentonite"—a colloidal clay which occurs naturally in parts of America. The resulting compound has highly colloidal properties, and when used with nicotine sulphate in spray mixtures, fixes the nicotine sulphate so that it remains effective as a stomach poison, and contact insecticide over a much longer period than when used in other combinations. This new spray, together with other standard schedules, is being tested by the Blackwood Orchard this season; although giving apparently fair control of Codling Moth, the bentonite sulphur-nicotine sulphate spray has imposed a heavy spray residue on fruit, and, on present indications, this residue is going to be exceedingly hard to remove.

Work on various sprays for Codling Moth by the Department of Agriculture has been extended in the past year, and during the next few years, particular attention will be paid to the most promising of the non-arsenical sprays—white oil alone, and combined with derris or nicotine sulphate, and mixtures of bentonite sulphur and nicotine sulphate.

Until further work has been carried out, we are not in a position to suggest alternatives to the widely used materials—arsenate of lead, and white oil.

The former material will give effective control if sprays are timed properly, but involves wiping or washing of fruit for removal of residue. White oil used alone, or with nicotine sulphate in the last three sprays, will overcome the residue problem, but may lead to spotting injury of some varieties, such as Cleopatra.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1934-35.

[By ALLAN R. CALLAGHAN, D.Phil., B.Sc., (Oxon); B.Sc.Agr. (Syd.) (Principal).]

(*Continued from page* 906.)

PART V.—LIVESTOCK.

Livestock activities play a very important part in the work of the College; in fact, the management of the property is to a large extent directed by livestock requirements. I have already stressed the need for the incorporation of livestock as an integral and very essential feature of a true and permanent agricultural system. With the advent of livestock comes greater diversification of farming combined with an actual necessity to farm, to a greater or lesser extent according to circumstances, for the animals which are being maintained. In a general way, therefore, the management of such a mixed farm is very largely controlled by the requirements of the animals being carried from time to time. In this section of the report I desire to deal specifically with items of interest concerning the progress made in certain aspects of animal husbandry at the College. In doing so I am fully aware of the incompleteness of the report, but I also feel that much of the information gathered from certain phases of the work for our own use and guidance should prove of definite value to many who are concerned with similar practical problems of animal husbandry.

The 1934 Drop of Foals, the first sired by "Cyrus," was a particularly even lot.

THE HORSES.

The year 1934-5 with the horses was one of great interest, and one which should stand as a definite year of progress, for during the year the first progeny of the Clydesdale stallion Cyrus (2455 N.Z.C.S.B.) was foaled. Thirteen foals were reared; they all expressed great character and similarity indicating a very pleasing prepotency of the sire. These foals were inspected by many interested parties. Visitors, without exception, were surprised with their general quality.

It is of especial interest to note that not since 1916 have so many foals been reared at the College in one season. The number showed a substantial increase over the immediately preceding years, in fact, the average number foaled from 1920 to 1932 was four; in 1933, seven were reared; thus in 1934 and coinciding with the advent of Cyrus, the thirteen foals reared offer a favourable comparison.

Of the 1934-5 foals, one only was eligible for the stud book; this was a colt from the only Stud Book mare the College possesses, Kowai Gyp. This colt was named Roseworthy Nomad (C.C.S.B. 2166) and was sold to a purchaser on the West Coast soon after weaning.

Of the others, one filly has been registered in Appendix A and two fillies are registered as progeny and are eligible for Appendix B.

FEEDING TESTS WITH MARES AND FOALS.

As paddock feed was very limited and stubble paddocks did not last long, a definite programme of feeding the mares-with-foals was undertaken, and in order to measure the results of the ration and maintain the interest of students, the rations were carefully worked out, and weights of foals and mares followed during the course of the feeding.

A Loose Stack of Silage, made from volunteer growth, consisting chiefly of Burr Medic (or Burr Clover) and Self-sown Cereal, built in 1933, opened out in perfect condition for feeding the following year.

The ration feed was dependent chiefly upon what was available on the farm; it was assessed in accordance with the Morrison or Modified Wolff-Lehmann feeding standards. The results from the feeding were very striking and demonstrate the value of the ration.

The daily feed was worked out for a mare and four months old foal weighing together approximately 2,100lbs. and consisted of:—

35lbs. Wheaten Chaff.

20lbs. Green Lucerne.

4lbs. Peas } Mixed and crushed.
2lbs. Wheat }
2lbs. Barley }

½lb. Linseed Meal.

According to standard analyses of the constituents, the ration conformed with recognised requirements for a mare suckling foal, with a nutritive ratio of approximately 1 : 7.5.

On this ration, twelve mares and twelve foals did remarkably well and for the period 4th February to 28th February both the mares and foals in every case showed quite significant increases in weight. The average increase per day per foal for this first three weeks was 3½lbs., while the mares showed an average increase of 4⅝lbs. per day. For the period 28th February to 18th March, when the weaning of foals began, the foals continued to increase in weight, while the tendency was for the mares to remain more steady, although one or two continued to increase considerably in weight In the latter cases the foals did not benefit to the same extent and did not show the same high increase as those on mares showing less tendency to fatten.

A Close-up View of a Fork full of Silage, taken from the loose silage stack shown in the previous illustration. The fodder was beautifully preserved; its olive green colour and fruity odour made it especially palatable to livestock. The next two illustrations show sheep and lambs being fed with this silage.

One mare foaled out of season and she and her foal were placed immediately on the same ration as the above. This mare's foal showed a daily increase from birth of 3¾lbs., whereas the gain per day of the other foals from birth and up to the time of feeding them a full ration was only 2⅜lbs. While this work is by no means conclusive, it indicates that balanced, and more carefully arranged feeding of mares and foals will give results.

On weaning at the age of 5½ to 6 months the foals averaged approximately 750lbs. weight and they were fed the following ration:—

12lbs. Wheaten Chaff.
10lbs. Green Lucerne.
1lb. Peas
½lb. Wheat } Mixed and crushed.
½lb. Barley
¼lb. Linseed Meal.

Seven foals were shut off from the mares on the 18th March and fed the above ration and for the period 18th March to the 8th April, 1935, they showed an average daily increase in weight of 3½lbs. per head.

This gain in weight over the weaning period indicates that the foals received no check and is good evidence in support of feeding a well balanced ration at this critical period. A definite check in growth accompanied by a general debility and proneness to worms—so often associated with weaning—may be avoided by proper feeding. In this test the foals showed a thrifty, sleek, well-conditioned appearance throughout, with no tendency to harshness of coat which accompanies loss of condition when weaning is carried out without proper attention to growth requirements.

The Dorset Horn-Merino Half-bred Test Flock, with Lambs by Southdown Rams at foot being Silage-fed on the 2nd March, 1935, on the occasion of a field day. Note the bareness of the stubble paddock in contrast with the splendid general condition of both ewes and lambs.

All the foregoing is merely test work and is hardly experimental for the simple reason that no control lots were fed; in this connection, advantages of feeding are well known and it would not be fair to neglect the feeding of half the year's foals to prove a point that is common knowledge. The results here summarised are given as a guide to some and a point of interest to others.

THE FEEDING OF LAMBING EWES ON SILAGE UNDER DROUGHT CONDITIONS.

Throughout the Lower and Middle North districts and the West Coast, fat lamb breeding has made very rapid strides and with a buoyant lamb market the development is sure to continue. Farmers who study the position carefully must realise that there are times during the season when the market is well supplied; they must also realise that there are periods when very few really choice sucker lambs are available.

In the past two seasons the College has endeavoured to meet the early market and to demonstrate to the farmer how such can be done without risk of failure. By using Dorset-Horn-Merino half bred ewes mated to Southdown rams, an early lambing was planned in 1934. On this occasion the lambs were dropped at the end of February and the beginning of March and the flock was fed silage in stubble paddocks. However, the season opened early and with the lambs only 3 weeks old, excellent green feed became available. The risk had been run because of good silage supplies on the farm and fortunately the opening rains were early. From this flock of 100 ewes, 110 lambs were marketed and the first consignment was sold at the local Abattoirs market on the 4th June, 1934, for the excellent return of 28s. 10d. per head. The lambs from the whole of this flock averaged £1 3s. 3d. per head.

This in itself indicates the value of meeting the market early; to do so year in and year out involves a certain amount of risk as the opening rains—although fairly reliable—may be unduly delayed.

It is the occasional season when the opening rains of late April or early May are poor or not supported by good following rains that makes most farmers avoid any risk, and they mate the ewes so that the earliest lambing is in June. This is what the majority do, and consequently the market becomes congested in August and September, whereas few high quality lambs are marketed before July.

In a normal year—opening during April or May—the April-May dropped lambs grow much more quickly because the weather is much milder than in June and July and there is less loss of new born lambs for the same reason. These lambs are marketed almost two months earlier than the June dropped, and consequently in normal seasons realise much higher prices.

The problem of the farmer is to provide some means of feeding as a safeguard against a late opening of the season, because once the risk is removed, considerably greater returns may be obtained by the earlier lambing. To demonstrate how best this might be done, a trial was arranged using silage as the base and some grain as a supplement. The main idea was to see what could be done with silage should an emergency arise, and to make certain that there would be no fresh green feed available, 40 Dorset Horn-Merino half-bred ewes were mated to lamb in January. During January, February, and March the flock was fed gradually increasing quantities of silage with a little grain (⅞th peas and ⅛th wheat) as a supplement. The average rate of feeding was 3¼lbs. of silage and ⅓lb. of grain per ewe per day in addition to ordinary cereal stubble grazing. The lambs were maintained in very satisfactory condition until the first week of April when following opening rains at the end of March greenfeed became available. At this stage feeding was discontinued. On the 24th April the first draft was sold at an average of 74lbs. live weight; these realised 21s. 10d. per head. On the 29th May a further draft realised 22s. 10d.

At the time approximate costs of the feed supplied were as follows:—

	s.	*d.*
292lbs of silage at 10s. 6d. per ton	1	4
34lbs. of peas at 3s. 6d. per bush.	2	0
5lbs. of wheat at 2s. 8d. per bush.	0	3
	3	7

At first glance it may appear that the cost of feeding was high, but returns showed a net return of 18s. 8d. on the first draft and 19s. 8d. on the second draft; this, it will be admitted, shows the proposition to be profitable. The important point, however, is that this flock was fed for three months because of the purposely arranged January lambing, whereas one or two months is likely to be the limit of feeding during an ordinary late season. In this way such supplementary feeding as would be necessary would be less prolonged and so cheaper. Again, when these drafts of sucker lambs were available there were no others on the market or any likelihood of any for another two months, so that butchers were loth to buy at a high price when continuity of supply was impossible. This statement is substantiated by the sale of a draft of lambs of the same breeding marketed on the 25th June when sucker lamb was becoming more prevalent which realised 24s. 7d.

A Close-up of the Dorset Horn-Merino Half-bred Ewes and Lambs during feeding, taken on the same occasion as the previous photograph. It will be seen that, in spite of the photographer, the lambs and ewes are eating the silage with relish from the feed trough. Their flourishing condition is evident.

The price less 1s. or 2s. for feeding is a very attractive one and almost worth the risk of a late season, but with ensilage stored on the farm the risk is definitely removed and any farmer in the agricultural regions can avail himself of the possibilities of earlier lambing, providing suitable and adequate reserves are held on the farm.

EXPERIMENTS WITH PIGS.

During the year a feeding trial with pigs was completed and a separate and detailed report on this work was submitted by the Dairy Superintendent, Mr. R. Baker, and has been published through the *Journal of Agriculture.* The idea behind the trial was to test the relative values of wheat and barley with and without supplementary foods, and to demonstrate how best either barley or wheat could be utilised for the production of pork or bacon. Pigs of different breedings were represented in the trial, namely pure Berkshires, and crossbreds from the following crossings, Large White x Berkshire, Large White x Middle Yorkshire, Tamworth x Berkshire and Large White x (Tamworth x Berkshire).

HERE ARE THE FACTS

about cord in tyres

The cord casing is the foundation of the tyre. and Dunlop builds on the principle that the casing should be able to outlast the longest wearing tread.

Dunlop has immense advantages in building a longer lasting casing. It operates its own Cotton Mills at Rochdale, England, which are devoted almost entirely to producing tyre cords. Dunlop Tyre cords are British-made from British-grown cotton.

Because of the "Disc Doubler," an exclusive Dunlop patent, Dunlop tyre cords have *a greater degree of twist* imparted to them than is possible by any other known process, and also a higher standard of uniformity.

Dunlop Weftless Cord casing construction, which is used exclusively by Dunlop interests in Australia, has been proved superior to wefted casing fabrics. It ensures that every cord is not only completely insulated, but permanently held in position by rubber. It offers you the maximum assurance of long life, safety, comfort and blow-out protection.

There were Six Pens of Six Pigs each in the Feeding Trial carried out to compare Barley and Wheat as basal foods for pigs. The Pigs shown above were on the wheat, skim milk, and lucerne ration. Pigs of the following breeding, from left to right, are shown in the photograph:—Large White x Tamworth x Berkshire; Large White x Berkshire; Large White x Middle Yorkshire; Large White x Berkshire; Berkshire, and Tamworth x Berkshire.

Some very interesting results were obtained and they demonstrated the great value of supplementary foods such as skim milk, lucerne, and meat meal for balancing basal rations of either wheat or barley. Under the conditions of the trial and assuming the value of pork at 5½d. per lb., wheat fed to pigs alone, with meat meal, and with skim milk and lucerne, would be worth respectively 3s. 10½d., 4s. 7d., and 5s. 5½d. per bush., and similarly barley fed alone, with meat meal, and with skim milk and lucerne, would be worth respectively 2s. 10½d., 2s. 7½d., and 3s. 9¼d. per bush.

The pigs in this trial were fed to bacon weight, slaughtered by the Export Department and sent overseas, from where comments were received on the different carcasses in the trial. The pure Berkshire pigs, irrespective of how fed, were regarded an unsuitable for export trade purposes, being too heavy in the shoulder, too short and thick in the body and far too wasteful when cut up. The pigs of crossbred breeding with Large White or Tamworth sires were favourably commented upon. It appears now that both local and overseas requirements are coming more and more into line, and light fore-ends, long bodies and well developed hams are the leading characteristics required of a good bacon pig. Pigs carrying excess fat—especially on the shoulders and along the back—are not wanted, for in satisfying the demand for leaner meat, such pigs prove very wasteful when cut into joints and pieces.

Knowing the general requirements of the trade leads one to ask how best the requirements may be met, especially from the viewpoint of breeding? With this in mind an investigation was begun to test the relative merits of different breeds and crossbreeds on a balanced grain ration of as constant a nature as possible. It is proposed to deal with as many different crossbred types as practicable and so far pigs of the following breeding have completed their test, Large White x Berkshire, Tamworth x Berkshire, Large White x (Tamworth x Berkshire), Canadian Berkshire x Old Type Berkshire, and Tamworth x Large Black. The carcasses of these pigs have been sent to England and criticisms on each will be duly received.

This experiment will take some time to complete, but it should eventually supply some very useful information with respect to the most suitable breeding to follow to meet the export trade.

ENTERO-TOXAEMIA IN SHEEP.

"Has anything further been done towards a remedy for entero-toxaemia in sheep, and has a vaccine used against this disease proved effective?"

A considerable amount of investigation work has been carried out in Western Australia by the Council for Scientific and Industrial Research on this disease.

There is little doubt that the Western Australian disease is identical with that disease of sheep in South Australia known as "Braxy-like" disease and "Stinkwort Poisoning," and also with the disease of lambs called "Pulpy Kidney." The cause of entero-toxaemia has been discovered, and it has been found that the disease is produced by the action of a powerful toxin (poison). This toxin is manufactured under certain conditions in the small gut of the sheep by a special bacillus.

A vaccine has been produced which, when inoculated into sheep, has given very good results in enabling them to resist entero-toxaemia. Its use is recommended in this State. Investigational work is still being done on the use of this vaccine.

It is suggested that pregnant ewes be vaccinated in the early stages of pregnancy.

THE DRAUGHT HORSE.

[By F. H. FRANCIS.]

[*At a recent meeting of the South Australian Branch of the Commonwealth Clydesdale Horse Society, Mr. Francis, by request of the Committee, gave an address (illustrated by lantern slides) on "The Draught Horse." Mr. Francis stated that he was more deeply interested in the Clydesdale breed, and, as the Clydesdale embodied all the characteristics of the true draught horse, he dealt at length with this breed. Brief references were made to other breeds.*]

The Clydesdale horse, as the name would imply, originated in Lanarkshire, Scotland, through which district the River Clyde flows. There is, however, no authenticated data concerning its origin previous to the year 1715, when John Paterson, of Lochlyoch, on the estate and in the parish of Carmichael, purchased in England a Flemish stallion. This horse possessed great quality of hoof and limb—a character which he passed to his offspring to a very marked degree, and so improved the breed in the Upper Ward to make them famous all over Scotland. The Lochlyoch mares were, generally, browns and blacks. They had grey hairs in their manes and in their tails, occasional grey hairs in their coats and, almost invariably, a white spot on their bellies. This latter marking was always regarded as a distinct indication of purity of blood.

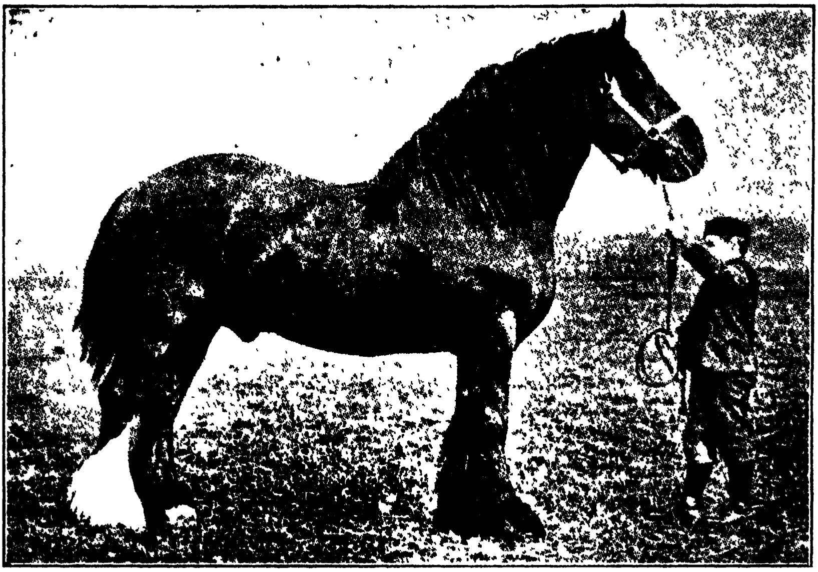
Another horse which greatly improved the breed was Blaze, purchased by a Mr. Scott, of Brownhill, Carstairs. Blaze was purchased as a two-year-old in Ayrshire about the year 1780. He imparted to his stock great style of action, very shapely bodies, and good wearing qualities of foot and limb.

More modern than the Lochlyoch or the Brownhill Clydesdales are those known as "The Lampit's Strain." At the dispersal sale of the stock of Thomas Clarkson, of Shott's Hill Mill, Parish of Carstairs, Lanarkshire, in the year 1808, Mr. Sommerville, of Lampit's Farm, purchased a two-year-old filly with which he founded his stud. This filly had several filly foals, all of which became famous brood mares, but it was as mother of Glancer that this Lampit's old mare, as she became known ultimately, was destined to become famous in the history of the Clydesdale breed. It is from Glancer that all the best and most noted Clydesdales are descended. Glancer is traceable through many generations back to the Lochlyoch mares and to the black horse of 1715.

In the year 1827, a new epoch in the history of Clydesdale breeding was inaugurated by the Highland Society holding its first open show for stallions and for mares. At this show, good prizes were offered for animals calculated to improve the type of horse for working heavy land along the valley of the Clyde. This gave Clydesdale horse breeding considerable impetus, and the breed became very popular, and its distribution very wide; so much so, that it became impossible to retain its progress in living memory. In the circumstances, some form of pedigree recording became imperative, with the result that the Clydesdale Horse Society of Great Britain and Ireland was founded. This took place in June, 1877, and the first or retrospective volume of the Stud Book was published in 1878. Since then, there has been an annual publication containing the pedigrees of, approximately, 60,000 mares and 25,000 stallions registered-numbered. Consequently, the pedigrees of Clydesdale horses are public property. The qualifications required for inclusion were three top crosses in the case of a stallion of Clydesdale breeding, and two top crosses for mares.

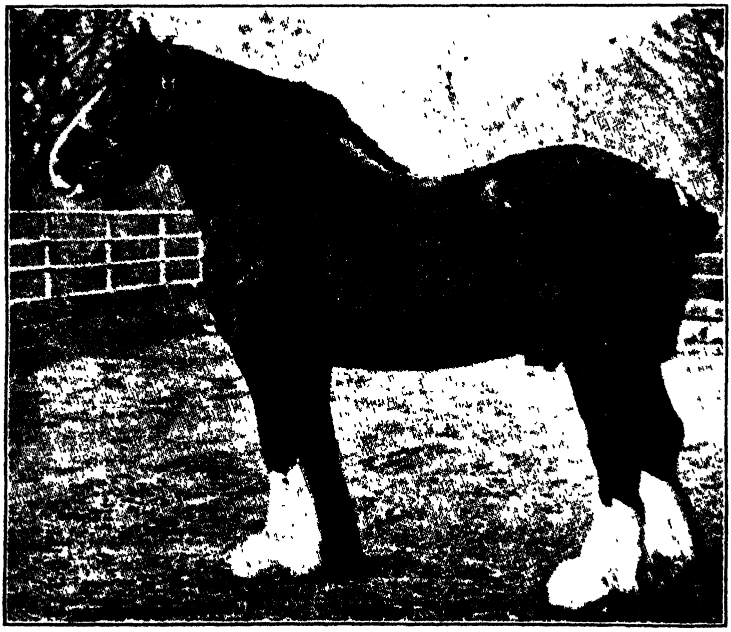
COMMENTS ON SOME NOTABLE HORSES.

Darnley was a very sound and good foundation sire, traceable to Glancer and to the Flemish horse of 1715. It is from Darnley that all the most fashionable lines of blood are descended. Comparing his lower limbs, more particularly the hind, with those of his third great-grandson, Baron's Pride, will give some idea of what can be accomplished by the application of science to breeding through selec-



DARNLEY, by Conqueror

time mating and correct breeding. Darnley was a leader in his day, winning many prizes at the Highland and Agricultural Society Show. He lived to the age of 14 years, and did the breed great service as will be noticed in the description of other horses mentioned later.

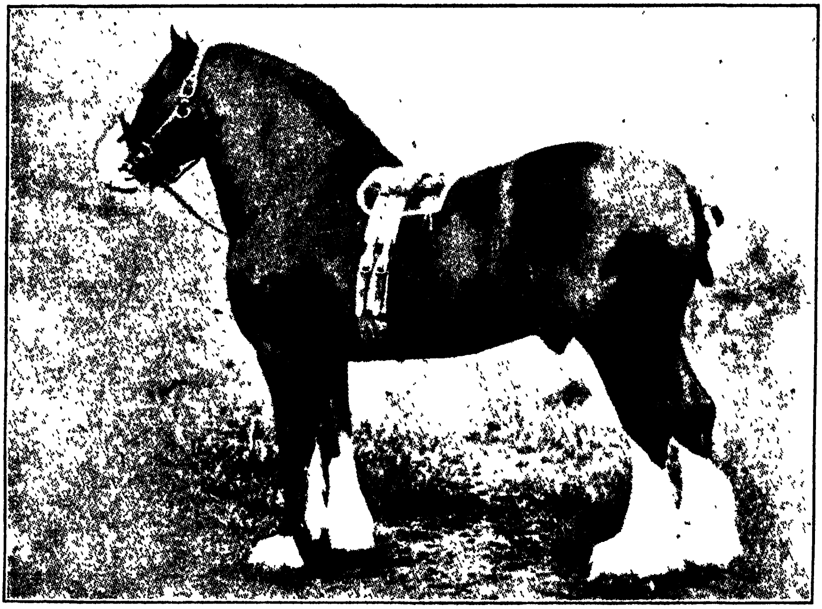


SIR EVERARD, by Top Gallant..

Top Gallant was Darnley's most famous son. An illustration of this horse which played an important part in improving the breed is not available. Top Gallant distinguished himself as a breeder in getting among others, that great horse Sir

Everard, which was an epoch-making sire. Here is the greatest line of blood known to the breed, showing a distinct change in the set of the limbs. Sir Everard was up to a big size, standing 17.1 hands at the shou'der, weighing 20¾cwts., and girthed 8ft. at six years of age.

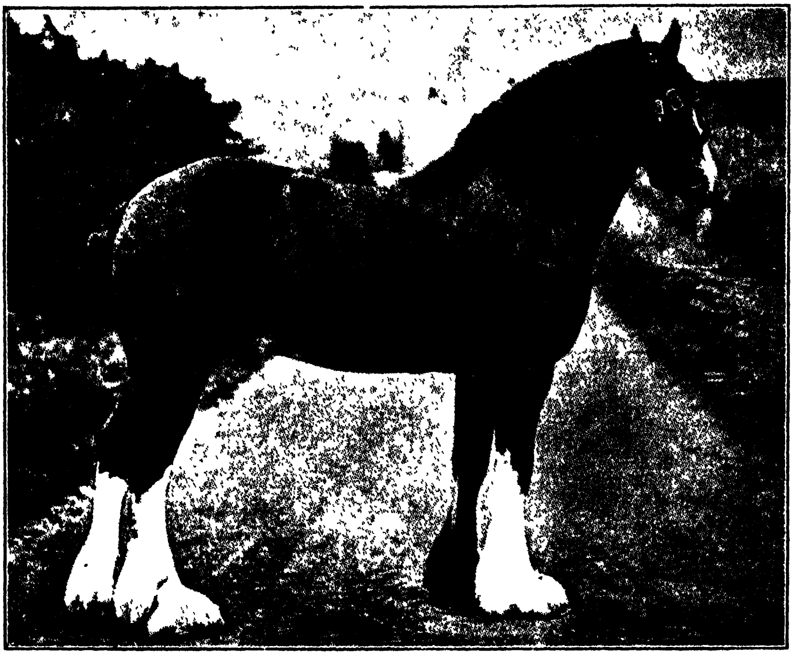
Sir Everard mated with the Springhill Darnley mare Forrest Queen, and produced the famous *Baron's Pride*. In this horse there was a great change in type and in character generally. The neck rose out of the shoulder tops; the fore legs were well in under the body and, above all, there was a distinct difference in the under pinning; the pasterns were much longer and set at a greater angle; the joints were more defined; the bones more flinty, with tendons well detached; the hock was higher up the leg and, in my opinion, this was the greatest step towards improvement in the evolution of the Clydesdale horse. This was a line-bred horse to Darnley, and was a great breeder both of stallions and mares. He passed his quality of foot and limb to his offspring, which was a very desirable character in those days. A great galaxy of champions were sired by Baron's Pride, and his influence is still very noticeable and his blood much sought after.



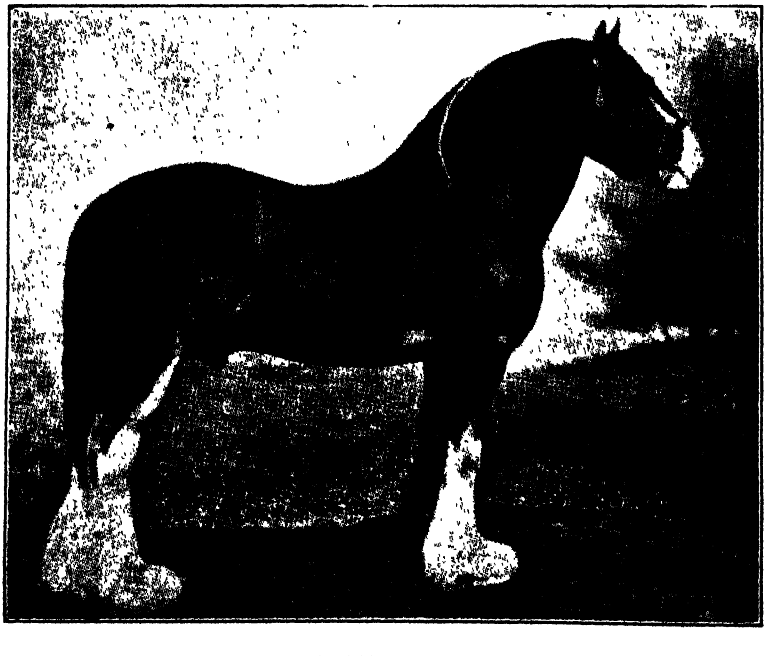
BARON'S PRIDE, by Sir Everard.

Baron's Pride united with the Knight Errant mare, Young Maybloom, and gave the world's record-priced horse, *Baron of Buchlyvie*, which was sold in the Ayr market for £9,500. He was a beautiful specimen and, like his sire, was well set up, with a perfect hind leg. Not only did he have a good hind limb, but, fortunately for the breed, this was a dominant character.

Before the Baron of Buchlyvie met his untimely end, by accident, he mated with the Auchenflower mare, Dunure Ideal, and gave the greatest draught stallion the world has known, *Dunure Footprint*. The accompanying illustration shows Dunure Footprint at 13 years of age, when he was at the height of his fame. Here we have two great blood lines springing from the one foundation, meeting in the culminating point of the production of the greatest family known to the breed. There were five full brothers and sisters, all of which won the Championship of the H. and A. Society in their turn. There was wonderful strength of character in Dunure Footprint's great masculine head; he had a grand full body; his legs were correctly put into him; his iron-grey colour shone like the sheen of silk; and he could move



BARON OF BUCHLYVIE by Baron's Pride

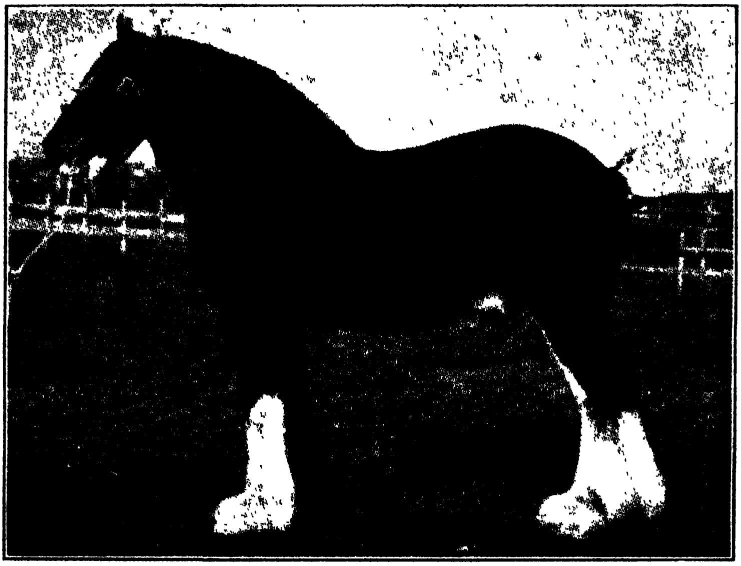


DUNURE FOOTPRINT, by Baron of Buchlyvie.

like an Iceland pony. Most of the show-winning horses in Scotland at the present time owe their merit to the influence of this great sire, and similar successes will follow in future generations of his line. Tracing his ascent to Darnley, he was by Baron of Buchlyvie, by Baron's Pride, by Sir Everard, by Top Gallant, by Darnley. He was line-bred, and it was through Auchenflower, the sire of Dunure Ideal—the dam of Footprint—that MacGregor came into the picture for Auchenflower was by Montrave Mac, by Macgregor, by Darnley. But there were other infusions of Darnley blood in the veins of Dunure Footprint. The sire of the dam of Baron's Pride, Springhill Darnley, was by Darnley, and again, Knight Errant the sire of the dam of Baron of Buchlyvie, was by Top Gallant. There was, therefore, a predominance of Darnley blood in this line-bred sire which was of such a wonderful breeding and showyard success.

Auchenflower was a great type of cart horse, and a very influential sire. Among the most famous of his daughters were Dunure Ideal, Wells Mescal, and Monk Gladys.

Rosencraig was one of Dunure Footprint's very best sons, and was exported to New Zealand by Mr. David Adams. Rosencraig has given great service to the breed in New Zealand, and there are some very fine stock by this horse in that country.

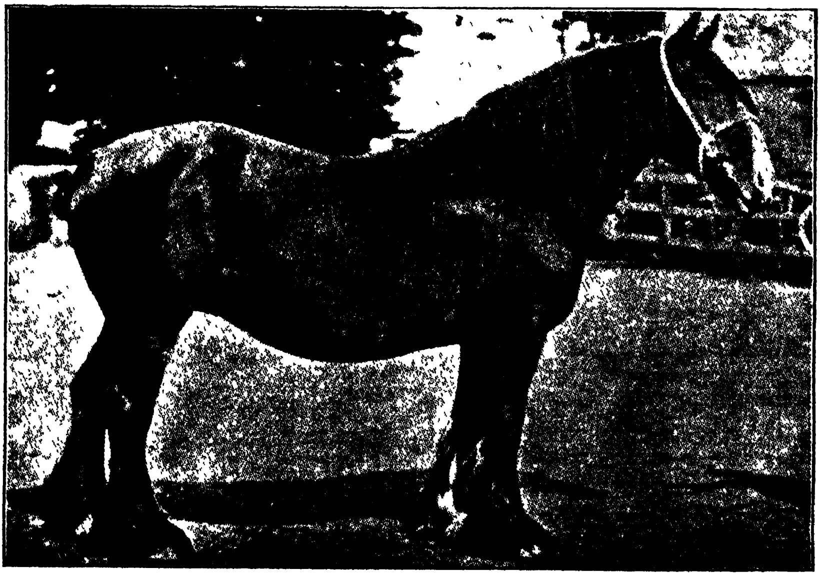


BENEFACTOR, by Fyvie Sensation

Hiawatha, by Prince Robert, winner of the Cawdor Cup on four successive occasions, was a great stud success, siring many good mares. The Cawdor Cup, the blue ribbon championship of the Clydesdale world, must now be won four times by the one exhibitor with different animals each year before it becomes his property.

Flashdale (imp.), by Dunure Footprint, from Harviestoun Amy, by Baron's Pride, was a line-bred horse, a Cawdor Cup champion, and a great stud success. Here again Montrave Mac figures in the pedigree, as the maternal grand-dam, Maud of Highborgue, was by Montrave Mac. Flashdale was a very true Clydesdale horse, and his value (through his daughters) is now dawning upon the breeders of Clydesdales in Australia.

Benefactor is a horse with a history. He was bred by Mr. Wm. Mecklem. His sire was Fivie Sensation, his dam Maud of Begg by Dunure Footprint. He was purchased as a foal from the breeder by Mr. Wm. Montgomery, in whose hands he had a very successful show career, and was never beaten in his class. When the colt was four years old, Mr. Montgomery decided to relinquish Clydesdale breeding, and called a sale in the Lanark Mart, when Benefactor realised £4,400. He had then made a name as a breeder, as his first crop of foals had caused a sensation in the show ring. The new owners were Templeton Bros., of "Sandyknowe," Kelso, and from the day that the Templetons acquired him "Sandyknowe" never looked back. In the month of March following his purchase by Templetons he won the Cawdor Cup. The next year he climbed into third place in the sires' breeding list—a proud position for a horse which had only immature animals to represent him. The following year he displaced the great Dunure Footprint from his position as head of the sires' breeding list, a distinction which the latter had held for 13 years. But it was in 1930, at the stallion show in Glasgow, that Benefactor put the cope-stone on his achievements by winning first in the class for veteran stallions, then the Lumsden trophy and, finally, winning the Meiklem Gold Cup for the supreme championship. This was a great performance for a horse eight years of age, and on which heavy demands had been made during the previous three years. Benefactor had thus gained every trophy open to a Clydesdale stallion. Though he died at the age of 10 years, he has left to date seven Cawdor Cup and many other great winners. There is no doubt that Benefactor will be regarded as one of the greatest horses of the breed. He has many beautiful sons and daughters, several of which are to be found in Australia, and they are a hard line to beat.



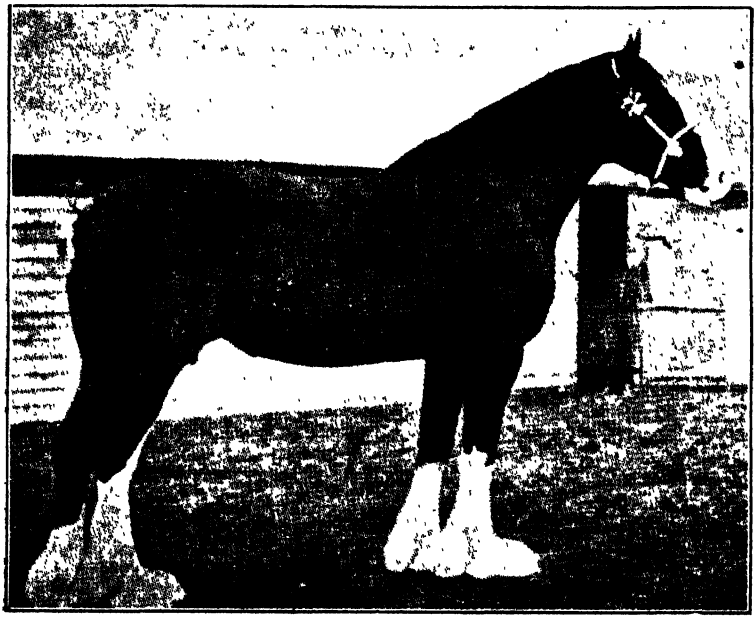
MOSS ROSE (when 13 years old), by Prince Charlie

Craigie Beau Ideal won the Cawdor Cup as a yearling, and since then has won every trophy open to a Clydesdale stallion. He is a very prolific breeder, and has now displaced the defunct Benefactor from the head of the sires' breeding list. His sire is Craigie McQuaid, his dam by Dunure Footprint.

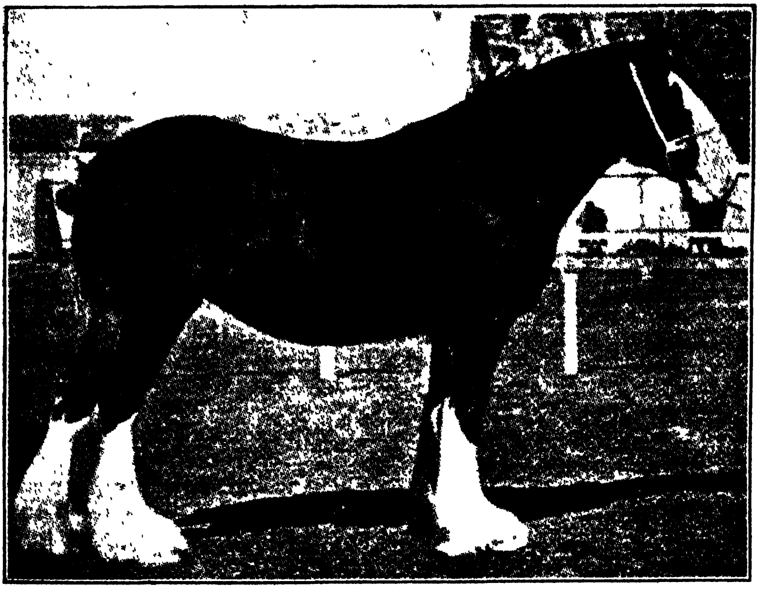
Beneficial, by Benefactor, won the Cawdor Cup as a yearling, and probably is the best young Clydesdale stallion at the present time.

FAMOUS MARES.

Moss Rose, was in equal regard, as a mare, with Darnley as a stallion. She was a very sound, good foundation mare with depth and substance, and a cup winner.



FARLETON LADY ALICE, by Dunure Footprint.



CHERRY BLOSSOM, by Dunure Footprint.

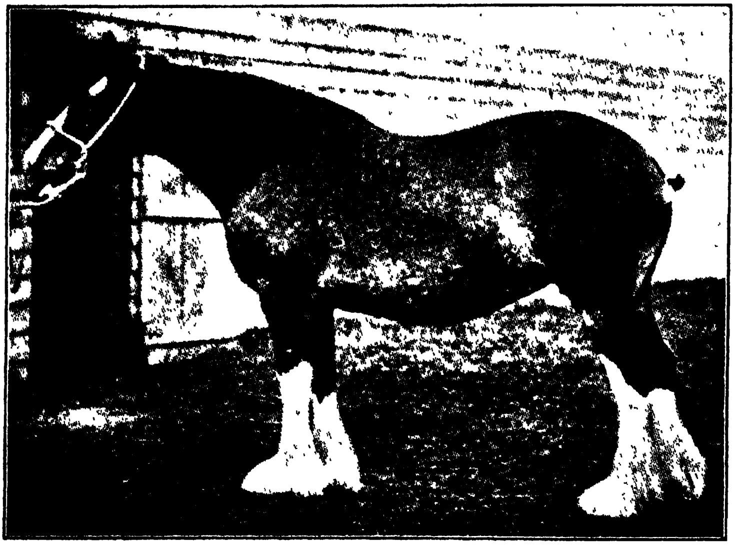
Farleton Lady Alice was one of the first daughters of Dunure Footprint, and was among the best of a great line got by that famous sire. She was the winner of the Cup on two occasions, as well as the Champion of the Royal Agricultural Society of England. She was well cut out at the ground, with beautiful class of bones.

Harviestoun Baroness, a daughter of Baron's Pride, was a Cawdor Cup winner.

Chester Princess, another daughter of Baron's Pride, was also a Cawdor Cup winner and, mated with Royal Favourite, produced the Cawdor Cup Champions, Scotland Yet and Harviestoun Phyllis.

Cherry Blossom was another of Footprint's daughters. She was described by the late Archibald McNeilage, at the time when her daughter, Mary Rose, was exported to Australia, as the best mare that ever led her class through Scottish show yards.

Dunure Ideal, by Auchenflower, was the dam of the greatest family of draught horses in the world. Very early in life she was destined to become famous in connection with the history of the Clydesdale breed. At 2 years and 9 months of age she won the brood mare class at the H. & A.S., and foaled Dunure Footprint the same night. She had four other sons and daughters that survived her, all of which won the H. & A.S. championship in their turn. Dunure Footprint and Dunure Chosen won the Cawdor Cup. Others of the family were Dunure Black Silk, Dunure Key Note, and Dunure Index. This is the type of mare to look for—full of breed character, great depth of rib, sharp hard bones, nice leashy feather and legs well placed into her great body. Dunure Ideal's fault was in her hind leg, which was a little too straight, and the hock was somewhat low down the leg. In this connection there is an object lesson showing what corrective mating will do. Baron of Buchlyvie was the sire with which this mare was mated. He had a perfect hind leg and, as he was dominant in this character, he overcame the only fault in Dunure Ideal. The result was that, as she was a mare of great breed character, she passed on all her good qualities to her offspring. This was what made her such a grand stud success.



DUNURE IDEAL, by Auchenflower.

Ambercrombie Emma is by Dunure Footprint, and is the dam of Craigie Ella, the Cawdor Cup champion by Craigie Litigant. She is now in Andrew Grant's stud in New Zealand.

Rosalind is full sister to Rosencraig, and is by Dunure Footprint. Rosalind was exported to Canada, and one of her daughters, Rosabell, bred in America, was brought back to Scotland and mated with Benefactor; produced Mr. W. G. Wilkinson's famous Faraway.

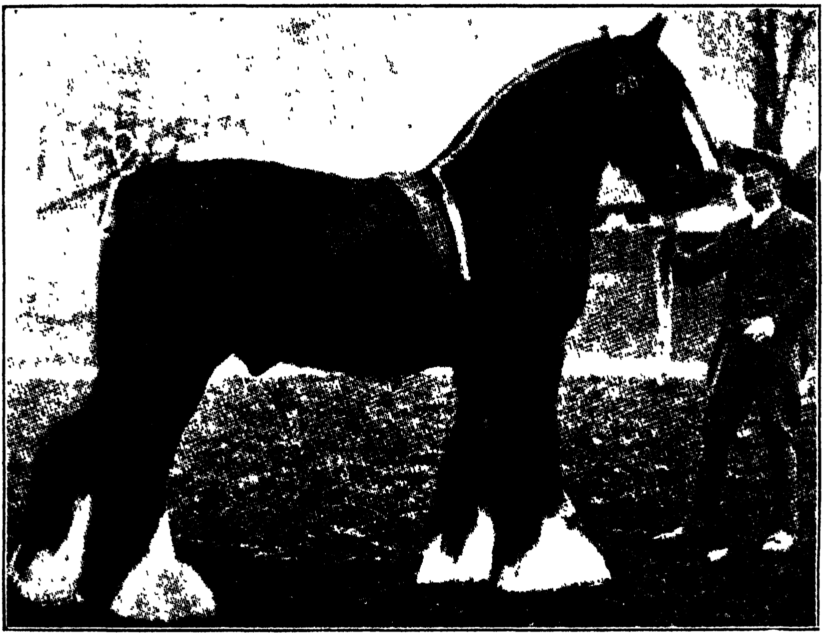
There are many very famous mares got by Dunure Footprint, including *Orange Blossom*, of which all Australian Clydesdale breeders are justly proud.

Onoway is the unbeaten daughter of Benefactor, and is breeding consistently.

Lane Lucky Girl, another of Benefactor's daughters, was a Cawdor Cup mare.

Powerful Link is another of the good class of mares, and is the property of Mr. David Adams.

There were many personalities who contributed to the success of the Clydesdale breed, and those of outstanding merit were the late W. Montgomery, of Nether Hall and Banks; the late John Finaly, of Springhill; the late Mr. Purdie Sommerville, of Sandilands; the late William Elliot, of Lanark Mart; and the late Archibald McNeilage who, for over 50 years, was Secretary of the Clydesdale Herd Society of Great Britain and Ireland.



SEEDSMAN, Shire Stallion.

SHIRES.

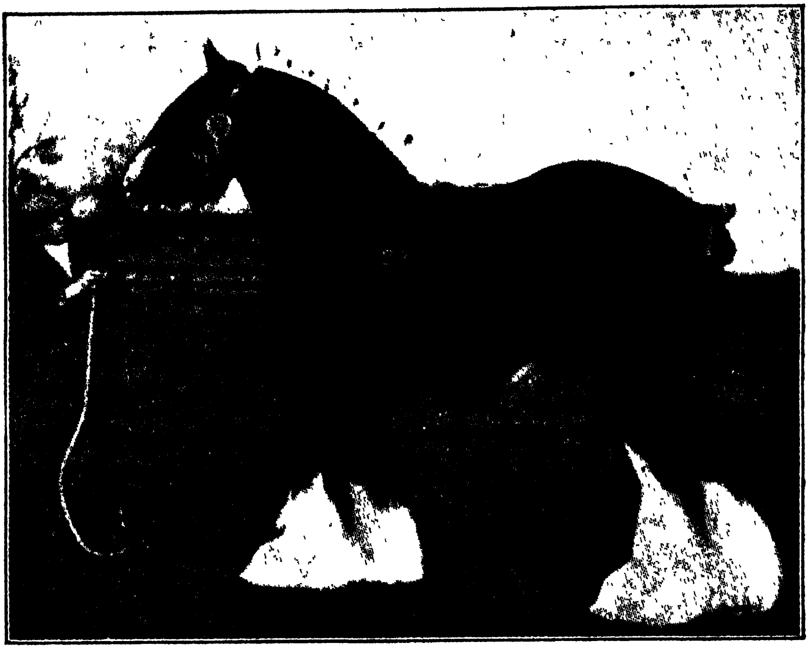
The Shire breed was largely developed and improved in the lowlands of east and central England, particularly in the district between the Humber and the Cain rivers, and extending to the Severn. The breed has been much improved by the introduction of heavy horses from Flanders, Holland, and Germany. Robert Bakewell improved the Shire Horse. The Shire Horse Society was founded in 1878, and a stud book established.

FAMOUS SHIRE HORSES.

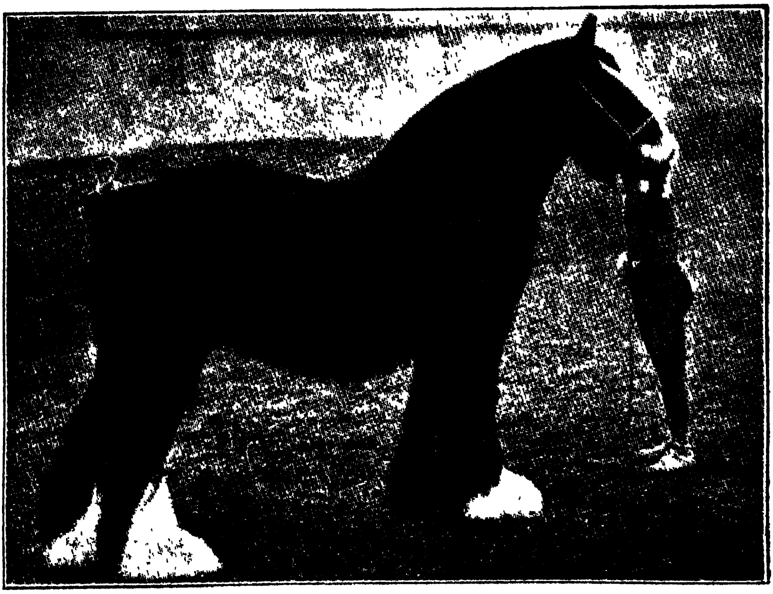
Seedsman was a winner of many prizes a few years ago. He does not, however, conform to the Clydesdale type.

Bower Winalot is quite a different specimen, and conforms more to the Clydesdale type. He was winner of the male championship at the London Shire Horse Show for the past four years.

Wick Lady Clansman is a specimen of the old type of Shire mare that was winning a few years ago.

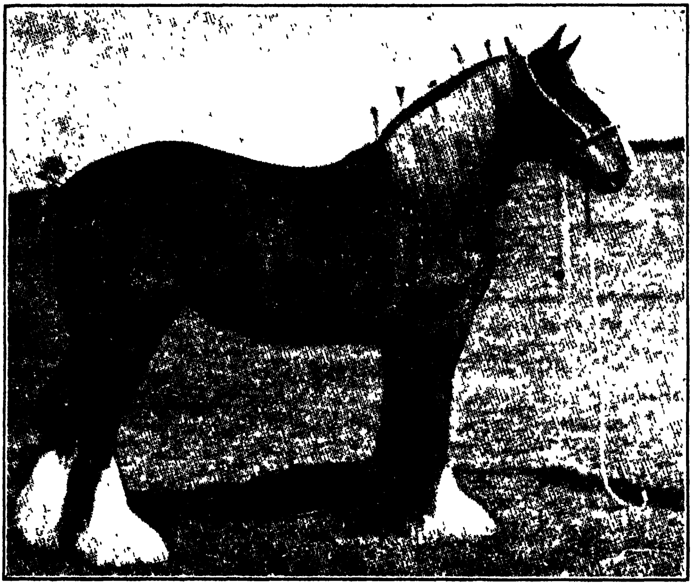


BOWER WINALOT, Shire Stallion.



WICK LADY CLANSMAN, Shire Mare.

Lymm Lady Grey won the female championship at the R.A.S.E. last year, and demonstrates the change that has taken place. She is nearer in type to the heavy Clydesdale than any Shire mare that has won the highest showyard honours. This change, brought about by judges favouring this type, is the greatest compliment ever paid to the Clydesdale breed. The most important factor which brought about this change was the judging of the Shire gelding section at the Highland Show by the late John Wilson a few years ago. A higher tribute was never paid to a Clydesdale judge.



LYMM LADY GREY, Shire Mare.

THE PERCHERON DRAUGHT HORSE.

Carburrutta is one of the famous Percherons, being successful alike at the stud and in the showyard.

Sheiden Archille is a good hardy type where the work required is hard and slow under wet conditions.

The Percheron would be a good horse where speed is not an important factor.

THE BELGIAN DRAUGHT HORSE.

The Belgian Draught Horse is a breed with an enviable record, for it is almost entirely the product of its own environment. All other breeders of draught horses added substance to their stock by the importation of ponderous sires from Flanders, the home of the Belgian horse. The people of Belgium are passionately fond of horse breeding. Their habits and the climate and soil of the country provide ideal conditions for the purpose. Since 1850, the Government has greatly assisted its people in the horse-breeding industry. The Government grant to assist horse breeding amounts to about £18,000 annually. This is given in special prizes at shows, and in bounties for approved stallions. Restrictions are placed on animals leaving the country. Bounties for the maintenance of mares are also given. The draught-horse shows of Belgium are notable events, because of the great amount of prizemoney paid. The annual show held at Brussels is by far the largest of its kind in Europe, the entries often running to 1,000. The Government of that country is to be congratulated on the fine assistance which it renders to this great national industry.

The Belgian horse is a very deep, thick animal, and capable of doing a power of show work. He is not just what the Clydesdale breeder likes at the ground, but these horses are much admired for their substance. However, the horse of any pure breed is not to be despised so long as he is up to the standard of his breed. The real menace of the industry in this country is the nondescript two-year-old, and breeders should therefore use approved, tried sires.

POINTS OF THE DRAUGHT HORSE.

A horse like Benefactor embodies all of the most essential characteristics of the modern draught horse.

When assessing the merits of the draught horse we first look to his feet, which should be deep and wide open at the heels, big at the crown, thick in the walls, with the pasterns cushioned into them at an angle of about 45 degrees. The pastern bones should be of good length so as to absorb concussion. The cannon bones should be hard in texture, sharp and broad. The tendons should be well defined, the reason being that the tendons never permanently lengthen with work, but they will permanently shorten unless they are well thrown back from the bones to give the bones the advantage over the tendon, keeping them at their natural length. This is important as while tendons have but little strength under compression, they are extremely strong under tensile strain. On the other hand, bones are very strong under compression, but are comparatively weak under tensile strain. It then becomes highly important that they be placed in the correct location.

The shoulder should be closely topped, deep and oblique, with the fore legs well back from the shoulder point and, viewed from the front, should be placed well in under the body. Here we apply mechanics, for, after all, it is a matter of angles and levers. It will, therefore, be seen that such conformation enables the animal to control properly the lower limb by lifting it up and thrusting it forward. The neck should rise out of the shoulder tops, and not out of the end of the body like that of a bobbie lizard. The head should be placed on the neck at the correct angle like that of Benefactor.

Breed character beggars description. Nevertheless, it is recognised by the born stock breeder when it is present in an animal. Without breed character the horse will be a stud failure.

The *hind leg* is the most important part of a horse's anatomy. The foot is not quite so large as the forefoot; it is somewhat deeper. The ankle is a little more inclined, and the toes slightly turned out. The shank is broader than the cannon, but of the same texture, and in the good wearing quality horse resembles in shape the blade of a hollow-ground razor. The hair flowing from the legs must be fine, free from curl, and hang from the back of the legs, both fore and hind. The hock joint should be broad, deep, and clean cut, the nape of the hock should point inward and upward, and should be close together both standing and moving. The hock joint should be placed high up the leg. This conformation not only increases the stride, but strengthens the leg, as it shortens the gaskin. This is most important, for the horse gets his leverage from the hock to the stifle. Viewed from behind, the hind legs should be closely laced together from top and bottom. The reason for this is quite obvious; when the horse is straining under a load, the closer the legs are to each other the better control he is able to exert over them. Again, the animal with the hocks low down and open behind will lose control to the extent that he will screw his hind feet on the road surface. There is nothing more destructive to the joints than this unsightly action.

The back should be short and level, the ribs should spring out from the backbone. The chest deep, the back rib well let down, making the top and bottom lines level. This is very important, for the digestive organs are located here, and it gives to the mare foal-carrying capacity. Without depth of rib, the brood mare cannot be a success, as it is not so much the height of the mare as the depth of body that constitutes her a brood mare. In going through their pacings, viewed from the side, both ends should move in unison. From the front, the legs should be carried close together, straight and true.

SOME NOTES ON THE BREEDING GROUNDS OF THE PLAGUE GRASSHOPPERS IN SOUTH AUSTRALIA.

[By H. G. Andrewartha, M.Agr.Sc. (Waite Agricultural Research Institute, University of Adelaide).]

In connection with investigations on grasshoppers, the writer visited two regions in the pastoral country during December and January in order to make a preliminary survey of the possible breeding areas of the plague grasshoppers. Grasshoppers were collected throughout the journeys, with the particular object of determining the distribution and prevalence of the locust, *Chortoicetes terminifera* Walk. Other species of less economic importance were collected. Certain of the observations are noted here for future records.

The first trip occupied from 2nd to 18th December inclusive, during which time a traverse of the north-eastern pastoral areas was made, 1,230 miles being travelled altogether. The route (see map) was as follows:—From Yunta to Panaramattee, McCoy's Well, Melton, Koonamore, Curnamona, Koonamore, Waukaringa, Yunta, Winninnie, Manna Hill, Outalpa, Bulloo Creek, Broken Hill, Cockburn, Mutooroo, Lilydale, and back to Adelaide *via* Braemar, Kia Ora, and Burra.

Chortoicetes was first found at Melton. From there on, it occurred throughout the whole of this area. In three places, small swarms were discovered, two on Melton Station and one on Kia Ora Station. Elsewhere, non-gregarious individuals occurred, usually in small numbers, and generally in very localised situations. The presence of grasses (of various species) appeared to be an important feature of most of the habitats carrying *Chortoicetes*. These habitats were generally associated with creek beds or low-lying areas (known in this country as "swamps"); occasionally the species was found on hillsides or flats. Although *Chortoicetes* was found in habitats which apparently contained no grass, it never occurred in the bluebush (*Kochia*) saltbush (*Atriplex*) complex which occupies extensive areas in this country. Details of the samples of grasshoppers collected are given in Table 1, which should be studied in conjunction with the map (Fig. 1). The Table gives the results of collections made in 19 different localities. Many other areas were examined, but only those on which grasshoppers were found are recorded in the table. Altogether, 268 Acridids were collected (exclusive of those taken from swarms); of these, 25 were *Chortoicetes terminifera* and 117 were *Austroicetes* sp. The former species was represented in 8 out of 16 collections, the latter in 11 out of 16; the two species occurred together in 6 out of the 16 habitats represented in the table.

The discovery of swarms was of interest. The one found on location No. 5 occupied less than one acre; the insects were adults loosely congregating together. Their earlier history is not known; presumably they had developed from eggs laid in that vicinity by a swarm forming part of the outbreak of the previous year. If so, these adults probably correspond to "phase dissocians" of writers on other locusts. They were living on the banks of a well-defined, narrow watercourse, which were covered with a good stand of *Stipa*. The small band of gregarious nymphs found on location No. 6 were in the bed of a very shallow wide creek in which the vegetation was mostly *Bassia*. They were migrating at the time of the observations; it is not certain that they were feeding or had been feeding on the *Bassia*. The third swarm, found on Kia Ora (location 19) was more extensive. The area was a gently sloping hillside leading down to a wide but well-defined creek bed. *Chortoicetes* were present over about 10 acres. On the banks there were several small loose swarms of adults and nymphs. Many of the nymphs were undergoing transformation to the adult. In the creek bed there were several

TABLE 1.

Location Number (See Map).	Locality.	Date.	Number of Grasshoppers.				Description of Habitat.

13	Manna Hill	Dec. 12th	6	3	2	11	Flat alongside creekbed; mostly *Bassia*, apparently no grass.
14	Outalpa	Dec. 12th	1	8	17	26	Creekbed. Mostly *Eragrostis.*
15	Broken Hill	Dec. 13th	1	—	10	11	Stony hillside. Mostly *Stipa.*
16	Cockburn	Dec. 16th	—	—	2	2	Flat alongside creekbed. Mostly *Stipa* and *Bassia.*
17	Mutooroo	Dec. 17th	6	—	15	21	Moist swamp, supporting fairly dense herbage grasses, *Echium*, &c.
18	Lilydale	Dec. 17th	—	—	9	9	Flat. Mostly *Bassia.*
19	Kia Ora	Dec. 18th	29*	2	—	31	Slope leading into large creekbed. *Stipa, Eragrostis, Sida,* &c.

* Taken from loose swarm of adults. † Taken from small band of gregarious nymphs.

To get out of the high compression engine of your car ALL the POWER that was built into it—and for hauling work that literally wrenches the last ounce of POWER from your truck engine—THIS IS THE FUEL ! It puts behind every piston power stroke a knockless, sustained punch ; the type of POWER you NEED most—and you'll find it in—

Super Plume Ethyl

THE 5-POWER PETROL

READY

FOR MORE JOBS THAN YOUR TRACTOR EVER DID BEFORE

Goodyear Farm Implement Tyres give your tractor a much wider range of utility.

Fitted with these big, soft, cushiony "air-tyres," your tractor can go anywhere—tackle jobs that would laugh at steel wheels — and what's more, do work in high gear that could only be done with steel wheels in low gear.

The results are quicker and better work, more kinds of work, remarkable savings in fuel, oil, labor—and, because of the smoother running, much less depreciation of your tractor.

Yes! *Goodyear Farm Implement Tyres and Wheels are available on Hire Purchase Terms. For full particulars write to the Goodyear Branch (in all capital cities).*

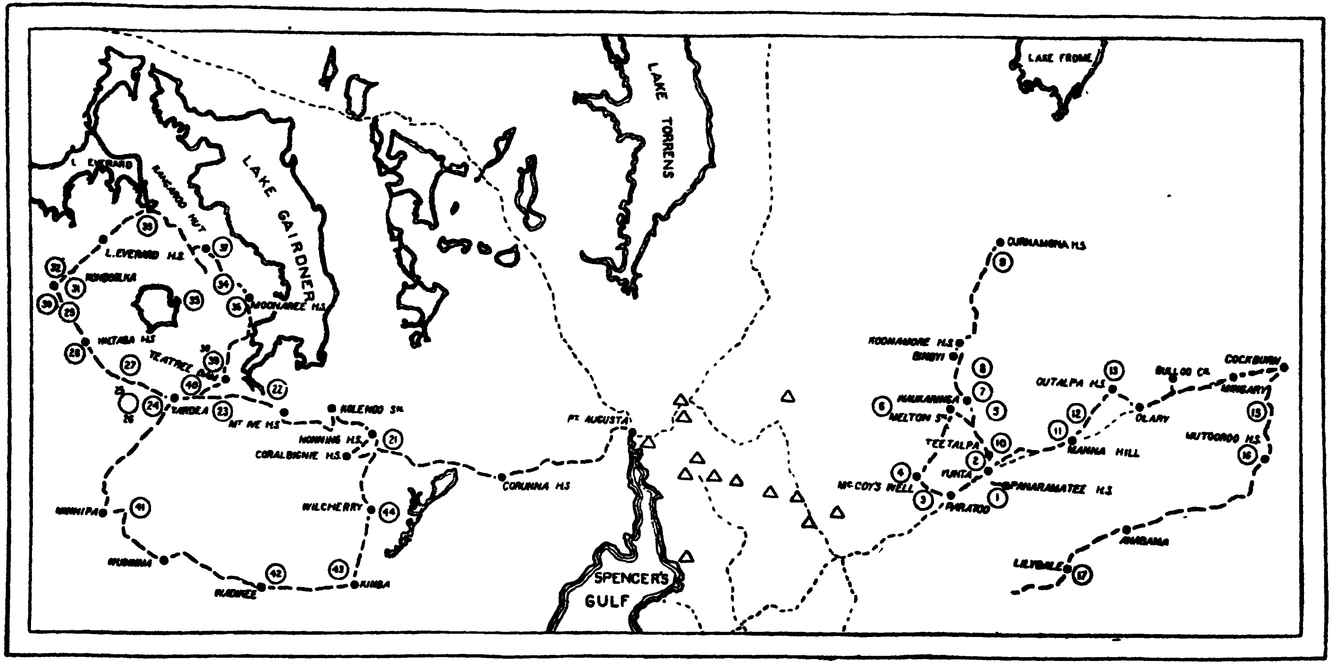
42	Wudinna	Jan. 7th	1	—	5	6	Reverted farm land.
43	Kimba	Jan. 7th	3	—	3	6	Swamp at foot of hill. Mostly grass.
44	Wilcherry	Jan. 8th	1	5	8	14	Large flat creekbed. Grass and *Bassia*.



The heavy broken lines show the routes taken. The light broken lines are the principal railways. Key numbers refer to the localities described in Tables 1 and 2. The triangles represent areas where bands of *Austroicetes* nymphs and adults were observed early in October, 1935; these data have been reproduced from an unpublished report by Mr. D. C. Swan, on a visit to this area in connection with a grasshopper outbreak.

small bands (frequently less than a square chain in area, of gregarious nymphs. Between the gregarious bands nymphs and adults were found thinly scattered about. On the banks, *Stipa* and *Sida* were important. In the creek bed there was a mixed growth, with various grasses predominating. This place was revisited on 15th January. During a diligent search of the area for several miles around, only two *Chortoicetes* were seen. It is probable that the various bands of nymphs had come together to form a swarm of adults which had migrated.

During the second trip, which lasted from 26th December, to 10th January, a traverse was made of the Gawler Ranges pastoral district, and of some of the country immediately to the north and south of it. Altogether, 1,145 miles were covered. This area differed from that seen in the north-east in that there was a greater variety of habitats, and frequently each type of habitat was far more extensive. There were frequently large grassy flats covering many square miles, and equally large areas in which mulga and myall trees and bluebush and saltbush were predominant. The small localised habitats, formed by portions of creek beds and swamps which had been so prominent in the north-east, were not so common in the Gawler Ranges, particularly in that part east of Yardea. For the most part, the large, very level grassy flats which were so typical of the country east of Yardea, carried no grasshoppers. The habitats in which trees (mulga, myall, &c.) and "bush" (bluebush and saltbush, &c.) were dominant carried a few miscellaneous species but no *Chortoicetes*. In the more undulating country in which small ill-defined creek beds or swamps occurred, *Chortoicetes* was frequently found. Also, it was fairly common on the "shooty" areas in the mallee country between Minnipa and Kimba. "Shooty" country is land which has been cleared for wheat and allowed to revert. It is characterised by mallee suckers, *Stipa*, spinifex, and many annual grasses and herbs. In Table 2, details of the various collections are given. It should be studied in conjunction with the map (Fig. 1). Of the 24 habitats represented in the table, 18 of them contained *C. terminifera*, 12 contained *Austroicetes* sp., and in 9 of them both species were found together.

Altogether 234 specimens were collected; of these, 37 were *C. terminifera* and 67 were *Austroicetes* sp.

The history of the recent outbreak in the Gawler Ranges district was fairly clear. Swarms of locusts flew in to the area during the latter part of 1933. Eggs were laid during October and November. These hatched during February and March of 1934; the nymphs became adult, and laid eggs that autumn. These hatched the following August, and became adult in the spring of 1934, migrating in thousands. Thus there were two generations in this country, during the season immediately preceding the peak of the outbreak. It is probable that there were also two generations in the year before that (*i.e.*, 1932-33) in the country further north of the Gawler Ranges, *e.g.*, around Kingoonya.

It must be emphasised that these trips were in the nature of preliminary surveys, and that any conclusions drawn from them can be held only tentatively until further investigations have been conducted. On the evidence now available, there can be no doubt that areas in the Gawler Ranges formed an important intermediate breeding ground during the outbreak of *Chortoicetes*, which reached its climax in the agricultural areas of the western portion of the State during 1934. The permanent breeding grounds from which these swarms originated probably lies further north or further west. The evidence for the north-east pastoral country is not so complete. No evidence is available of autumn generations during 1933. These may have occurred. Most observers are agreed that swarms fly in from the north. Nevertheless, from the available evidence, it would seem that the north-east pastoral country does form a permanent breeding ground for *C. terminifera*, and that swarms can be initiated there.

BIFORA TESTICULATA D.C.

A NEW WEED IN SOUTH AUSTRALIA.

[W. C. JOHNSTON, R.D.A., District Agricultural Instructor.]

In the course of crop inspection duties and a search for *Romeria* hybrids in a field near Riverton, a peculiar, musty, foetid smell was apparent.

This led to a careful inspection of the plant growth with the result that an unknown white flowered plant was observed, which on being crushed gave off the foetid odour which was noticeable in the atmosphere.

IDENTIFICATION AND PLACE OF ORIGIN.

Specimens were taken and dried and forwarded to Mr. J. M. Black for identification, but owing to the fact that the plant proved to be one of the *Umbelliferae* in which ripe seeds are necessary for examination of the vittas, the identification could not be finalised. Later, ripe seeds were obtained and forwarded to Mr. Black who identified the plant as *Bifora testiculata* D.C.

The species is reported by Coste as belonging to the south of France, Syria, and North Africa and is a typical North African weed.

DESCRIPTION FROM COSTE.

An annual from 20 to 30 cms. (8in. to 12in.) in height, glabrous, strong foetid smelling; stem striate, branching; radical leave pinnatisect with tripartite segments and angular lobes, denticulate; stem leaves bipinnatisect, with divaricate sharp, linear lobes; flowers white, almost regular in umbels of 2 or 3 striate rays; umbellules with 2 or 3 flowers all fertile; involucres and involucels consisting of 1 linear bract; style recurved to level of disc; fruit didymus (two lobed with obtuse lobes) much wrinkled, indented at base and with conical projection at the summit.

ECONOMIC IMPORTANCE AND DISTRIBUTION.

The plant has no economic features of value and it is doubtful whether it is of any importance as a weed. Its habit of growth does not appear to be such as will cause any economic loss, either in cereal crops or pastures. It is certain, however, that the objectionable odour will repel stock from feeding on it, but up to date it has not been recorded under pasture conditions.

At present the weed is known on one farm at Riverton, where it is distributed over a 70 acre field. The population in any one patch never appears to be very great and on land devoted to the cultivation of cereal crops, it is not likely to become very vigorous, certainly not to the extent of being able to compete with any free growing variety of wheat.

The writer desires to record his sincere thanks to Mr. Black for the identification of the weed and also for his ever available assistance in the classification of plants.

MANAGEMENT OF PASTURES.

COMPARING RIVER MURRAY WITH NEW ZEALAND.

[*A large number of settlers on the River Murray Swamp areas attended a Field Day, conducted by the Jervois Branch of the Agricultural Bureau, at Wood's Point, through the courtesy of Messrs. W. H. Morphett & Co., on 20th February. The following address was given by Mr. W. J. Spafford (Deputy Director of Agriculture).*]

New Zealand probably possesses the best pastures in the World, and their general excellence is largely due to the favourable natural conditions obtaining, but is also contributed to by the skilful management by the farmers. Every effort is made to keep the pastures free from weeds and to reduce to a minimum the proportion of coarser pasture plants. Weeds that cannot be grazed down are cut, and the coarser pasture plants are kept under by hard, close grazing at regular intervals.

The best of the pastures consist of well-balanced mixtures of White Clover and Perennial Rye grass, and many of them contain, as well, a noticeable proportion of Rough-stalked Meadow grass; these mixtures are kept as such by careful tending. Neglected pastures, alongside some of the best in the country, contain a mass of White Clover, but instead of having this clover well balanced with Perennial Rye grass and Rough-stalked Meadow grass, they show a luxuriant growth of Cocksfoot, Prairie grass, Red Clover, and even Tall Fescue as well as the other three pasture plants. Many of the under-grazed pastures to be seen contain a dense mass of growth as high as the fences, whereas the properly grazed ones are kept to a few inches in height.

What has become known as rotational grazing is practised, even to the extent of leaving the animals on each field for one day only at a time. On some farms the fields are grazed for one day, then rested for 10 to 14 days in the winter when the pastures are not making strong growth, whereas the same fields are grazed for one day every 4 or 5 days in the spring and summer. This rotational grazing is not practised with the idea of getting more proteinous fodder—this being unnecessary because White Clover is present in plenty—but its prime object is the maintenance of the best pasture plants in correct balance, which can only be done by very hard, close grazing at regular intervals. The grazing for short periods, and spelling the pastures for several days prevents undue fouling, reduces the risk of eating out the best types of plants, and keeps the animals in better health.

Harrowing of pastures to the extent of tearing the plants about is not very popular, but great care is taken to ensure that the droppings of animals are broken and spread about.

Except in the very richest flats of New Zealand, top dressing of the pastures is general, and judged by South Australian practices is liberal. A few proprietary mixed fertilisers are utilised for top-dressing purposes, but it is usual to apply superphosphate, and in many places lime is used as well. Large areas of pastures receive from 3cwts. to 6cwts. of superphosphate per acre per year, and some get as much as 10cwts. of lime per acre per year as well, although this amount is an unusually heavy dressing.

New Zealand farmers appear to fear a too-prolific growth of the strong-growing pasture plants such as Cocksfoot, Red Clover, and Prairie grass, or worse still the appearance in the pastures of Tall Fescue. Every effort is made by the better men to eradicate Tall Fescue, but the other strong-growing plants are kept down so that their stems do not become too coarse. This is done by utilising cattle as well as sheep on the pastures, and by hard, close grazing.

The pastures of New Zealand are grown in small fields where hard, close grazing can be carried out. Care is taken to keep down bad weeds, top-dressing is undertaken in most places, cattle and sheep are maintained on many farms to keep the good pasture plants in correct balance, and the droppings of animals are spread frequently.

Although the climate is hotter, the position as regards pastures on the reclaimed swamps of the River Murray is very similar to that of New Zealand in that the pastures make very strong, luxuriant growth in spring and summer, and because of the irrigation water they remain evergreen. Because of these similarities, it appears certain that the method of management will need to approximate closely that of New Zealand if the pastures on these reclaimed swamps are to give the high grazing returns that they are capable of giving.

When pastures are being established, the good pasture plants only should be used, such as White Clover, Cocksfoot, Perennial Rye grass and Rough-stalked Meadow grass until other more suitable pasture plants have been proved.

Holdings should be closely subdivided. Where 30 cows are being milked no field should exceed 3 acres in extent, so that the necessary hard, close grazing can be done, using 10 cows to the acre for 1 day, or if sheep are used to be able to put 100 sheep per acre for 1 day. Although the necessity for the control of Tall Fescue does not exist on the reclaimed swamps as it does in New Zealand, *Papsalum dilatatum* is spreading rapidly to the exclusion of better grazing plants. Small fields, hard grazing, and the encouragement of clover are essential if this plant is to be kept within reasonable bounds. Couch grass (*Cynodon dactylon*) is also extending, and where this grass is present in quantity, similar good methods of management are essential.

If the pastures are grazed properly, edible weeds will be eradicated. or at all events kept in check, but all non-edible weeds should be removed.

Top-dressing the pastures with superphosphate every year, and with lime occasionally, should be carried out. The good pastures are easily worth from 3cwts. to 5cwts. of superphosphate per acre per year, and the equivalent of 10cwts. of slaked lime every 3 or 4 years. Top-dressing with phosphates and lime is not only necessary to promote full growth of pasture, but is essential if enormous numbers of livestock are to be grazed on these areas for several years in succession to maintain the animals in good health. The constant removal of large amounts of phosphorus and lime in the milk and meat produced by these pastures quickly leads to a shortage, which shows itself in the ill-health of the animals, lessened growth of young stock, and lowered returns from all animals being grazed.

Cattle and sheep should be maintained on the holdings to keep the pastures in the best of condition. Where cattle are the chief activity, some sheep should also be carried, and where sheep have pride of place, some cattle, perhaps beef cattle, should be fattened.

The droppings of animals should be spread about the fields fairly frequently, using for the purpose light harrows or some such contraption as a piece of cyclone fencing weighted with timber on the back edge. Where twitch grasses, such as Couch grass (*Cynodon dactylon*) and Water Couch (*Paspalum distichum*) are present, or where *Paspalum dilatatum* has a hold, harrowing with an implement heavy enough to tear the sod will do much good.

GREEN MANURING.

[By N. R. QUINN (Assistant Horticultural Instructor).]

The growth of green crops and their incorporation with soil as green manure are not a new practice; the ancient Romans found that by preliminary ploughing under of leguminous crops, the succeeding main crops benefitted considerably. It is well known that in the case of a virgin soil, carrying a natural cover of grass, the organic matter or humus content of the soil is maintained at a more or less constant level. It is also known that when such a soil is ploughed and cultivated over a period of years, large quantities of organic matter are lost; sandy soils are probably more subject to such humus depletion than are heavy soils.

The loss of organic matter interferes with the physical condition of a soil, and and it will be noticed after a period of years from the breaking of virgin soil, that the soil becomes less tractable. Sandy types of soil become loose and unstable, whilst the heavier clay type soils become hard and relatively impervious to moisture. These physical changes come about through the depletion of the original organic matter, the decomposed vegetable matter or humus having a binding effect on a sandy soil, and an ameliorating action on the fine particles of a clay soil.

With the decomposition of vegetable matter in a soil, weak humid acids are formed, and these acids, reacting on the fixed mineral plant foods in the soil assist in transforming such fixed unavailable plant foods into forms which the growing crops can readily assimilate. Under certain specific conditions, particularly in the United States of America, it is sometimes customary to maintain orchards in sod, but under Australian conditions, where rainfall may be an important limiting factor to growth and cropping, this system of fruit tree culture is not always desirable. Furthermore, the minute bacteria that inhabit the soil, and transform decaying vegetable matter into plant foods, require light and air, and to provide them with these essentials some cultivation is necessary.

Apart from consideration of the effect of green cropping on soil texture and the supply of plant food, there are other beneficial effects to be derived from the practice, viz.:—

(1) The prevention of soil erosion on a hillside during heavy winter rains. It will be found that a growing green crop sown across a slope as far as practicable will retard the rush of surface water.

(2) In many orchards a high water table may exist during the winter months, and in such instances this very undesirable condition may be reduced to a considerable extent by planting a green manure crop over the affected area. The volume of water transpired by a winter growing green crop is enormous, and from this viewpoint such a crop may be regarded as an excellent drainage system.

There are many kinds of plants which the orchardist may use for green cropping. Generally, the legumes should be given first preference, beans and peas being most commonly used. The chief advantage of leguminous green crops lies in their well-known capacity of fixing atmospheric nitrogen. One other advantage the legume has over the non-legume is that the former generally goes through the process of decomposition more readily when ploughed under.

The non-legumes that are popular for sowing as green crops are barley and rye. These two cereals have not the capacity of adding to the soil's nitrogen supply from the air, as is the case with legumes, but if the seed is sown thickly, a large bulk of organic matter for ploughing under will be provided. It should be borne in mind that early sowing of a green crop is essential; often the harvesting of the main orchard crop will not have been completed at the optimum planting time, and under such circumstances, the best practice is to green crop in alternate lanes in alternate years, thus eliminating undue interference with harvesting operations.

The soil in a well cultivated orchard requires very little preparation prior to sowing of a green crop. The usual method is first to loosen the soil, with the orchard cultivator, in the rows to be sown. The seed may be broadcast, and generally superphosphate is applied with it. Amongst trees of a spreading nature the orthodox seed drill approaches closely to the trees with difficulty, and the result is that only a narrow strip in the centre of each row is sown. In such cases, it is usual to broadcast 2cwts. of superphosphate to each actual acre to be sown, and then to broadcast 80lbs. of tick beans or 70lbs. of peas per acre and cover by light harrowing. The green crop should be sown, if possible, at the end of February or in early March, and this early sowing may not be practicable in the case of the legume without the help of an irrigation. Barley sown at the rate of 60lbs. per acre will be found to be a suitable crop under relatively dry conditions.

The reason for sowing early is to make it possible for the crop to produce as much growth as possible before the soil becomes too cold, for it is necessary to plough the crop under some time before bud-burst of the fruit trees or vines. In the case of a leguminous crop it has been found that there is an interval of from three to five weeks after turning under of a green crop before nitrogen becomes available as plant food. During the period of decomposition of a green crop, there is a definite deficiency of available nitrogen in the soil, and if the crop has, of necessity, been turned under late, it is advisable to add some artificial nitrogen to accommodate the demands of the main fruit crop during this period. Leguminous crops respond very noticeably to a preliminary dressing of lime on soils that are inclined to be sour.

Usually, when a leguminous crop begins to flower, ploughing under has been deferred a little too long, and further, under dry conditions, the green crop has been permitted to dry out the soil, very often to the disadvantage of the fruit trees and at the expense of ready decomposition of the green crop. A green crop ploughed under in a dry soil may do harm in that it will cause the soil to be kept too open, with consequent rapid loss of soil moisture reserves.

The advantage of early sowing of a green crop in orchards that are heavily clothed with "soursob" during the winter months will be appreciated, as the crop will probably have made good growth during the warmer months, and later be in a position to withstand the competition of soursob.

There are two main methods of turning under the green manure crop:—(1) The crop may be rolled down and then disced under. This method is usually practised when it is not possible to plough very deeply. (2) When the soil is deep and of a friable nature the mouldboard plough is the best implement to use.

The usual practice is to use a single-furrow plough with a disc coulter attached and a drag chain slung from the "off-side" swing bar back on to the beam of the plough; some slack is permitted in the chain to catch the crop and drag it into the furrow.

Green manuring is a practice that should be carried out regularly, as it takes years to build up a soil that has become deficient in organic matter. At first, the benefit may not be readily appreciated, but after a few years of regular green cropping the improvement in soil fertility will usually become so marked as to convince even the complete disbelievers.

A BRITISH tractor fuel of proved EFFICIENCY!

Buy from Britain and assure a market for your own primary products. Use "C.O.R" Power Kerosene . . . it is British-Australian and gives acres per gallon unsurpassed by any other tractor fuel.

Obtainable in convenient 24-gallon drums.

"C.O.R"

NEW PROCESS

PK14/A

POWER KEROSENE

The Commonwealth Oil Refineries Limited. (Commonwealth Government & Anglo-Persian Oil Co. Ltd.)

ESA BLUESTONE

MANUFACTURED BY

THE ELECTROLYTIC REFINING AND SMELTING COMPANY OF AUSTRALIA LIMITED, PORT KEMBLA, N.S.W.

Guaranteed to contain not less than 99% Sulphate of Copper.

USE IT— In preparation of Spray Mixtures for Fruit Trees and Vines.
For Treatment of Foot-rot in Sheep. For Wheat Pickling.

Agents for all States:

ELDER SMITH & Co., Limited. All Capital Cities.

Write for Booklet—"Better Yields by Spraying with ESA Bluestone."

There is only One Best SEPARATOR

THE

"ALFA LAVAL"

Holds the World's Record for Clean Skimming

Rustless Metal Bowl and Discs.

AWARDED FIRST PRIZE
Royal Agricultural Society's Show, 1935.

Allowance made for old Separator, and balance on easy terms.

A. W. SANDFORD & Co., Limited,
Grenfell Street, Adelaide.

It is to the interest of every Farmer to belong to the AGRICULTURAL BUREAU.

Join the nearest Branch, or if you are not within driving distance of the nearest branch write to the General Secretary, Central Agricultural Bureau, for particulars as to how to form a Branch.

WOMEN interested in Agriculture should join a Woman's Branch. Full particulars on application.

TRAVEL SERVICE.

A Commonwealth Savings Bank pass-book disposes of all the money worries that usually trouble the traveller.

Money can be transferred to any point, and withdrawn or deposited at any one of the Bank's 4,000 Branches and Agencies without cost.

Ensure the utmost convenience and safety by travelling, not with a dangerously large amount of money in your pocket, but with just your pass-book to see you through.

Commonwealth Savings Bank of Australia

(Guaranteed by the Commonwealth Government.)

SALT PATCHES OF LAND IN DISTRICTS OF HIGH RAINFALL.

A member of the Mount Compass Branch of the Agricultural Bureau has referred the following question to the Department of Agriculture:—"I have always been under the impression that salt patches in wheat-growing country were caused by evaporation of soil moisture in years of low rainfall and disappeared in years when rainfall was higher than usual. From my observation, this has been my experience. If this is so, why should there be salt patches in the Mount Compass district, which has a rainfall of about 30in. or more?"

Replying to the question, Professor A. J. Perkins (Director of Agriculture) says:—

"On general principles it would be incorrect to state that causal factors leading to the formation of salt patches in wheat country of about 12in. of rain were confined to evaporation of soil moisture in years of low rainfall. The question is far more complicated than that, and depends much upon local conditions and factors, of which moisture conditions are one, but not the only one. It has frequently been noted that in some districts salt patches often developed after years of unusually heavy rainfall, and the probable explanation was that the country in question was mildly impregnated with saline matter to several feet in depth; that in years of exceptional rainfall the

surface moisture penetrated to greater depths than usual, and came in contact with hitherto untapped saline layers of soil; that in succeeding years some of this saline matter rose to the surface, under the influence of surface evaporation, giving rise to salt patches, which might subsequently be dispersed by sufficiently heavy winter rains. Sometimes it was a question of the relative slope of underground more or less impervious soil layers, which tend to lead water impregnated with salt to accessible lower levels.

Although not acquainted with the Mount Compass salt patches, the Director points out that the saline matter need not necessarily have originated at Mount Compass itself; it might easily have been conveyed to the district from a distance by means of running water, either underground or surface.

Again, the salt might be derived from the decomposition of local rock, the salt water seeping along lines of cleavage, and frequently finding an outlet along sloping hills.

Moreover, because Mount Compass has a heavy rainfall to-day, it does not follow that this has been so throughout earlier geological periods. The foundations of the salt trouble may date back to a very distant period, and if it be present in the district, heavy rains will tend gradually to distribute it; but unless there was a completely adequate natural outlet to the sea, some of the salt would re-appear from time to time in the shape of salt patches of permanent or temporary character.

BLACK PIECES IN DRIED APRICOTS.

[A. G. STRICKLAND, M.Sc. (Chief Horticultural Instructor).]

Reporting that during the past drying season that the percentage of black pieces in dried apricots showed a considerable increase over previous years, and that growers were definite in their statement that when the fruit was cleared from the trays there were no black pieces placed in the sweat boxes, the Secretary of the Ramco Branch of the Agricultural Bureau has asked for an explanation of this trouble from the Department of Agriculture.

Mr. Strickland says:—The chemical mechanism of darkening of various fruits at cut surfaces differs somewhat according to the type of fruit concerned, but invariably the action is one of oxidation of one or more substances in the plant tissue. The course of this oxidation, by which coloured substances are formed, is assisted by various enzymes which are naturally present in the fruit; if such "enzymes" are killed or inhibited, the oxidation process moves slowly enough to enable drying of the cut fruits before appreciable discolouration has taken place. Sulphur dioxide is customarily used to inhibit the enzyme action, and enable production of non-discoloured dried fruit.

Exactly why certain individual pieces of apricots should blacken is not definitely known, but such blackening implies that the enzymes have not been completely inhibited (perhaps through insufficient sulphur content of the particular pieces) and/or that, owing to the presence of some moisture, there is opportunity given for some oxidation and consequent discolouration.

Tests carried out by this Department some years ago showed that the higher the sulphur content of the fruit the better the maintenance of bright colour; this is to be expected. Furthermore, it was shown that generally the riper the fruit the higher and more rapid the sulphur impregnation. One would not, therefore, expect riper fruit to exhibit necessarily more darkening than less ripe fruit.

Fruit which is kept moist after drying is more liable to suffer oxidation and consequent darkening.

It is possible that dark pieces occur owing to insufficient SO_2 content, and it is intended to carry out analyses with the object of gaining information on this particular phase of the problem. The desire to obtain a moist pack also has bearing; if certain individual fruits by some mischance do not get an adequate dosage of sulphur dioxide, and the fruit is then held under moist conditions, these under-sulphured fruits would have favourable conditions for oxidation and darkening.

I quote hereunder a report by Mr. N. S. Fotheringham, Manager of the Berri Experimental Orchard, which report elaborates some of the above points:—

"Considerable work was done here with the sulphuring of apricots some years back. This work was in connection with the sulphur content of apricots, and samples of all tests made were forwarded to Adelaide and kept there for a considerable time for periodical analyses.

"We know that the longer we keep apricots the darker they become, and that light-sulphured fruit will not retain its colour as long as well-sulphured fruit. We also know that unsulphured apricots dry out dark, and soon become almost black.

Until the last few years, the tendency has been to have apricots practically chip dry, but of latter years it has been the desire of the packing houses to pack a moist pack for export purposes, and they have been treating them to make a moist pack.

"Some years ago I remember a parcel of dried apricots coming from South Africa. These were moist packed, and the whole lot went coal black in a very short time. The SO_2 content of them I do not know. It appears to me to be possibly a combination of moisture and light sulphuring that tends to accelerate blackening.

"Moisture seems necessary for this action to take place, and I think that apricots under sulphured, and their colour not fixed, when they become moist undergo this action, and become dark. The action may possibly be hastened by being sweated in sweat boxes when too moist."

VACCINATION EXPERIMENTS WITH ENTERO-TOXAEMIA VACCINE AT KYBYBOLITE, 1935.

[L. J. Cook, Manager, Kybybolite Experimental Farm.]

Half of the sheep on the Farm were vaccinated this year with Entero-Toxaemia Vaccine. Each flock was divided evenly according to age and development, one half being vaccinated, and the other half maintained as controls. One hundred and ninety-one in-lamb ewes, and 219 hoggets were treated on 4th/5th June, and 1st/2nd July. Two hundred and fifty-two ewes with lambs at foot, and 202 lambs were treated on 13th/14th August, and 9th/10th September.

Amongst the six flocks vaccinated in June and July, 8 deaths have occurred up to 1st January, 1936, and of these 4 were classed as having symptoms suspicious of Entero-Toxaemia. The other four definitely did not show any signs of this disease. The four former cases all occurred amongst the controls of the flocks with details as follows:—

1. 1934 Comeback ewe hogget, grazing on topdressed natural pastures, died on 28th August. Sample of ingesta from small intestine forwarded to Stock Department 28/8/35.
2. 1933 Comeback ewe, grazing on topdressed natural pasture died on 14th September. Sample of ingesta forwarded 16/8/35.
3. 1928 Comeback ewe, grazing on topdressed natural pasture died 10th October. Died in woolshed over night. No sample collected.
4. 1930 Comeback ewe, grazing on Subterranean Clover, and annual grass pasture died 18th October. Also died in woolshed over night. No sample taken.

Summary; amongst the 191 ewes inoculated before lambing in June and July, no deaths occurred that possessed any symptoms of Entero-Toxaemia, whilst amongst 191 similar ewes used as controls, three deaths occurred, that appeared to be caused by Entero-Toxaemia. Also, amongst 219 hoggets innoculated at the same time, only one death occurred, and that possessed no symptoms of the disease, whilst amongst 219 similar hoggets used as controls, one death occurred with suspicious symptoms of Entero-Toxaemia.

Amongst the three flocks of ewes and lambs treated in August and September, 19 ewes and 14 lambs died between 16th August, 1935, and 1st January, 1936. The two flocks of Comeback ewes in this group suffered from a fair amount of foot trouble during the period, and of the deaths, only 8 ewes and 6 lambs showed symptoms of Entero-Toxaemia. Of these, only two ewes were vaccinated, the other six and the six lambs being all amongst the controls in the flocks. The former cases were both dry ewes, and died on the 18th August, five days after the first injection of vaccine was given. One was an English Leicester stud ewe (1933 drop), and the other a Comeback ewe (1932 drop).

The six deaths of ewes amongst the controls occurred as follows:—

1. English Leicester ewe, 1932 drop, with lamb at foot, died on 28th August. Sample of ingesta forwarded to Chief Inspector of Stock 28/8/35.
2. Comeback ewe died at sheep yards on 9th September. Sample ingesta forwarded 9/9/35.
3. Full mouthed Comeback ewe died on 20th September. Sample of ingesta forwarded 20/9/35.
4. English Leicester dry ewe, 1933 drop, died on 27th November with suspicious symptoms of Entero-Toxaemia.
5. Old English Leicester dry ewe, 1926 drop, also died on 27th November with doubtful symptoms of Entero-Toxaemia. This ewe was very fat, and death may have been influenced by hot weather.
6. Full-mouthed Comeback ewe died on 2nd December with doubtful symptoms of the disease.

Regarding the six deaths of lambs amongst the controls, particulars are as follows:—

1. English Leicester stud lamb in good condition died in the woolshed on 7th September with suspicious symptoms, but no sample could be obtained.
2. Comeback x English Leicester lamb died in the field on 9th September, but no sample could be obtained.
3. Two Comeback x Dorset Horn lambs in very good condition died on 14th October with apparent typical symptoms of Entero-Toxaemia, but carcasses were found too late for sampling.
5. Comeback x Suffolk good conditioned lamb died in field on 7th November, also with very suspicious symptoms.
6. Comeback x Dorset Horn good conditioned lamb died in the field on 9th November. Sample forwarded 9/11/35.

Summary; amongst the 252 ewes vaccinated in August, two deaths occurred before the second vaccination was given, but no deaths suspicious of Entero-Toxaemia occurred afterwards. Whilst amongst the 252 similar ewes used as controls, six deaths occurred that appeared to be caused by Entero-Toxaemia.

Also, amongst the 202 lambs vaccinated, no deaths occurred that could be attributed to this disease, whilst amongst the 202 similar lambs used as controls, six deaths occurred with symptoms very typical of the disease.

Finally, amongst the whole 864 sheep vaccinated, 11 deaths have occurred, of which only two could be attributed to Entero-Toxaemia, and amongst the 864 control sheep not vaccinated, 30 deaths occurred, of which 16 could be attributed to Entero-Toxaemia.

It is perhaps unfortunate that the analyses of the six samples of ingesta forwarded to the Stock Department did not throw any definite light on the identifying of the bacteria, but it is considered that the vaccinations have saved a certain loss of stock. The assistance given by the Veterinary Officers was much appreciated.

VACCINATION OF SHEEP—ENTERO-TOXAEMIA—KYBYBOLITE EXPERIMENTAL FARM, 1935-36.

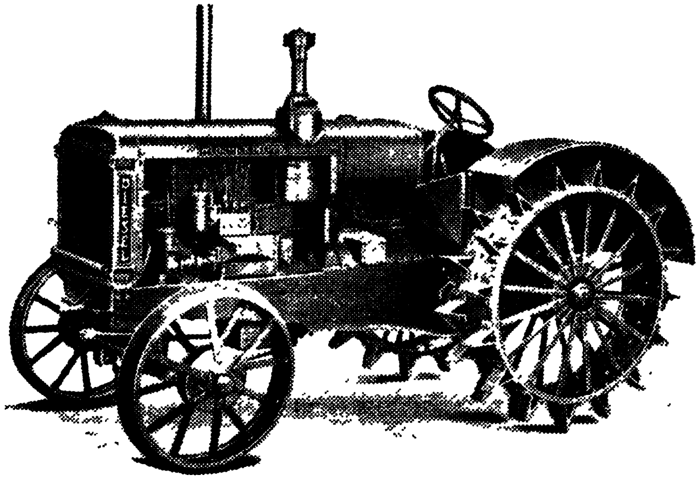
The PINNACLE *of* TRACTOR *ECONOMY*



McCORMICK-DEERING WD-40 DIESEL-POWERED WHEEL TRACTOR

This new wheel type tractor of the McCormick-Deering line brings you low-cost Diesel power plus all the quality that 30 years of practical experience has developed in tractor design. Generous use of ball and roller bearings, oil seals and high-grade alloy steels reduces wear to a minimum. The special McCormick-Deering engine starts on petrol with ease and certainty in all weathers . . . transfers automatically to Diesel fuel operation. See the McCormick-Deering WD-40 wheel type Diesel tractor – a revelation in modern tractor power—TD-40 TracTrac-Tor is the Diesel-type crawler tractor of the McCormick-Deering line.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE OF LOWER NORTH BRANCHES.

The Conference of Lower North Branches of the Agricultural Bureau, held at Owen on 27th February, ushered in the first of the 1936 series of Conferences that are held each year under the auspices of the Agricultural Bureau of South Australia.

Delegates were present from most Branches in the district.

Mr. A. N. Freebairn, Chairman of the Owen Branch, presided, and the gathering was declared open by Mr. F. Coleman, of the Advisory Board of Agriculture.

The following papers were read and discussed:—"The Diesel Engine," Mr. F. W. Coleman (Saddleworth); "Fencing," Mr. A. Muegge (Rosedale); "Care of Sheep on the Farm," Mr. B. Moldenhauer (Whitwarta).

The agenda contained a large number of questions covering a very wide range of agricultural and livestock topics, which were answered by officers of the Department of Agriculture, including Mr. W. J. Spafford (Deputy Director of Agriculture), Mr. R. C. Scott (Supervisor of Experimental Work), and Mr. H. B. Barlow (Chief Dairy Instructor).

Conference accepted the invitation of the Wasleys Branch to hold the 1937 gathering in that town.

It was decided on the motion of Mr. E. Day (Wasleys), seconded by Mr. W. Hucks (Buchanan): "That when a crop is grown on the share system the following provisions in relation to prizes shall apply:—A joint entry may be made and any prize won to be divided between the owner-farmer and the share-farmer, unless either party refuses to share in the cost of entry, when the entry may be made separately by the owner-farmer or share-farmer, any prize to go to the party making the entry."

The evening session was occupied by an address illustrated with lantern slides, "A Tour of the Southern Hemisphere," by Mr. Spafford.

CONFERENCE OF YORKE PENINSULA BRANCHES.

ARTHURTON, 4th MARCH.

District Conferences of the Agricultural Bureau have been held for many years past at various centres on Yorke Peninsula, and, despite the fact that the Branch at Arthurton is one of the oldest Branches of the Bureau, this year was the first occasion on which it has sponsored a District Conference.

Under the supervision of an energetic Committee, and Mr. T. H. Howlett, the Secretary of the Branch, the Conference was one of the most successful that has been held on the Peninsula.

Mr. J. J. Hentschke, Chairman of the Arthurton Branch, presided, the opening address being delivered by Mr. F. Coleman (Member of the Advisory Board of Agriculture).

In addition to a large number of questions, which were answered by Officers of the Department of Agriculture, the following papers were read and discussed:—

"Improvement of Pastures," Mr. A. B. Ferguson (Arthurton); "Experience in Growing Peas," Mr. H. J. Cadd (Arthurton); "Destruction of Blowflies," Mr. L. Ford (Arthurton); "Horse Dipping," Mr. S. Pontifex (Paskeville).

Mr. F. Coleman presented the trophies to the successful competitors in the Northern Yorke Peninsula Crop Competition.

It was decided "That the 1937 Conference should be held at Stansbury on the third Wednesday in March."

"That any powder, &c., offered for sale for sheep dipping be compelled to conform to a Government standard." The General Secretary, at the request of the Conference, promised to publish a list of the sheep dips approved by the Stock and Brands Department in the *Journal of Agriculture.* "That this Conference recommends that in future any person or persons convicted of stealing wheat or other farm produce be more severely dealt with."

In the evening Mr. Spafford gave an illustrated address on "A Tour of the Southern Hemisphere."

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held at the Blackwood Experimental Orchard on 26th February, there being present:—Hon. A. L. McEwin, M.L.C. (Chairman), R. H. Martin, H. N. Wicks, A. J. A. Koch, F. Coleman, P. J. Baily, S. Shepherd, Dr. A. E. V. Richardson, and H. C. Pritchard (Secretary). Apologies were received from Messrs. G. Jeffrey, A. M. Dawkins, A. J. Cooke, J. B. Murdoch, J. W. Sandford, and Professor A. J. Perkins.

Life Members.—In recognition of 20 years' active membership the honour of Life Membership was conferred on Messrs. F. H. Wolf and G. C. Hienjus, of the Rosedale Branch, and H. A. Eckert (jun.), of Belvidere.

New Branch.—Approval was given to the formation of a Women's Branch at Yandiah, the following ladies being enrolled as foundation members:—Mesdames A. J. Kupke, W. C. Jettner, T. Giddings, E. C. Miechael, A. H. and S. R. Keller, B. H. and A. E. Borgas, D. Stirling, H. R. Neale, R. Llewellyn, and Misses V. and R. Keller and E. Sizer.

Conditional approval was granted for Branches to be formed at Cambrai and Echunga (Women's) with conditional re-organisation of the Meadows Branch.

New Members—The following names were added to the rolls of existing Branches:—Arthurton—Ed. Palin; Beetaloo Valley Women's—Miss Ida Pearce, Miss J. Halse; Belvidere—Glen W. McMillan, John Geo. McMillan, Geo. Brumfield; Coonawarra—Jas. L. Redman, Wm. Davis; Coonawarra Women's—Mrs. — Kamprod, Miss J. Brokensha; Currency Creek—Douglas J. Fergusson; Dudley—H. E. Wood, W. Blight, G. Mayfield, R. Blight; Ironbank—L. Clough, — Nottage, H. Henwood, Reuben Coates, T. Morgan, V. Morgan, A. Morgan, H. Morgan, L. Morgan; Karte Women's—Miss Audrey Trowbridge; Koolunga—Fredk. Reichelt, Glen B. Jones; Koonunga—Herbt. L. Heppner; Kybybolite—D. H. Irving; Lone Pine—Mick Madigan, Colin Lehmann; Mangalo—P. Briese, F. Munday; McLaren Flat Women's—Mrs. G. Hobbs; Mount Barker—A. E. Langrehr; O'Loughlin—Pastor A. Mueller, H. Gaden, R. Linke, T. W. Hedger; Penola Women's—Mrs. F. Fowler; Pinbong—L. A. Scholz, J. Guidera, E. C. Kemmerman, N. O. George; Redhill—Frank Simpson; Rosedale—Frank Noske, Harold Mather; Truro—H. K. Newell; Wasleys Women's—Miss P. Richter, Miss M. Perry, Miss J. Perry, Miss H. Perry, Mrs. H. G. Hancock, Mrs. W. Matters, Miss M. Matters, Mrs. G. Bahr.

Under the direction of the Chief Horticultural Instructor (Mr. A. G. Strickland) and the Manager (Mr. R. Fowler) members inspected the orchard and afterwards visited the packing shed of the Sturt Producers' Society, Ltd.

Several items were taken in Committee.

PAPERS READ AT CONFERENCES.

LOWER NORTH BRANCHES, OWEN, 27th FEBRUARY, 1936.

CARE OF SHEEP ON THE FARM.

[B. R. MOLDENHAUER, Whitwarta.]

One of the first and most essential things to consider in dealing with the care of sheep is the fodder problem, and with this is wrapped up the question of the carrying capacity of a farm. Conditions on different farms vary considerably, so that where one farm could carry a certain number of sheep another not far distant may be able to carry twice as many on the same acreage. Early-sown crops, such as barley or oats, help materially in the carrying capacity of a farm, and prove of great benefit for fattening lambs and keeping the ewes in good condition. But the farmer has to rely mainly on the knowledge he has of the state of affairs on his individual farm, and to regulate the size of his flock to the best of his judgment, bearing in mind that it is far better to be a little understocked than overstocked. Sheep that are being fed on land that is overstocked will not give the best returns as regards wool, or be in the best condition for rearing lambs.

The flock should have access to water all the year round, although during winter they may not require so much as in summer and could probably do without for a fairly long period, it is best to have it available so that sheep can get a drink at any time. The troughs should be of such a height that lambs can drink, and the troughs cleaned out occasionally. Clean water and plenty of feed are two essentials in raising or caring for sheep to get the best out of them.

Be careful when changing sheep into a different paddock after a rain at certain times during the year if stinkwort or clover is present. Milkweed is another plant which is very dangerous; especially if sheep are hungry and are turned into a fresh paddock.

Ewes in lamb or ewes with lambs should have the best feed so that the ewe will have the best chance to rear her lamb.

Crutch the sheep and clip the wool from their eyes if necessary. Young sheep especially are inclined to get wool blind, and if the wool is not clipped from their eyes they gradually fall away in condition, and if they have lambs they cannot look after them properly. Many ewes will not take their lambs for this very reason. Ewes should be crutched a while before lambing; this greatly reduces the possibility of the sheep being struck by flies, and the lamb is able to get a drink when born.

Uncrutched sheep get in a terrible state when greenfeed is young and sappy, and give flies every chance to wreak havoc with the sheep later on as well as spoiling a lot of fleece wool.

The blowfly is a pest that gives the sheepfarmer a fair amount of trouble at times during the year, and although sheep may be crutched it is necessary to go around the flock frequently to keep a sharp lookout for trouble of this kind, and treat the sheep affected with an effective solution that does not mat the wool.

At lambing time the ewes should not be disturbed too much, but kept under fairly close observation, and assistance rendered if necessary.

Shearing time is a period when sheep pass through a sudden change in the warmth of their coats, and if machines are used and one is unfortunate enough to experience wet and cold weather the sheep when shorn should be put where they can get most shelter. If at all possible a good plan is to shed them by night for two or three nights until conditions are better and the sheep become more accustomed to the cold. Late shearing has a disadvantage in that grass seeds are liable to get into the fleece, and not only spoil the wool, but irritate the sheep so that it will not do well.

Sheep should be dipped fairly soon after shearing. A little care and attention to sheep will be repaid by better all-round returns.

[Papers Read at Conferences.]

FENCING.

[A. MUEGGE, Rosedale.]

Unfortunately for the farmer there is always much necessary expenditure he has to indulge in to keep his property in working order. Not the least of these is fencing. The landowner who takes pride in his property at all will endeavour to erect suitable fences. Good fences not only keep the stock within the right side of a property, but add to the value of the farm in £ s. d.

A well-constructed fence is cheapest in the long run. The fence that most farmers in this district require is one that is both sheep and cattle proof. This means it has to be of reasonable height and the wires sufficiently close. It is the purpose of this paper to go into the costs of material for the different types and compare one with the other.

The following are only approximate prices, but at the same time they are from up-to-date catalogues of reliable warehouses and dealers:—

Wood posts, at £7 per 100 or 1s. 4½d. each (length, 5ft. 10in. to 6ft.).
Cement posts, £8 15s. per 100 or 1s. 9d. each (6ft. long).
Strainers, according to size, ranging from 3s. 6d. to 5s. each.
Wire, No. 10 gauge, 18s. to £1 per cwt., which is equal to ½ mile in length.
Wire, No. 12½ high tensile, 21s. 6d. cwt. or £1 4s. 6d. per mile.
Barb wire, £3 per mile.
Flat iron standards, £14 15s. per ton, or 585 approximately, 4ft. 6in. in length.
T-iron standards, £15 15s. per ton, or 425 approximately, 4ft. 6in. in length.

Ordinary fence of 1 barb and 5 plain wires with three standards between posts; 10ft. spacing; length, 1 mile; 3ft. 10in. high:—

	£	s.	d.
Wood posts, 124	8	14	0
Strainers, 8	1	10	0
Wire, 5/12½ H.T.	6	2	6
396 standards	9	16	8
Barb wire	3	0	0
Total	£29	3	2

With No. 10 wire in place of 12½ H.T., £3 17s. 6d. extra; with concrete posts instead of wooden posts, £2 5s. extra; total (approx.), £35 5s. 6d.

This fence may not be lamb proof and a little low for unruly cattle; a 7-wire fence with 2 barbs and 5/12½ H.T. wires with cement posts and standards spaced the same as the above fence should make an ideal stock-proof fence, and being fireproof it should stand for many years without repair. The cost for a fence of this description would be approximately £34 16s. per mile.

The fence with wooden droppers finds favour with many, because besides being cheaper should a horse or a cow lean on the fence there are no iron standards to be bent, and the fence will remain straight as before. The cost of the wooden droppers ranges between 18s. to 28s. per 100 according to size and timber, whereas using "star" or "corkscrew" spaced at 15ft.:—

	£	s.	d.
80 posts	5	10	0
264 standards	12	13	0
8 strainers	1	10	0
Total	£19	13	0

(Each "star" or "corkscrew," 11½d.)

The stronger the standards the more space can be had between posts, and it seems a matter of personal opinion which is better, as types such as "star" and "corkscrew" can be placed further apart, but these, of course, are that much dearer, which in turn makes the financial part of the fence about the same, as can be seen in the following example. In the fences that have been discussed posts were spaced at 10ft. using:—

	£	s.	d.
124 posts	8	14	0
396 standards	9	16	8
8 strainers	1	10	0
Total	£20	0	8

Patent fencing (similar to Cyclone) for 1 mile:—

	£	s.	d.
124 wooden posts	8	14	0
8 strainers	1	10	0
1 mile 5-wire patent	16	16	0
124 standards	3	5	6
1 barb	3	0	0
	£33	5	6
Second barb	3	0	0
Extra for concrete posts	2	5	0
6 wires instead of 5	2	17	6
	£41	4	0

With the 6 wires and second barb it should be stock proof, and an ideal fence, more so than the 5 wires, which have been known to let lambs through. The cement posts make it fireproof. Horses have been known to break and tangle this type of fence by pawing with their front feet, but this is rarely seen. This type (Cyclone, &c.) of fence is most assuredly the better fence for pigs, costing £45 per mile. It is much better than pig netting which cannot be strained, and young pigs seem to make holes in it or crawl under it, as it is comparatively weaker than these "patent" fences.

THE DIESEL TRACTOR.

[F. W. Coleman, Saddleworth.]

Before dealing expressly with the Diesel engine, as applied to the agricultural tractor, it is proposed to give a brief description of the working of this engine and trace the history of its progress.

The Diesel engine, also known as the Compression-Ignition (C.I.) engine, differs from the petrol engine in that during the suction stroke the latter draws in a cylinderful of air mixed with petrol, while in the C.I. engine the charge drawn in consists of nothing but air. In both the charge is compressed by the inward stroke of the piston. The higher the degrees of compression the greater the efficiency of the engine.

With the petrol engine the compression is limited because the charge consists of air mixed with fuel, which, when ignited by the spark, detonates if the compression is too great. In the C.I. engine the charge consists of nothing but air, so that the only limit to the degree of compression is the mechanical one of providing for the strain generated by the pressure.

By using anti-knock fuel petrol engines now have compression ratios up to 7 to 1, but the C.I. engine can use ratios up to 17 to 1, consequently the latter is more efficient than a petrol engine.

The principle of the C.I. engine is that the air is compressed to a degree required for spontaneous ignition, then towards the end of the compression stroke a measured quantity of fuel oil is injected into this highly heated compressed air charge where it is instantly ignited and completely burned, providing the fuel oil can be injected in a proper form and state and have sufficient air necessary to burn it. This principle enables low-priced fuels to be used, and with the high thermal efficiency obtained less fuel is consumed per horsepower generated.

Figures show fuel consumption as low as .37lbs. fuel per brake h.p. hour.

HISTORICAL.

Rudolph Diesel was born in Paris in 1858, and was drowned from an Antwerp-Harwich mail steamer on 30th September, 1913. In 1893 the first Diesel engines were built of both four-cycle and two-stroke designs. A compression of 500lbs. was used, and the fuel was injected by a blast giving 1,000lbs. per sq. in. This was efficient but too costly.

Semi-Diesels using a hot bulb or hot spot were then used for a time, but in 1924 Vickers-Petter turned out an engine of 500 h.p. running at the slow speed of 250 r.p.m. Fuel with a flash point of above 150° F. was pumped into a water-cooled chamber. By 1925 all the British marine engine companies were using some Diesel engines. Ships equipped with these engines showed a thermal efficiency of 40 to 45 per cent. over the 20 to 25 per cent. with steam. The fuel bills were found to be about half that of an oil-fired burner for steam. Other advantages in a ship were the saving of space and personnel.

Diesel-Engined Tractor on F. Coleman's Property, Saddleworth.

In 1926 1,000 h.p. engines were being installed in locomotives and rail cars, the drive usually being taken through electric generators. The Diesel engine put in the South Australian rail car gives a mileage of 9.52 m.p.g. against 4.1 when petrol was used on the same run. The Municipal Tramways buses show 10.8 as against 5.7 m.p.g. with petrol and 17.5 against 7 m.p.g. with petrol. The Tramways have saved £230 in 7 months. A 5-ton Albion truck operating on a run of 59 miles from Melbourne used to cost 9s. 6½d. for the run using petrol as fuel, but can now do it for 2s. 0½d. with crude oil. Five-ton trucks running from Mount Gambier to Melbourne run at a fuel cost of ½d. per mile using Diesel engines. Tests in England also show 14 m.p.g. against 8.4 with petrol, or .43d. per mile against 2.1d. A Lagonda car with Diesel engine on a trip through Wales reached speeds up to 83 m.p.h., and averaged 42 m.p.g. of fuel. A Cummins car in 1931 at the Indianapolis Speedway averaged 86 m.p.h. for 500 miles, and was the only car in the race to complete the course without a stop. Capt. Eyston has reached a speed of 120 m.p.h. on another racing track with a Diesel-engined car.

Bus companies' tests have shown that overhauling is necessary only after having done 30,000 miles running. Diesel engines will run for three times as long as petrol ones before decarbonising and valve grinding are necessary. The Birmingham Corporation has over 100 passenger buses equipped with 5 cylinder Gardner Diesel engines.

The main advantages then of the Diesel engine are:—

1. Low running costs.
2. Slow speed engines.
3. High overload capacity.
4. Absence of electrical gear.

The advantages of the Semi-Diesel are that they can be made lighter, and starting is simplified by the use of a heating lamp.

Diesel engines in stationary power units show on a pumping plant that 9,700,000galls. could be pumped for £15, or less than ½d. per 1,000galls., when electric pumps cost 1d. per 1,000galls.; 250 tons of rock was crushed to 1¼in. in 10 hours for 17s. worth of fuel. Diesel-powered refrigerators will make ice for 1s. 6d. per ton. A wide range of fuels can be used, and fuel can be obtained if necessary from brown coal.

DIESEL TRACTORS.

One of the first Diesel tractors to make its appearance in South Australia was the one-wheeled drive, 2 cyl. *Benz*. The engine running at 800 r.p.m. developed 30 h.p.—a powerful tractor using 1½galls. of fuel per hour, but the design was found to be unsatisfactory for South Australian conditions.

This tractor was followed by the *Lanz* Semi-Diesel single cylinder which is started by heating the cylinder head with a lamp. Running at 500 r.p.m. on the two-stroke principle, 30 h.p. is developed at the belt and 15 at the drawbar; 1½ to 1¾galls. per hour of fuel are consumed under load, and lubricating oil was used at the rate of 1gall. per 10-hour day. It gave a drawbar pull of 2,800lbs. The *Imperial*, an Australian-made machine, works on the same principle as the Lanz. It has a large bore (9¼in.), which is ⅜in. more than the Lanz, and develops 36 h.p.

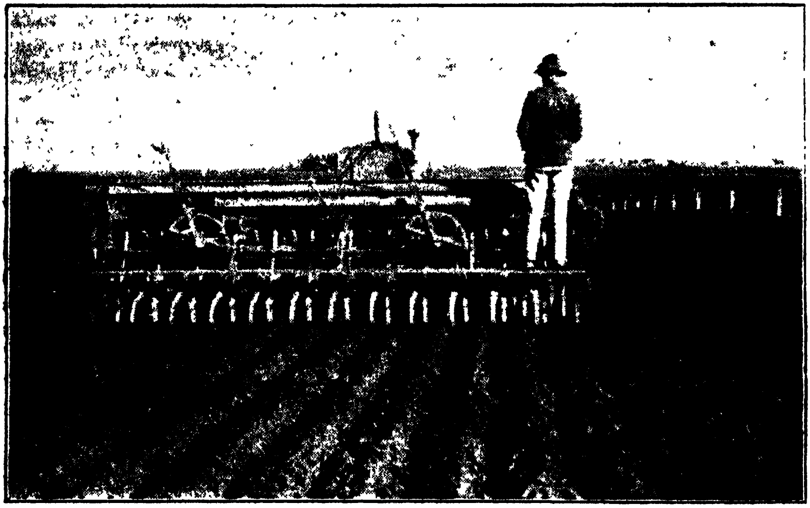
The *Avance*, with a 2-cylinder 2-stroke engine, with an engine speed of 625 r.p.m., was a very powerful tractor. A compressed air cylinder on the machine used in conjunction with a blow lamp made starting easy. This machine had a self-locking differential which prevented slippage on one wheel in soft patches.

The *Benz* then brought out a 4-wheeled tractor with a single cylinder working on the 4-cycle principle. The engine ran at 800 r.p.m., and gave 26 h.p. at the belt. The horsepower at the drawbar, however, was lower than the other makes, and was suitable only for small farms. The initial cost, however, was prohibitive so far as the small farmer was concerned, but the principle of operation was good. It starts from cold, a compression lever being used. Fuel is injected under 900lbs. pressure into the pre-combustion chamber. Under load only 1gall. of fuel is used per hour, and savings up to 75 per cent. in fuel are obtained. This would be the ideal tractor for the small farm if it could be produced at a competitive price.

The *Caterpillar* Tractor Co. produced their first Diesel in 1931, and up till 1st November, 1935, had turned out 9,000 Diesel engines, 7,000 of which are operating in tractors. Four models are now being made by this firm with Diesel engines with drawbar horsepowers of 95, 60, 45, and 35. The three larger models run at low engine speeds, 820 to 850 r.p.m., and are full Diesels with a compression ratio of 14 to 1, and of 4-cycle design. Aluminium alloy pistons with 8 rings each are of the same size for the three models, the "45" being a 3-cylinder engine, the "60" a 4-cylinder, and the "95" a 6-cylinder. The larger models have 6 forward speeds ranging from 1.7 to 5 miles per hour.

The 1934-5 model of 40-46 h.p., now popular in South Australia, has 4 forward speeds, and in low gear (1.7 m.p.h.) has a drawbar pull of 10,400lbs. It weighs 6 tons, and with standard 16in. shoes has a ground pressure of 6.2lbs. per sq. in. Under load the fuel consumption is 1½ to 1¾galls. per hour, and lubricating oil 4¾ pints per 10-hour day. All models use an auxiliary petrol engine for starting, which usually takes about 4 minutes in the morning, using about 1 pint of petrol.

The *McCormick Deering* T40 Tracklayer is of similar power to the Caterpillar 40. At low gear (1.7 m.p.h.) a drawbar pull of 10,900lbs. is given. It is a 4-cylinder 4-cycle engine with a compression ratio of 15 to 1, and travels at 1,100 r.p.m. It weighs 5½ tons, and with 16in. shoes has a ground pressure of 5.4lbs. per sq. in. The starting arrangement is very ingenious, the 4-cylinder motor being converted into a petrol motor by opening a port in the cylinder, thereby lowering the compression ratio and bringing in the spark plugs for firing, all other working parts being common to both engines. After starting on petrol, the change over to Diesel operation is automatic, and is made after a given number of engine revolutions. Auxiliary engines and batteries are thereby eliminated for starting.



The Diesel Tractor hauling a 26-hoe Combine.

The *Cletrac* 40, a 6-cylinder 4-cycle engine of 46 drawbar horsepower, gives a drawbar pull of 9,600lbs. at 1.8 m.p.h. The engine travels at 1,200 r.p.m., and has a compression ratio of 14 to 1. This tractor weighs 5 tons, and with a 15in. shoe has a ground pressure of 5.9lbs. per sq. in. The engine is a standard Hercules Diesel, as is also being used in Diamond T, White, Federal, and G.M.C. trucks. Starting is from cold by means of batteries.

During the last two months two new Diesel tractors have been placed on the South Australian market.

The *McCormick-Deering W.D.* 40 has the same engine as the tracklayer but it propelled by wheels. The advantage in this model is the lower cost price to the user. These sell at between £700 and £800.

The other make which will not be out here until June, 1936, is the *Caterpillar R.D.* 4 of 35 drawbar horsepower. It will be of different design to the 3 larger models, being a 4 cylinder of 4¼in. bore, the "40" having a 5¼in. bore and only 3 cylinders. It will also run at a much higher engine speed, viz., 1,400 r.p.m. The drawbar pull at 1.7 m.p.h. is 8,500lbs., the weight 4¼ tons, and with 13in. shoes has a ground pressure of 5.9lbs. per sq. in. Five forward speeds are provided being 1.7 low, 2.4, 3.7, and 5.4 m.p.h. in high. Price, £850 to £900.

When considering the purchase of a tractor the following points should be borne in mind:—

1. The need for a tractor.—Be satisfied that the tractor will make definite savings in the work to be done.

2. Purchase price.—If heavy continuous work is demanded, long life and low cost of upkeep must take first consideration.

3. Ability to do better work.—A tractor that will not do the work as well or better than the power being used is of no use.

4. Versatility.—It must be able to do all kinds of work demanded.

5. Reliability.—It must be able to carry on with the job when conditions are right. There must be a good backing to the machine, and parts should be available when required.

Horsepower is worked out on the basis that 1 h.p. will lift 33,00lbs. 1ft. in 1 minute. A tractor travelling at 2½ m.p.h. equals 220ft. per minute, so that 40 h.p. equals 1,320,000 ft. lbs. of work. Divide the ft. lbs. by the speed in feet per minute, which gives the lbs. pull—40 h.p. then equals 6,000lbs. pull. The gradient also affects the pull; 1½ per cent. of the total weight of the outfit must be deducted from the effective pull for every 1 per cent. of gradient. Wheel tractors have less parts than the tracklayers. The grips on the wheels, however, offer more resistance to the propulsion of the machine, and less percentage of engine power is made available at the drawbar for pulling. Field tests at Nebraska show that 7 popular makes of wheel tractors gave 70.3 per cent. of power at the drawbar while 7 tracklayers gave an average of 81 per cent. A 1,500lbs. horse walking at 2½ m.p.h. and exerting a pull equal to one-tenth of its own weight gives a pull equal to one drawbar horsepower.

A 2,000lbs. horse would then pull 200lbs. or 1.33 h.p. Petrol and kerosene burning tractors consume about 1lb. of fuel per h.p. hour under rated drawbar load, whereas Diesel tractors use less than ½lb. of fuel per h.p. hour.

OPERATING COSTS.

In conclusion, the following statement shows the working costs of a tractor at Saddleworth for 6 years. In March, 1930, we purchased our first tractor, a petrol-kerosene burning tracklayer of 15-20 h.p. for £470 landed on the farm. After working for 3,436 hours of operating time in 5 years was sold for £280 in 1935.

Costs for 5 years' work were as follows:—

	£		s.	d.	
Fuel, oil, and repairs	449	or	2	7	per hour
Depreciation at 10 per cent. and interest at 5 per cent.	295	or	1	8	per hour
Labour—Operating at 1s. 6d., plus 10 per cent. for overhauling, greasing	283	or	1	7	per hour
	£1,027	or	5	10	per hour

In January, 1935, a 40 h.p. Diesel tracklayer was purchased costing £1,100 delivered at the farm. During the 12 months the tractor has been operating for 1,280 hours, the following farm operations having been performed:—

	Acres.	
Cultivating	1,854	
Seeding with combine	689	
Ploughing	381	
Disc ploughing	134	
Harrowing	1,018	
Pea harvesting	93	
Dam sinking	—	52 hours
Total	4,169	

The costs of operating for the year are as follows:—

	£ s. d.	Per Hour. s. d.
Diesel fuel oil, 1,866galls. at 7¾d.	60 7 0	1 0
Petrol starting, 35galls. at 1s. 6d.	2 13 0	
Engine oil, 70galls. at 5s.	17 10 0	0 6
Gear and track roller oil, 50galls. at 5s. 2d.	13 0 0	
Kerosene for cleaning, 10galls. at 1s.	0 10 0	
Repairs	Nil	estimated 3d.
Depreciation at 10 per cent. on £1,100	110 0 0	2 0
Interest, 3 per cent. on £600 (average depreciation value)	18 0 0	
Labour—Operating at 1s. 6d., plus 10 per cent. for overhauling, greasing, &c.	106 0 0	1 7
	£328 0 0	5 4

A comparison of costs of farm operations with tractor costs only show:—

Operation.	Fuel cost only. Petrol. s. d.	Fuel cost only. Diesel. s. d.	All costs. Petrol. s. d.	All costs. Diesel. s. d.
Ploughing with 5 and 10 furrow ploughs ..	2 0	0 7	6 0	3 0
Cultivating, 9ft. and 14ft. machines	0 11	0 2¼	2 9	1 4
Harrowing, 10 leaves, 33ft.	0 2	0 0¾	0 7	0 4
Pea harvesting, 6ft.	1 9	0 8	5 8	5 0

The actual savings made on the farm by the 15-20 h.p. petrol tractor for the 5 years was £379. In 1930 and 1931 18 horses were sold for £149. The cost of keeping them for the 5 years was £144 per annum. Costs per horse at £8 made up as follows:—4 tons of chaff and hay at 30s. = £6; grazing at £1, and stabling at £1 per head. The wages for an extra man 9 months at £12 per month, £108 per annum, was also saved for 4 years. Total savings:—Sale of horses, £149; upkeep of horses, £144 for 5 years = £720; and wages, £432; total, £1,301. Against this is cost of tractor, £473, plus £449 for running costs, making a total of £922, a net saving of £379.

The final table shows the estimated savings of the Diesel 40 over 15-20 petrol tractor and a 10-horse team for 5 years:—

	£
Sales 7 horses and harness	150
Sale 15-20 tractor	285
Wages 1 man at £144 per annum 5 years	720
Upkeep 7 horses at £8 per head 5 years	280
Upkeep 15-20 tractor £150 per annum 5 years	750
Total sales and savings	£2,185
	£
Cost Diesel, freight, and extras	1,100
24-hoe combine exchanged for two 16's	35
10-furrow plough exchanged for 2 old ones	70
Cost of operating, fuel, oil, and repairs at £110 per annum, 5 years	550
Net savings in 5 years	430
	£2,185

At the end of this period, however, we have still our plant which has another 5 years to run before the depreciation will have run out, so that it can be estimated that by 10 years savings equal to £1,960 will have been made. This means that the Diesel makes savings equal to £196 per annum.

[*Papers Read at Conferences.*]

YORKE PENINSULA, ARTHURTON, 3rd MARCH.

IMPROVING THE PASTURES.

[A. B. Ferguson, Arthurton.]

During the last four or five years wheatgrowing has proved to be far from profitable, and the man on the land has had to look to some other means of profitable production. Stock raising, especially sheep and fat lambs, has proved a great help in trying to balance the budget; also cattle. It would be safe to say that where one cow was milked on the farm 6 years ago there are 5 milked to-day. All this means that the natural carrying capacity of the land has been more than utilised, and as a consequence attention has been directed to increasing the carrying capacity by artificial means, such as top dressing and fodder crops. During recent years prices for wool have not been encouraging. Fat lambs were good, but fat lambs cannot be produced without an abundant supply of early feed. This year the price for both wool and lambs is good, and the season has been most favourable. It is not often that farmers experience such good seasons and prices as has been the case this year. Therefore, the improving of our pastures in average seasonal conditions is a point that should be kept in mind.

Let us consider the question from local conditions. What would be suitable in a country with a 20in. to 25in. rainfall would not be suitable here, where the fall is from 15in. to 17in. The land of this district is devoted almost wholly to cereals, and it is only the land lying out that can be utilised for pastures. The question is: How to utilise that land to the best advantage for grazing stock, whether it be for large cattle or sheep?

The first suggestion would be a heavy dressing of super with the cereals, whether that crop be wheat, oats or barley. Possibly, by force of circumstances, farmers have been practising false economy by using too light a dressing of super, and therefore results from crops are not so good; neither do the stock get the advantage of the feed that would naturally follow a heavy dressing of super. The cereal crop will only use the amount of super it requires; anything over and above that goes to increase the carrying capacity of that land when left out for feed.

The second suggestion would be to sow Cape barley, rye, or oats—preferably Palestine oats; they grow quickly, and would stimulate the land for the next wheat crop. The oats, if sown on stubble, should have at least 60lbs. of super per acre; if on grass land, 70lbs. to 80lbs. Peas are a profitable fodder crop, especially for fattening summer lambs, and would come in when the oat and barley crops were eaten out.

In the June issue of the *Journal of Agriculture* there was a very extensive article written by Mr. R. L. Griffiths (Agricultural Instructor) on increasing the stock-carrying capacity of the mallee farms. He advocated the encouraging of various clovers, of which there is a great number of varieties. Also, he advised the sowing of lucerne, Wimmera Rye grass, King Island Melilot, Evening Primrose, and Early Subterranean clover. Whatever the success or otherwise of these plants, they would be well worth a trial. Just how these plants would affect the land for cereal growing it is difficult to say. Some are already looking on Wimmera Rye grass with suspicion, the idea being that it robs the wheat plant. Attention should first be given to encouraging natural grasses and clovers. It is surprising the number of different clovers that appear after a few liberal dressings of super. The more these can be encouraged the more fertile will the land become. These plants being nitrogenous, it is impossible to estimate the value of them to the land.

Any improvement of pasture must be backed up by the conservation of fodder, because any breakdown in the season may leave us stranded if there is not a good supply of hay, silage, oats or barley stored away to meet any emergency of seasonal conditions.

Every farmer should study his own conditions, and see that every foot of land not under cereal crops is prepared to carry as much stock as possible. Small paddocks close to the house, races, and every small corner should be utilised by sowing with Cape barley and a liberal dressing of super. Stable manure may be all right, but it has a tendency to produce too many useless weeds.

EXPERIENCES ON GROWING PEAS.

[H. J. CADD, Arthurton.]

The pea crop has proved to be most useful and successful, especially if the season is average, or a little better.

The plant revels in light to sandy soil, and if reasonable care be taken in the preparation of the seed bed, the crop will usually return a good margin of profit. Naturally, peas sown on fallow do well. Locally, it is not usual to follow this practice to any extent, generally following barley or wheat with a crop of peas.

Graze the stubble as hard as possible; then during autumn cultivate until a fairly fine surface occurs. When weeds have germinated following the opening rains, again cultivate. This practice leaves the land in a good condition. When the proper time for sowing arrives the combine will effectively deal with any weeds that have germinated since the last cultivation.

June is the most satisfactory month for sowing in this locality. This is rather earlier than farmers sow in recognised pea-growing districts. Excellent results have been obtained from sowings made in May; July, on the other hand, has invariably proved to be too late. The plant appears to have insufficient time to properly mature before warm weather occurs.

Nothing less than 1½bush. to the acre should be sown; if using Brunswick Whites, up to 2bush. can be sown with advantage. Duns can be sown a little lighter. I would not, however, suggest less than 1½bush. to the acre.

Many farmers have given up growing peas because of the prevalence of grubs. This pest in recent years has been particularly destructive in the "Dun" crop for the reason that this variety happens to be in the green pod stage just at the time that the grub is about. The Brunswick variety has the advantage of ripening a couple of weeks earlier, and is, therefore, more or less proof against damage by grubs. Of the two varieties named, the Dun is much the stronger grower, and if the grub menace is escaped, will yield the heavier crop. The Brunswick, however, can always be relied upon to return a fair crop.

The crop has been grown principally for fodder purposes. A good crop—say, 7 to 9 bags—will fatten 8 to 10 sheep to the acre, and is particularly suitable for topping up lambs. Aged ewes also do well on peas. Great care must be exercised when first turning sheep on the crop, otherwise many casualties will occur. Begin with an hour or two, and gradually lengthen the time from day to day, until full time is reached. The sheep should always be removed from the peas if the weather is wet, and not allowed to return until the peas are dry. Never begin grazing the crop until it is thoroughly ripe.

There is little doubt that the sheep-carrying capacity of the average farm could be substantially increased if the sowing of peas was more generally practised, which in turn would mean more profit to the farmer, especially with wool and fat lambs at the good prices now ruling.

Where the rainfall exceeds 15in. peas can, in some measure, take the place of bare fallow, the major difficulty being to properly cope with weeds. Instead of the practice that has become somewhat extensively adopted during recent years of cropping fallow with wheat, burning off the stubble the following autumn, then winter fallow, and sown to wheat the following season, peas could be successfully grown on a portion of the stubble land.

If the practice became general among farmers, it is possible that less wheat would be grown per farm—a very desirable result in a time of over-production and depressed prices. The average production, however, is bound to rise, due to the improved condition of the soil.

Wheat following wheat is more or less a process of mining the soil, whereas rotation of crops is farming. The good farmer aims at the building up of his soils rather than impoverishing them.

The pea crop will add valuable elements to the soil, chief among them being nitrogen. Much of the land is lacking in this essential plant food.

The heavy grazing which follows not only enables many sheep or lambs to be fattened. but the land is put into a much improved condition by the droppings and urine from the sheep. This is a marked contrast to the condition of some of the lighter soils, particularly those that are being subjected to heavy wheat cropping, coupled with continual fallowing; and last, but not least, the heavy loss that is going on yearly by erosion alone.

HORSE-DIPPING.

[S. PONTIFEX, Paskeville.]

In common with many other animals, horses have parasites that infest them and cause considerable distress and discomfort. Gradually farmers have realised the necessity for preventive measures to allay the irritation. It is only 20 or 25 years since "horse itch" was observed in these districts, but it has now become so prevalent as to cause much worry and expense to horseowners. My horses have been dipped annually the last four years, and the fencing repairs saved would pay for installing a private dip.

The need for dipping horses was frequently brought up at Bureau meetings, and eventually a committee was formed to construct and operate a horse dip in conjunction with a sheep dip at Paskeville, on district council property. The first important question was that of finance. About 20 farmers were approached, and subscribed £1 each, on the understanding that their first 8 horses would be dipped free. Later the committee arranged funds at the bank to complete construction costs, and to-day the dip is operating quite successfully.

Cooper's Milk Oil Fluid is used, at a strength of about 1 in 100, and so far it has been found possible to continue operations by charging 2s. 6d. per head, after paying for the fluid and caretaker's fees and general maintenance.

Horses are dipped at the owner's risk, and a notice is posted up to that effect; but in practice there is very little danger. Precautions should be taken against dipping horses when warm; their temperature should be as near normal as possible. Extra care should be observed on the homeward journey to prevent overheating.

At first dipping was done just prior to hay-making, but this has been changed to February of each year, and it has proved the most convenient time. Teams and men are usually on slack time at that period of the year, and there is less bother with the mares.

Owing to the fact that the sheep dip was put down some years ago, it was necessary to construct a separate horse dip, but either sheep or horses could be dipped in a horse dip. The dip is approximately 50ft. long by 3ft. wide, and allows for 3ft. of fluid, with sloping ends. This is long enough to stand 6 horses in at one time, and they can be effectively dipped at the rate of 12 an hour, giving each horse the prescribed time of 20 minutes.

Some people claim the parasites can be eradicated by scrubbing and applying the dip by hand, but this method is laborious and dangerous to the operator, and very wasteful.

Where a community dip is not available, a private dip could be put down cheaply, just big enough for 1 horse to stand in, with only 1 sloping end, and the horse backed into position.

It is advisable to make the dip as small as possible on account of the high cost of a reliable dipping mixture, and once charged all dipping should be completed as speedily as possible owing to evaporation or contamination or rain upsetting the strength of the dip.

The question has been raised, "How often is it necessary to dip?" Some claim that once horses are free there is no need to dip for some years, but contamination takes place either in old yards or sheds, or by other horses. It is preferred to dip as a preventive measure, rather than wait until a drastic cure is necessary.

Farmers should dip their horses as frequently as the need arises, for their appearance is much enhanced, and they carry condition much better on account of being able to feed undisturbed.

THE DESTRUCTION OF THE BLOWFLY PEST.

[L. FORD, Arthurton.]

The only sure method of dealing with the blowfly pest is by destroying the fly, and stop it from breeding, and this can only be attained by trapping the fly. Jetting and crutching are expensive, and are not entirely satisfactory. It is a known fact that the fly blows three or four times during its life, and by trapping this is prevented.

(Mr. Ford exhibited a trap which was made of glass with a wide open neck at the top, and the bottom turned inwards and upwards for a few inches with a wide mouth and lip. The method of its operation was to place it on a kerosene tin which had a circular hole about 6in. in diameter in the top of the tin). When this was done place a generous amount of stale liver (or other meat) in the tin, and pour in about a quart of water to moisten the meat, and thus make a better bait.

Fill the trap with water to within ½in. of the inside lip, and place gently on the prepared tin, the four small legs of the trap itself fitting exactly into the four corners of the tin. Place a small tin or piece of bagging or cloth over the open top of the trap, and everything is ready for catching. It should preferably be placed in a shady place near the sheep yards or watering places, as the flies are usually more prevalent in these places; but good catches can be made anywhere around the sheds or paddocks.

The trap usually only needs baiting once, as once the bottle gets full of flies the dead become the bait, and are by far the most effective of all.

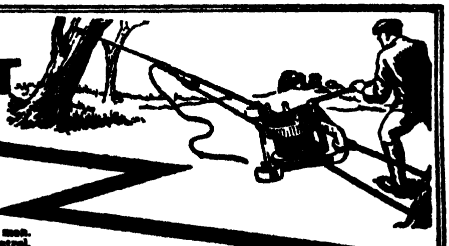
When the trap is catching flies leave it, even if brimming over, until the flies start to blow their own dead inside the bottle; then empty it into a fresh tin with a hole cut in the top, as with the first tin. Rinse out the bottle into the tin, and place again on top, filled with fresh water.

The first tin can now have its contents destroyed, either with boiling water and caustic soda, or by sprinkling lightly the inside of the tin with any arsenical sheep dip powder, and the tin placed on one side. When the bottle is again full the first tin can be rinsed out and used again.

It is fatal to use kerosene anywhere near the trap. Should there be a number of live flies in the bottle when it becomes necessary to empty it, use a small amount of petrol poured through the bagging on the top outlet of the bottle. This soon kills any live flies, and evaporating quickly, does not interfere with the smell of the dead flies.

There is also an alternative method of using the trap. Place it on a piece of board flat on the ground. Fill the trap as usual with water, and add to the water

TEARING THEM OUT



is the regular job of the Monkey Grubber; in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a hand truck, and worked in the same manner as a boat is rowed, it develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

Head Office: MELBOURNE.

in the trap a piece of sodium sulphate, roughly about 1in. square. This will readily dissolve, and turn the water a greenish colour, and the odour given off is attractve to the flies. When the trap becomes full, empty the trap and repeat as usual.

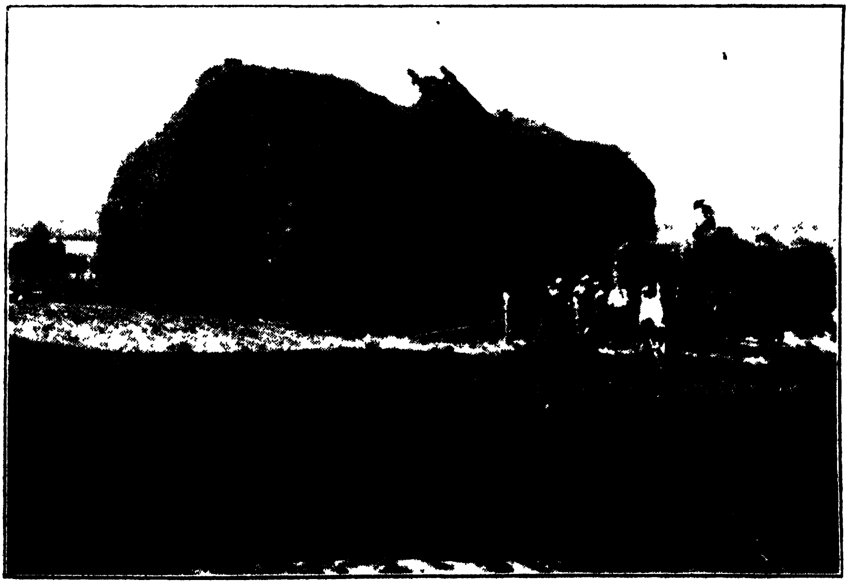
These traps are being used by a number of leading sheep farmers on the Peninsula, and are giving most satisfactory results. They are unanimous in saying that if these traps were used on every farm in a district the fly nuisance would be considerably checked, and eventually made so small that farmers would have to spend much less time on their respective flocks.

At the beginning of summer, when the blowfly pest seems to be at its worst period, I set a couple of traps on a neighbouring farm. Within three days I visited the farm, and found the traps full to the brim with flies of all descriptions, including several bot flies. The majority of the flies were the dangerous green fly, and these were all blowing their own dead, showing how quickly they breed. We emptied these traps and destroyed the flies, and in two days they were full of flies again.

The chief breeding grounds of the flies appears to be the dead carcasses lying about the farms. Many farmers are very neglectful of their duties in this respect. Every dead animal should be either burnt or buried immediately. Follow this practice up by installing some recognised blowfly traps, then the blowfly menace would be considerably reduced, which means added profits to the farmer.

RIVER MURRAY SWAMP AREAS—FIELD DAY.

There was a particularly good attendance of settlers from the irrigation districts in the vicinity of Murray Bridge, when the Annual Field Day of the River Murray Swamp Areas was held on Messrs. H. W. Morphett and Co.'s property at Wood's Point.



Stacking Meadow Hay, Woods' Point Field Day, February 20th.

Mr. H. H. Jericho (Chairman of the Jervois Branch of the Agricultural Bureau) introduced visiting officials and speakers for the day and thanked Messrs. Morphett and Co. for placing their holding at the disposal of the Bureau. The Hon. A. L. McEwin, M.L.C. (Chairman of the Advisory Board of Agriculture), opened the proceedings, and addresses, amplified with a loud speaker, were given by Messrs. W. J. Spafford, H. B. Barlow, and C. F. Anderson, of the Department of Agriculture, Mr. R. Baker of Roseworthy Agricultural College, and Mr. H. Trumble, M.Sc., of the Waite Research Institute. Mr. P. J. Baily, Manager of Wood's Point and a member of the Advisory Board, also gave a short address in which he outlined some of the general practices adopted in the management of the swamps.

River Murray Swamp Settlers' Field Day, Woods' Point, February 20th, 1936

MEDITERRANEAN GRASS.

[*Desirous of ascertaining the origin of Mediterranean Grass, its distribution and use throughout the world, Mr. R. L. Griffiths (Agricultural Instructor) forwarded samples of the plant and seed to the Director of the Royal Botanic Gardens, Kew, England. Below is a statement which Mr. Griffiths received in reply.*]

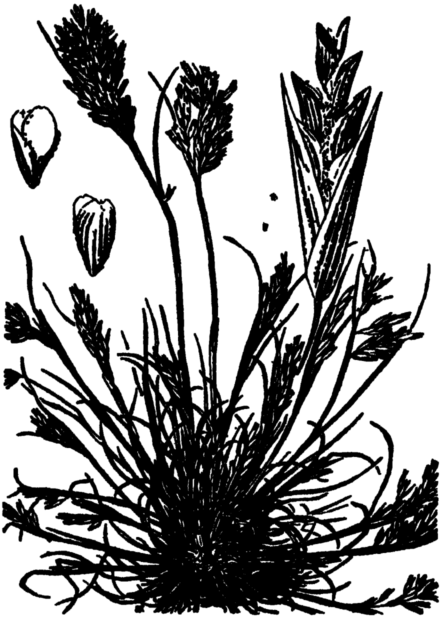
Name.—*Schismus barbatus* (L.) Thell.

Synonyms.—*Schismus calycinus* Duval-Jouve, *S. fasciculatus* Beauv., *S. marginatus* Beauv., *S. brevifolius* Nees, *Festuca barbata* L., *F. calycina* Loefl., *Koeleria calycina* DC.

Distribution.—A native of the Mediterranean region, extending from the Iberian Peninsula and the Canary Islands through the coastal regions of Southern Europe and Northern Africa to north-west India and Central Asia. Also in South Africa, where a variety of forms occur. Introduced into the United States, Argentina, Western Australia, South Australia, Victoria and New South Wales.

Ecology.—In the Mediterranean region it is of frequent occurrence on maritime and river sands, in cultivated fields, field-margins, paths, roadsides, dry grasslands, wall-tops. It occurs from near sea-level up to 1600 m. in the lower parts of mountains.

Economic Uses.—In its native habitat this species is usually regarded as of little value, but as it grows in areas of low rainfall where many of the grasses are tough and unpalatable, it must provide a certain amount of grazing. It seems to be of greater use in the countries where it has been introduced. In the southern part of the State of Arizona (U.S.A.) it has become locally dominant, having spread quite rapidly (in the open ground), along roadsides and dry river beds. It is stated to be an excellent winter forage grass, growing during late winter and spring months, and with irrigation remains green and continues growth throughout the summer season.



Mediterranean Grass (*Schismus barbatus*).
Plant x ½: Spikelet and Florets x 5.
[*From U.S. Dept. of Agric., "Manual and Grasses," by A. S. Hitchcock.*

Habit.—An annual or short-lived perennial from 2-15ins. tall. It produces numerous very slender culms and fine leaf-blades, contracted panicles and an abundance of seed.

ALMOND TREES DYING.

A member of the Greenock Branch of the Agricultural Bureau states that in the 1935 planting season, a number of almond trees were planted where they would receive the drainage from horse stables. The trees originally made good growth, but subsequently all have died. Mr. A. G. Strickland, M.Sc. (Chief Horticultural Instructor), to whom this question was referred, says:—"Fresh drainage from horse stables should not be applied to growing plants, as the material may contain compounds which are toxic to plant growth. For instance, farmyard manure of any sort should be rotted down before application to young trees. From another viewpoint, it is noted that almond trees are most intolerant of 'wet feet'; if the volume of drainage is sufficient, or the location of the trees such that they were subjected to waterlogged soil conditions, this factor alone would be sufficient to account for death."

OFFICIAL SINGLE TEST EGG-LAYING COMPETITION, 1935-36.

CONDUCTED AT PARAFIELD POULTRY STATION.

ONLY FIRST GRADE EGGS RECORDED.

SECTION 1.—WET MASH.

Class No. 1.—White Leghorns.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April, 1935, to 29th February, 1936.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal: 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 31st January, 1936.	No. Eggs Laid Month of February, 1936.	Total Eggs Laid 1st April, 1935, to 29th February, 1936.

No. 5 Test	5,599	560	6,159

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO. LIMITED reported on 2nd March, 1936.

BUTTER.—Since our last report production has shown a seasonal decline each week. This has been more pronounced in the quantity of top grade butter which is now short of local needs, although there is a surplus of lower grades which is being packed each week for London. The London butter market during the last week or two has weakened and prices came back. However, under the equalization plan it has not been necessary to alter local prices, which at present are ruling at:—Choicest creamery fresh butter, in bulk, 1s. 3¾d. per lb. Prints and delivery extra (this price is for local sale only, and under the quota system, the equalized price manufacturers will receive will be 1s. $^{15}/_{16}$d. per lb., on which basis payments to cream suppliers will be calculated); separator lines, from 11½d. to 1s. per lb. for choicest; stores, 7d. to 8½d. per lb. (these prices are subject to equalization levies).

CHEESE.—As with other produce this commodity is now being manufactured in lessened quantities, but the tonnage this season has easily constituted a record. Shipments have gone forward regularly to Britain, but within the next week or two all that is manufactured will be required for the trade within the Commonwealth. Local prices are steady at:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. 1d. to 1s. 1½d. per lb.

EGGS.—The supplies reaching the packing floors have kept up fairly well for this time of the year, but owing to the warm weather the quality of many country lots has been poor. As soon as the cooler weather sets in no doubt an improvement will result and prices advance. In the meantime values are:—Ordinary country eggs, fair average quality, from 5d. per dozen net; long distance rail or shipping eggs, lower; selected new laid clean eggs, full-sized, 9½d. to 10d. per dozen net.

BACON.—A steady trade in bacon was recorded throughout February, and sales of hams and bacon factory small goods were well maintained. Present prices are:—Best quality sides, 9d. to 9½d. per lb.; middles, 9½d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 1s. 0½d. to 1s. 1d.; cooked, 1s. 3d. to 1s. 3½d. per lb.; lard, bulk, 5½d. to 6d., prints, 6½d. to 7d. per lb.

ALMONDS.—Consignments of the new crop are now coming to hand, and where the almonds are nicely dried out ready sales are being effected at quotations:—Softshells and Brandis, 8½d. to 9d.; hardshells, 5d. to 5½d.; kernels, 1s. 9½d. to 1s. 10½d. per lb.

HONEY.—There is no improvement to report in the trade of this commodity, demand still being dull. Heavy stocks are held by wholesalers in the city and quotations have not altered, being:—Prime quality clear extracted, 2d. to 2½d.; lower grades, 1d. to 2d. per lb.

BEESWAX.—Rather heavier supplies have been marketed during recent weeks and trade was quiet at:—1s. 2½d. to 1s. 3½d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms which are in every way the best equipped in the State. The demand for all classes of birds in our markets has been well maintained, and except for slight fluctuations values continue fairly steady. No doubt prices for good quality birds will improve with the nearer approach of Easter. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. 6d. to 4s. 6d.; nice-conditioned cockerels, 2s. 10d. to 3s. 5d.; fair-conditioned cockerels, 2s. to 2s. 8d.; chickens, lower; heavyweight hens, 2s. 2d. to 3s.; medium hens, 1s. 8d. to 2s. 1d.; light hens, 1s. to 1s. 6d.; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. 2d. to 4s.; young Muscovy ducks, 1s. 10d. to 2s. 5d.; ordinary ducks, 1s. to 1s. 9d.; ducklings, lower; geese, 2s. to 3s. 6d.; goslings, lower; turkeys, good to prime condition, 9d. to 1s. 1d. per lb. live weight; turkeys, fair condition, 7d. to 8d. per lb. live weight; turkeys, poor and crooked-breasted, lower; pigeons, 3d. to 3½d. each.

POTATOES.—New season's, 7s. 6d. per cwt.

ONIONS.—New season's, 9s. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of February, 1936, and also the average precipitation for February, and the average annual rainfall.

* No report received during the month of February. R In recess.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from August 1st, 1934, with the following exceptions:—Life Members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

LIFE MEMBERS.

At the February meeting of the Advisory Board of Agriculture the names of Messrs. F. H. Wolf and G. C. Heinjus (Rosedale) and H. A. Eckert (jun.), of Belvidere, were added to the roll of Life Members of the Agricultural Bureau of South Australia.

MACHINERY.

POWER FARMING.

The Booleroo Centre Branch has recently been re-organised after having been in recess. At the September meeting nine members were present and the following paper was presented by Mr. J. Heddle:—Probably no question in connection with cereal growing has aroused more controversy in recent years than power farming. Before embarking on a power farming scheme the farmer must ask himself the following questions—(1) "Am I prepared to pay careful attention to the tractor to ensure successful working, with a minimum of expenditure for upkeep?" The type of farmer who is satisfied to work sore-shouldered, tender-footed, underfed horses, or one who thinks that a wire twitch does as well in a machine as a bolt, will never be a successful power farmer, for while a team of horses will keep on working under neglected conditions, a tractor certainly will not. Thoroughness and cleanliness are absolutely essential. (2) "Is my financial position such as to warrant the outlay?" (3) "Is my land suitable for power farming?"

In districts where the regular growing of hay presents no difficulty and early paddock feed is a regular feature, the change over is not likely to be so successful as in the purely wheat districts. In the first mentioned districts, many farmers consider that the feed consumed by horses could be more profitably used in the production of fat lambs and wool. (4) "Is the type of tractor I am considering purchasing suitable to the type of farm on which it is intended to work? The farmer having answered these questions in the affirmative one can consider the advantages and disadvantages of the change over.

ADVANTAGES.

The ability to carry a greater number of sheep than where horses are kept:—When power farming first came into vogue, many farmers went on to the two-year system—wheat-fallow—but in later years a better rotation, generally speaking, has been practised. Speaking of my own case and observations generally, the number of sheep carried has been practically doubled, and as the money thus earned is the easiest obtained on a farm, this is no small advantage.

Ability to do the work on hand in a shorter time:—The sowing of wheat at the right time leads to an increased yield, but as has been proved many times, no one knows at seeding which crop will be the most profitable, although it is definite that in 9 years out of 10 wheat sown after the opening rain of the season is a more profitable crop than the one sown dry. It is also known that more ground can be fallowed, harrowed, and cultivated while in a moist condition than with a horse team, and as this helps to conserve moisture, it is a real advantage. The same applies in the case that more wheat can be put into the bags in a day with power farming.

The need to employ less labour:—Through the ability to do his paddock work more quickly, the power farmer is able to devote more time to other farm activities such as attention to stock, control of noxious weeds, repairs to and erection of fences, all of which mean a saving.

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SUMMER, 1936.

Eggs for Hatching and Day Old Chickens

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.

DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

BLACK ORPINGTONS.

EGGS.—10s. per Setting of 15 Eggs. Incubator Lots, £2 per 100.

DAY OLD CHICKENS.—17s. 6d. per dozen ; £4 per 100.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.

DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

Free on Rail, Salisbury.

DELIVERY.—CHICKS—January to March.
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2oz., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

"First Aid to the Horse" by F. E. Place, B.V.Sc., M.R.C.V.S. Price 3s., Posted, 3s. 2d.

"Journal of the Department of Agriculture"—Subscription 5s. per annum to addresses in South Australia. elsewhere 10s. per annum. Members of the Agricultural Bureau of S.A., 2s. per annum.

Single Copies, 1s. each.

The extra amount of leisure enjoyed through not having to feed and care for horses when not working:—Horses have to be fed and watered regularly for at least eight months of the year and the careful farmer makes a point of regular inspection for the rest of the period. This spare time can be devoted to relaxation, which helps to make farm life less tiresome.

ARGUMENTS AGAINST POWER FARMING.

That the feed used for horses is grown on the farm and that fuel for tractors has to be purchased:—This is the case, but it must be remembered that the average cut for hay has a definite cash value. For instance, if 30 acres of a crop averaging seven bags with wheat at 3s. a bush. is cut for hay, it represents an outlay of £94 10s. less harvesting expenses. These figures are used merely for the purposes of explanation. On occasions, such as when a crop has been frosted so as to be valueless for wheat, it is a real asset for hay, and on the other hand a short wheat crop makes expensive hay. With horses, the value of the hay is taken out before using, while with a tractor the wheat can be sold, the money banked, and the fuel expenses spread over the whole year.

That the introduction of hay and consequently less hay being cut and more wheat placed on the market has provided the surplus which has been causing low wheat values: —Undoubtedly a certain amount of extra wheat has been placed on the market, but not enough to make any difference. The fact is the world is going through one of the periods when the value of all primary products is at a low ebb. These low periods have always occurred. In 1891-1896, before tractors were thought of, wheat was of less value than it is to-day.

That with horses breeding operations are carried out and the team kept up to strength with young horses:—This actually happens only on an occasional farm. It is a rare thing to find a farmer able to rear sufficient horses for his needs. It is no unusual thing to be shown a foal which has cost its owner from £10 to £15 in stud fees. It is quite the usual thing to be told that the high prices for horses are due to farmers going back to horses, but careful observation reveals that not 1 per cent. of horses sold are purchased for that reason. They are purchased by farmers who neglect to breed enough for their use or who tried and were not successful in doing so.

That the introduction of tractors leads to unemployment for farm labourers:—This is so to a certain extent, but so has every other kind of farm implement; the multi-purpose plough, binders instead of mowers, harvesters instead of strippers and winnowers, combines instead of drills, &c., have contributed, so that the whole fault cannot be laid on the tractor. It is said that the tractors have ruined blacksmiths and saddlers. The only difference to the blacksmith has been the loss of shoeing, a fact which few smiths regret. Saddlers have certainly lost trade, but the keepers of petrol and oil depots have gained, and when one takes into consideration the increased amount of freight on the railways, which needs extra men to handle, mechanics, &c., it is very doubtful if any unemployment is caused.

The tractor has proved of great advantage in certain portions of newly taken up country, particularly for scrub rolling. In opening up new country it saves the cost of stables and water provision—a big item. The use of the tractor is looked on askance by many farmers, but it is really only another step in the mechanisation of farming. Sinister fears were expressed by farmers where super, drills, harvesters, dry pickling and other new and improved methods came into being; in fact, the introduction of mechanical power into any industry at first aroused suspicion right from the time of the introduction of machinery into the Lancashire mills. Mechanical power has been the means of reducing the costs of production in every industry, and with the advent of Diesel engines, which are reaching a high state of efficiency, it seems certain to do as much for the wheatgrower.

After an exhaustive inquiry the Wheat Commission in a statement on the costs between horses and tractors gave them as equal This appears to make power farming more profitable when wool and labour are considered.

A detailed comparison of costs of tractors and horses has not been made in this paper. In nothing is the old saying, "One's man meat is another man's poison" more clearly proved than in power farming. Conditions and costs of both horses and tractors differ so much that comparison needs to be spread over a period of years. In any case, the final result is the true statement of costs. One man's expenses may be £50 less than another, yet the man with the bigger costs may produce more than that amount extra. Two adjoining farms each using horses may have a difference of 25 per cent. to 30 per cent. in their total products value for the year, so with tractors, the success or failure is largely a matter of the individual. After eight years of power farming, I am convinced that to me it has been a profitable investment, and that the golden rule for power farmers is care. (Secretary, J. McCarthy.)

CARE OF FARM MACHINERY.

At a meeting of the Baroota Branch held on 9th December, Mr. W. A. McDougall read a paper on the above subject. In building a shed for the protection of farm implements he preferred a double lean-to type with the opening towards the south. Sliding doors were satisfactory while new, but after a time they might give a good deal of trouble. Instead of fitting doors, the shed could be built several yards wider than the machinery that it was to contain. No more iron would be used than would be needed for doors, and it meant less expense and trouble. Woodwork on farm machinery should be painted regularly. A good cheap paint could be made up by mixing red lead and boiled oil with a small quantity of turpentine and carriage varnish. A colour to match the red paint could be obtained by mixing yellow ochre, boiled oil, a small amount of white lead, turpentine, and carriage varnish The paint might appear dull, but it could be brightened and altered to different shades by adding colour concentrates, a small tin of which could be bought for a few shillings. It was a good practice to soak all wooden wheels every year or so in hot boiled oil. Care should be taken not to heat the oil too much or it might be spoiled. The best method was to make a special pan of galvanized iron. The pan was placed beneath the jacked-up wheel and the heated oil poured into it. A few hot coals placed beneath the pan would keep the oil hot. The wheel was then slowly turned in the hot bath of oil. A brush shold be used to spread the oil on to the nave and spokes. If done regularly the oiling would add years to the life of the wheels and save much expense in repairs.

On sandy properties tillage implement axles would last much longer if sand guards were fitted. Pieces of old binder canvas were suitable for the purpose. It was advisable to leave an opening in the bottom of the sand guard instead of wrapping the canvas right around the inside of the wheel hub.

WORN BEARINGS.

The most economical treatment for worn bearings was by the use of Magnolia metal or white-metal, which could be used by the average farmer. To repair a worn bearing with Magnolia metal several small holes should be bored through the casting on the side of the worn bearing, in order to hold the metal in its place. The next operation was to take a piece of shaft of the same size as the original, paint it with stove polish, warm both shaft and bearing, and place the shaft inside the bearing. While this was being done some metal should be melted in a ladle. A piece of dough should be made from flour and water and placed around the shaft at each end of the bearing, also over the holes in the casting, leaving one open, through which to pour the metal. It was sometimes advisable to tie a piece of cloth over the dough in order to prevent the hot metal from leaking through. After the metal was poured, the shaft should be removed from the bearing as soon as the metal was set and before it cooled. Worn shafts could be repaired in the same manner, except that the holes should be bored in the shaft instead of in the bearing, and the stove polish painted on the bearing instead of on the shaft. Where Sundercut disc bearing were not too much worn they could be repaired by running metal into the top part of the back half of the bearing. Holes should be bored in the bearing in order to keep the metal in place. Where bearings were too hard to bore, it was necessary to tin them before pouring the metal. Before tinning, the inside of the bearing had to be thoroughly cleaned and a thin layer of solder placed on the worn part with a soldering iron. When ready for pouring the metal, the bearing was heated from outside with a blow lamp until the solder commenced to melt, when the metal was poured in. (Secretary, E. W. Hulster.)

WHAT THE FARMER SHOULD PRODUCE FOR HIS TABLE.

Paper read by Mr. A. B. Brook at a meeting of the Hartley Branch, held on 4th December:—

In this district, most farms are comparatively small, and therefore mixed farming is carried on, thus enabling the farmer to produce on his own farm a large percentage of foodstuffs for his table. Most people like porridge for breakfast, and a very healthful and palatable porridge can be made out of wheat. Most farmers have a crusher or grinder for crushing cereals for stock food, and this machine is quite suitable for crushing wheat for home use. When the wheat is crushed a sieve is required with which to sift the bran from the rest of the crushed wheat, and the porridge meal is then ready for cooking.

The next course at breakfast is bacon and eggs. It is quite possible for the farmer to produce both of these articles for his table. It does not require many head of poultry of a good laying strain to produce enough eggs to supply the household all the year round. During laying season, eggs can be pickled for use during the moulting season. Most farmers keep a few pigs for fattening purposes and occasionally one of these could be slaughtered for home use. Winter is the best time for this, as the meat keeps better than in summer, but properly cured bacon will keep for a good length of time. If one carcass is too much for one family, make arrangements with a neighbour to share the meat and the expenses. However, the best plan is to kill a fairly small pig—about 120lbs. dressed weight—and this is not too much for the average family on a farm, including the working hands.

Other meats obtainable on the farm are beef, mutton, and poultry. Beef can only be killed in winter, as there is too much of it to keep well in the hot weather, but mutton can be killed at practically any time, as there is not very much of it—between 60lbs. and 80lbs. generally. When slaughtering beef, the best meat is obtained from a steer about 18 months or 2 years old, which has been fattened and is well grown.

A farmer can supply the home with vegetables and fruit from his land. Fence off a piece of land fairly close to the homestead so that the cook can obtain fresh fruit and vegetables whenever desired. It is not a large garden that is required for home use, but a large variety. Plant two or three almond trees of a good type and two or three apples of varieties which ripen at different times, providing cooking and drying varieties as well as eating; also other varieties of fruit trees and vines. The vegetable garden will prove more profitable than having the greengrocer call at the door, because vegetables do not take up very much of the farmer's time, and the plot can be dressed with stable manure, which is always obtainable on a farm. With the aid of water in summer, vegetables can be grown all the year round and thus ensure a supply of fresh vegetables for the farmer's table. In winter the ground should be well manured and planted with a patch of about 3 or 4 dozen cauliflower and cabbage plants, and small beds each of turnips, beetroot, &c. Do not plant so as to have them all ripening and ready for use at once. By the time the spring crops are nearly finished, prepare the ground for planting tomatoes, cucumbers, and beans. Do not plant too many of these, as they require plenty of water. Potatoes, melons, &c., can be grown in most parts of this district with fairly good results. If farmers produced as much as they possibly could for household consumption, they would be able to live more cheaply. (Secretary, W. J. Brook.)

Annual Field Day of the Blackwood Agricultural Bureau at the Blackwood Experimental Orchard, 7th February, 1936.

TRACTOR *V.* HORSES.

At a meeting of the Nantawarra Branch, on 6th February, Mr. Arthur Bryant read the following paper:—

The fact that the farmer grows his own hay and thereby produces his own fuel for power is by no means a positive proof that he is effecting a saving against buying fuel from overseas for his tractor. Farmers once sowed crops with their own hands and gathered the crops with the help of their wives and families and beat the grain out with a flail.

The material for the post and rail fence was cut by their own hand out of their own scrub. The home was built by his own hands from "wattle and dab," all of which material came off the farm.

Progress saw the imported drill and superphosphate supersede hand sowing; the imported mower, binder, reaper, winnower, harvester, &c., supersede the whole family reaping with a sickle and beating the grain out with a flail. The imported wire and iron fence replaced the post and rail fence. With these changes farmers experienced prosperity and living conditions that our forefathers could never dream of. The hundreds of thousands of tractors now on the farms of the world and the liquid fuel for same is only a continuation of progress. Competition of wheatgrowers throughout the world will force farmers to adopt tractors, because they cheapen the cost of production of wheat.

Opponents to tractors often argue that growing hay for feed (which is only fuel for power) on the farm is to retain and preserve a market. On careful investigation we find that the motor car has practically closed out the buying public, for they do not keep horses excepting in rare instances, and in the years of plenty the price of hay is far below the cost of production.

High prices for hay are not due to the spirited bidding from the public, but are due entirely to shortage of hay on your own farm and other farmers in the same plight bidding against you for the small surplus of hay your neighbour is holding on to. Your fortunate neighbour is extracting from you the highest price he thinks he can get. A team of horses entails more labour, anxiety, and expense than anything else on the farm.

The simplest and most correct way to ascertain the cost of producing a ton of hay is to assume you will cut all your crop for hay. Before one can intelligently compare tractors *versus* horses, the price of producing hay on your farm must be established, as there is a cost attached to producing hay, and to try and ignore this cost is like trying to ignore the fact that the sun rises in the east and sets in the west.

Below is the cost of farming a 600-acre farm in this district, and the average yield per acre is 1¼ tons of hay, which would be the average over a period of good years and lean years. The cost of hay grown as fuel for power is not governed by the fluctuating price list, but is in accordance with the cost of farming a number of acres.

COST OF FARMING 600 ACRES.

	£	s.	d.
Interest on 600 acres at £5 an acre—£3,000 at 5 per cent.	150	0	0
12 horses each consuming 6 tons hay at £2 ton	150	0	0
15 tons of super	78	15	0
375bush. seed at 3s. 4d.	62	10	0
Depreciation of farming plant	20	0	0
Interest at 2½ per cent. on £1,000 plant	25	0	0
15 bales twine at £2	30	0	0
Sundry expenses, repairs, plant, &c.	20	0	0
Rates and taxes, telephone, insurance, &c.	40	0	0
Hired man at harvest time (including board and lodging)	**25**	**0**	**0**
Living expenses based on arbitration awards as cost of living for average family	**166**	**8**	**0**
	£767	**13**	**0**

300 acres crop yielding 25cwts. to the acre = 375 tons at £2 per ton, £750.

It will be seen on the above figuring, which is very conservative, that hay cannot be grown for less than £2 per ton as an average, and then **it is necessary to sell it out of the stack. Also note that it is necessary to have feed paddocks to keep the hay for fodder down to 6 tons per horse.**

The amount for living allowance, £166 8s., is largely offset by eggs, butter pigs, meat, sheep, &c., produced on a well-managed farm, but at the same time it does not lessen the cost of hay growing. It is a profit derived from **sidelines. Note that no interest is allowed the owner for money invested in the land. Careful management will have to be exercised to keep expenditure within the above estimated figures. No holidays, sickness, accidents, or schooling,** motor cars, radios, &c., **are provided for in the above estimated expenditure.**

Above figures are ample proof that it costs over £2 per ton to grow hay and £120 to feed 10 horses for 1 year for power.

The following costs are based on figures supplied by several tractor owners, and for working the land for 12 months from January to 31st December as follows:—

	£	s.	d.
Cultivating 300 acres at 7d.	8	15	0
Combining 300 acres at 7d.	8	15	0
Harrowing 300 acres at 2d.	2	10	0
Fallowing (ploughing) 300 acres at 11d.	13	15	0
Cultivating 300 acres at 7d.	8	15	0
Cultivating 300 acres at 7d.	8	15	0
Harrowing 300 acres at 2d.	2	10	0
Harvesting 300 acres at 7d.	8	15	0
Total	**£62**	10	0

Working 300 acres 8 times each year with a tractor as follows:—Ploughing at 11d., cultivating three times at 7d., harrowing twice at 2d., combining at 7d., harvesting at 7d.:—

	£	s.	d.
Kerosene for working 2,400 acres	62	10	0
Depreciation	37	10	0
Maintenance	10	0	0
Interest on tractor, £215 at 7 per cent.	14	15	0
	£124	15	0

Horspower—

	£	s.	d.
12 horses to maintain a 10-horse team, each horse eating 5 tons of hay per year valued at £2	120	0	0
Depreciation based on fact that average life of horse working is 13 years	25	0	0
Maintenance, allowing for deaths, harness, shoeing, veterinary, fences, troughs, &c.	10	0	0
Seed and super for early feed	30	0	0
Interest on 12 horses valued at £25 at 7 per cent.	21	10	0
Interest on 60 tons of hay valued at £3 at 7 per cent.	15	15	0
	£221	15	0

	£	s.	d.
Farming with horsepower	221	15	0
Farming with tractor	124	15	0
Balance in favour of tractor	£97	0	0

Other savings made through tractor farming are:—(*a*) 120 sheep at 10s. each per year, £60; (*b*) extra time and labour for secondary industries. In other words a tractor will provide the power to work the farm for 8s. 4d. per acre, whereas horses cost 14s. 9d. per acre, the tractor showing a saving of 77 per cent. over horses.

All the above figuring is based on good years and when times are normal. At the present time hay is bringing an extraordinary high price, not because an improved market has been found, on the contrary, hay is high in value because unfortunate fellow farmers through drought conditions cannot grow enough fodder to feed farm stock. Unless you can grow hay on your farm for 17s. 6d. per ton tractor fuel is considerably cheaper. Opponents to tractors cannot grow hay cheaper than £2 per ton, and it is quite plain that they do not know what it is costing them to feed horses.

Science and advanced engineering have produced for the farmer a piece of mechanism that will compete with horses and reduce his farming costs. It is a continuation of the progress from the scythe and sickle.

DISCUSSION.

Mr. W. Starkey did not favour the tractor on account of having to import all fuel from U.S.A. Tractors were dangerous in summer time on account of fire. Mr. A. Herbert said that the costs of horses quoted were not exact enough. Advised the rearing of foals, but agreed that tractor may be pleasanter to work. Mr. G. Henderson said that tractors owned by settlers in Western Australia were discarded when the country was at all settled. Mr. W. Hamdorf said that tractor and horses were not a good combination, as there was too great an outlay of capital for the period of work every year. Mr. L. Belling thought horses were the better proposition of the two, as a tractor owner would have to be a good mechanic. Mr. V. Hamdorf said that the depreciation and the repair bill allowed for a tractor was not nearly large enough as gained by his experience of tractor farming. Hay could be grown for 15s. a ton. Mr. S. V. Herbert said that accidents could happen to both units of power, but he favoured suction gas or crude oil in preference to kerosene tractors. (Mervin P. Hamdorf, Honorary Secretary.)

HAY MAKING.

The following paper was read by Mr. A. F. Roennfeldt at a meeting of the Greenock Branch on 16th December:—

As hay is the main fodder for all farm animals it is essential that all wheats sown for hay should be of good feeding quality. Hay grown on hard red soils is far more nourishing than that sown on black or Biscay soils, on which it grows rank and bulky. This, however, is generally cut for hay, as the return per acre is more than if left standing for stripping.

When cutting hay the grain of wheat in the head should be fairly well developed. If left standing too long, the straw of the hay becomes too white, and the mice do more damage in the stack.

Stooking should be done as soon as possible after hay cutting, as the hay keeps its colour, weight, and shape better than if left lying about for some days. If a little care is taken with stooking there should be very few stooks and twisted sheaves blown around the paddock. A good method of stooking is to stand four sheaves in a row, two on each side, then one layer right around with knots outwards, with the finishing sheaf on the western side.

The most important part of hay making is the stacking, as this is to preserve the hay from the year's rain. A thick layer of straw for the foundation of the stack should be used in order to keep the damp from the ground out of the hay. The hay stack should not be built too wide. A wide stack often has a shallow roof, which has a tendency to let water enter the hay. Keeping the centre of the stack about 2ft. 6in. higher than the outside sheaves of the layer is the most important part of stacking, in order to keep unsightly props and posts from the ends of haystacks.

Thatching the stack should be done immediately after the stack is finished, using good long straw carefully straightened, and put on in a thick layer. Wires across the stack should be 2ft. 6in. apart and anchored down with heavy weights or stones. It is always a good plan to have a little extra hay over at the end of the year, as it reflects bad management on the part of the farmer if he has to buy hay.

Mr. N. Fotheringham, Manager of the Orchard, addressing the visitors on the "Furrow Irrigation Experiments" at the Berri Experimental Orchard on the occasion of the Annual Field Day of the Berri Agricultural Bureau.

TOP DRESSING OF PASTURES.

The above was the subject of a discussion at a meeting of the Tantanoola Branch held on 1st February. Members agreed that a heavy application of super was advisable in the beginning. Mr. Altschwager strongly recommended sowing pastures with suitable grasses, which he claimed was much more profitable than relying upon the native grasses. He believed that rye grass and strawberry clover made the best pasture, and stressed the necessity of a heavy initial dressing of superphosphate. Mr. L. Anness strongly favoured a liberal application of super during the first year of operations. That landholders in Victoria were much more successful with pastures than those in South Australia was, in his opinion, attributable to the more liberal use of super in Victoria. He recommended using a bag of super per acre in the beginning. Mr. Anness strongly advised pasture harrowing on pastures where dairy cows were grazing. The breaking up and more equal distribution of manure over the surface was in itself a form of top-dressing. Cows should be kept off the land for a few days after harrowing. (Secretary, L. J. C. Osborne.)

BREAKING UP ROUGH LAND.

In the course of a paper read at a meeting of the Allandale East Branch on 7th February, Mr. F. W. Thompson dealt with his experiences in breaking up rough ground. He stated that in its original state their land was as rough as any in the district. After grubbing thick wattles and bushes they commenced to plough the land, which was very stony and gravelly, using a single-furrow plough and two horses. A stump-jump plough was used next year and proved much easier for the man although harder on the horses. It was found that using four horses in a two-furrow stump-jump plough was most satisfactory, giving sufficient power to plough fairly deeply, thus removing as many stones as possible during the first year. Two men followed the plough with pick and hammer to remove what stone the plough had missed. The first crop was generally poor but the second crop was much better. Although the cost of the first breaking-up was high, they were well repaid during later years by good cuts of meadow hay. The best time to plough was when the land was wet, because it was much easier to remove the stone from wet land. It was usually a problem to dispose of the ploughed-up stone, there being no sale for flint in the district. They had built the stone into walls for fencing. Although it took a great deal of work, when such a fence was built it was everlasting, besides being a good shelter for stock, an excellent firebreak, and looking better than heaps of loose stones scattered over the property. The small stones which came to the surface in later ploughings were used for making roads and cattle tracks through boggy places and around yards, sheds, &c. Although the breaking-up of rough country entailed much hard labour and expense, it was the best means of improving the stock carrying capacity. During the discussion Mr. Thomson stated that the most suitable method of levelling the land was by several cross-harrowings. This method was better than by rolling, &c. Replying to a member who asked how top-dressing had improved the unploughed land compared with that which was ploughed, Mr. Thompson said that although the uncultivated land had been improved, the cultivated land grew a better class of pasture and made better growth. (Secretary, R. T. Laslett.)

Mount Compass Agricultural Bureau Field Day on Mr. M. Jacobs' property, 6th February, 1936.

HARVEST REPORTS.

At a meeting of the Wasleys Branch on February 6th, Mr. C. Carmichael reported that the season was marked by scanty rains. Although the monthly falls were fairly evenly distributed, only during one month was more than 2in. received. The harvest opened unusually early, and by mid-October hay cutting was general. Thirty acres of Sword wheat cut for hay were estimated to yield 2 tons, a further 50 acres were reaped, yielding 30bush., but the grain was very light. A second paddock of 222 acres was sown with 60 acres of oats, 10 acres Ghurka, 30 acres Golden Return, 100 acres Ford, and the balance Nabawa. The oats yielded 2 tons per acre. The Ghurka did not do well, and the Golden Return was shrivelled on the red patches; the remainder of the crop grew well, and returned 8 bags. All the wheat was sown at the rate of 75lbs. of seed and 90lbs. super per acre. A crop of malt barley was badly affected by strong winds after reaping was commenced, and returned 6½ bags per acre. Thirty acres of Cape barley yielded 30bush. per acre, and was unstained. Mr. A. Helps reported that of the 3 varieties sown, namely, Ranee, Sword, and Ghurka, Ranee yielded 23bush per acre, Sword and Ghurka each 19bush. A return of 4bush. more was obtained from fallow land left out to grass over that from land following a cereal crop. Sword sown with a mixtue of 50-50 super and carbonate of lime (1cwt.) sown on heavy land yielded 3bush. more than that sown with 1cwt. of superphosphate. Malting barley yielded

21bush. No difference was obtained where super and ammonia were applied. Mr. E. W. Day stated that Sword had proved superior throughout the district, being outstanding in the Central Crop Competition. It was subject to smut, and therefore should always be pickled. Several crops of Sword entered in the Competition had received setbacks due to smut. Dundee was a good variety for the district, but the recent baking tests had proved that it was not such a good flour wheat as was reported early in the season. Felix had yielded well on account of the absence of rust during the season. Mr. T. W. Day reported that a frost late in the season had greatly reduced the yield, his crop averaging 24bush. Sword A yielded 30bush. and did not shake in the boisterous winds as did ordinary Sword.

Dudley Branch.—At a meeting held on February 4th Mr. G. Mayfield reported that experiments with varying quantities of seed showed that 65lbs. seed and 95lbs. super yielded about 25bush., a seeding of 80lbs. seed and 95lbs. of super giving a yield of approximately 31bush. Mr. L. Longbottom reported good results from Dundee wheat, which yielded 10 bags per acre, stood up well, and did not shake. It reaped well, and gave grain of good weight. Ranee 4H, however, yielded 2bush. or 3bush. better. Turvey did not yield well. Mr. A. G. Telfer reported no appreciable difference in yield between Ranee, Ranee 4H, Ghurka, and Dan. When fed off, sheep showed a preference for Ghurka, and fed it closer. Stubble crops, peas, oats, and barley were disappointing, largely owing to dry spring conditions. A patch of Early (Dwalganup) Subterranean clover had made good growth.

Alma Branch.—Eight members attended a meeting on 4th February. Mr. W. H. Brown reported that Sword returned 12 bags, Waratah 10 bags, and Marathon 25bush. Nabawa was disappointing, yielding 18bush. Hay averaged 30cwts., and barley 8 bags. Mr. R. McKenzie reported a return of 30bush. from Sword; Nabawa yielded 7 bags, with a coarse straw and tight heads; Wandilla, 7 bags; and Croston, sown early, 21bush. Smut was the only disease. A test plot sown at the rate of 1cwt. per acre of super and ammonia yielded 1 bag per acre more than a plot which received 90lbs. of super only. Mr. M. McKenzie stated that Sword had returned 9 bags in one field and 10 to 11 bags in another; Waratah, a good crop, yielded 9 bags; Nabawa broke off badly, yielding 7 bags; Marathon also broke off, yielding 6 to 7 bags. Smut was the only disease. Mr. H. B. Freebairn had received the best return from Ranee 4H, which gave 11 bags. Ford returned 30bush., and Sword, which had been fed off, 30bush. The Sword which was not fed off yielded 8 to 9 bags; Waratah, 6 to 7 bags; Caird, a wheat which had given good results, yielded 9 to 10 bags. Mr. A. E. Day reported Dundee, 11 bags; Waratah, 10 bags; Ranee, 8½ bags; Nabawa, 8 bags; and Sword, 9 bags. Dunn's and White peas were raked and stacked, and were being fed to sheep with good results. Mr. A. R. Smyth reported that Dundee and Ranee returned 14 bags, weighed well, and gave a good sample. Ford (13 bags) and Sword (11½ bags) were disappointing; Nabawa went down, yielding 10 bags, and Marathon, which broke off, gave 39bush. The disease "failure to fill" affected Dundee and Ranee, as well as smut and flag smut on limestone soil. Mr. E. H. Drescher reported Sword, 8 bags, and Nabawa, which broke off, 7 bags. Members reported damage to barley by heavy winds which adversely affected the yield.

Boor's Plains.—At a meeting held on 6th February 28 members and visitors were present. Harvest results were discussed, the average return for the district being 20bush.

Jamestown.—Meeting held 17th February. The average yields per acre of wheats were reported as:—Carrabin, 24bush.; Dundee, 29bush.; Sultan, 27bush.; Nabawa, 27bush.; Ranee 4H., 31bush.; Gallipoli, 27bush.; Sepoy, 30bush.; Currawa, 25bush.; Sword, 25bush.; Ranee, 28bush.; and Ghurka, 23bush. Oats—Early Burt, 18bush. Mr. A. J. Symonds reported that 3 plots of oats sown as Departmental Experiments resulted as follows:—1cwt. super per acre, 15bush.; 2cwts super and 1cwt. ammonia at rate of 2cwts. per acre, 18bush.; 1cwt. super and 1cwt. ammonia at rate of 2cwts. per acre, 25bush. Members had noticed that the straw of Currawa, Sepoy, and tough Gallipoli was eagerly sought out by stock, while that of Ranee and Nabawa was practically ignored. The increased feeding value of the straw helped to compensate for decreased yields in the first-named varieties.

Gladstone.—A meeting was held on 12th February, each member present giving a report of his harvest result. Mr. Fisher reported having experimented with Bogan, a New South Wales wheat. Mr. Prior advocated the use of a culti-packer, which had prevented his wheat from thinning out. Mr. E. L. Orchard (District Agricultural Instructor) commented upon the crops of the district.

Redhill.—Six members were present at a meeting held on 11th February to discuss harvest results. Mr. Bentley reported his poorest crop since 1914, due to lack of rain and dry, windy periods. His rainfall was about 12in. for the year, although only 5 miles north of Redhill the rainfall was nearly 17in. Waratah gave the best return, yielding about 7bush. Minister, S.H.J., Sword, and Dundee averaged 5bush. Barley and oats were a failure. Mr. F. A. Wheaton had sown one paddock with 1½cwt. of super, which returned nearly 2 bags per acre more than did a paddock sown with 100lbs. of super. Mr. G. A. Button reported that portion of a paddock which had been sown with oats previously showed a better yield than the other portion. Nabawa yielded best, but Ranee gave the heaviest grain.

Appila-Yarrowie.—At a meeting held on 7th February members reported that returns were approximately average for the district. Crops were affected by lack of rain, and frosts did some damage. Mr. E. L. Orchard addressed the meeting, and discussed the harvest results. Mr. Symonds, a visitor from Yankalilla, gave a brief outline of the country in the Yankalilla district.

Wilmington.—At a meeting on 12th February members reported yields varying according to the rainfall. Grasshoppers had done considerable damage in parts. Some good crops were obtained near the hills. Mr. E. H. Hampel reported yields from 18 to 30bush., Sword yielding 30bush., Dundee 27bush., and Gallipoli and Ranee 24bush. Practically all crops were sown in dry conditions, with super at the rate of 90lbs. per acre. Mr. J. J. Modystach received returns up to 25bush., and Mr. F. G. Schulz up to 24bush. Dundee gave promising results under dry conditions. Mr. E. L. Orchard spoke on the subject of wheat varieties.

Murraytown.—Members reported on harvest results at a meeting held on 1st February. Mr. F. C. Borgas reported that wheat sown at the rate of 60lbs. with 75lbs. of super had returned:—Ranee, 20 to 27bush.; Dundee, 9 bags. Ghurka was sown early, and suffered from lack of rain in early October. Oats had returned 10 bags. Mr. N. Scholz sowed 60lbs. wheat and 56lbs. super. Teagle yielded 10 bags of a good sample, Ranee 9 to 10 bags, Sword 7 bags, Free Gallipoli 9 bags, Ghurka 9½ bags. Mr. F. J. Tregenza stated that the distribution of the rainfall had been good for the growing of wheat on fallow, his fallow crops returning 10 bags, and 5 bags from stubble land. Guyra oats gave a good yield. Mr. W. Ryan reported that Sword had shaken badly, but yielded 10 bags. Mr. E. B. Pitman sowed 60lbs. to 65lbs. of wheat with 90lbs. of super. Dundee gave 10½ bags of pinched grain It was a good wheat to thresh, and held in the head well. Marshall's No. 3 returned 8 bags, Ghurka 8½, Rance 9 and 11 bags. All grain except Dundee was of excellent sample. Rance had shaken out approximately 1bush. per acre.

Laura Bay.—Meeting held 11th February. Mr. W. Edson reported Ranee with a yield of 16bush. per acre and Canberra affected by rust. Mr. J. W. Blumson reported considerable damage by wind and rust. Waratah returned 7bush. Red rust was prevalent throughout the district, and the dry mid-winter conditions were responsible for many disappointing yields. A paper, "Scrub Clearing" was read by Mr. M. Lowe.

Coonalpyn.—The subject of the meeting on 5th February was reports by members on their harvest results. Results from wheat were generally on the poor side, although barley and oats gave a better return. One or two crops from a limited area returned approximately 5 bags per acre, but the majority were not over 5busn. Mr. Venning reported that from a self-sown crop of 20 acres of oats grazed until October he had reaped 100 bags. Mr. J. Haydon had sown wheat and barley for 2 years, and during that period the barley returns had been treble that from the wheat.

WOMEN'S BRANCHES.

FIRST AID IN THE HOME.

[*An address given by Dr. S. C. Downing at the February meeting of the Gladstone Branch.*]

In this subject of first aid it is my intention to deal with a few of the more common accidents and mishaps occurring in everyday life, and to suggest suitable methods and simple means of treatment, and in the case of more serious emergencies to outline briefly the best procedure to adopt until such time as more advanced treatment is possible.

In every case the methods or means suggested will be those requiring no special technique, and should be at all times available in the average home.

Simple Wounds and Abrasions.

Regarding these little need be said as the primary factor to be observed is cleanliness. They should be thoroughly washed, preferably using boiled water, and if very dirty there is no objection to the use of soap, a superfatted soap such as Castille or Palmolive being the best. The soap should always be washed off. Remove any foreign particles such as glass, metal, or gravel. Hydrogen peroxide is a good cleansing agent, and when thoroughly clean touch lightly with weak iodine, and apply a clean dressing.

Do not be alarmed at a little bleeding, as this has a cleansing effect. If profuse it can often be controlled by the application of firm pressure over the site of the injury. If, however, the bleeding cannot be controlled by this means and becomes alarming, a tourniquet may have to be applied until such time as the bleeding point can be secured. An ordinary twisted handkerchief will make a satisfactory tourniquet, and is applied tightly above the bleeding point. It can easily be remembered that in the case of wounds of the hand or forearm it must be applied above the elbow, and in wounds of the foot or lower leg it must be applied above the knee. It should not be left in position longer than half an hour before being released, and if necessary re-applied.

Insect Bites and Stings.

These are of extremely common occurrence, but it is fortunate that in this part of the world, apart from the local reaction, they rarely cause serious complications. The first step is to remove the sting if present, and this can usually be done by gentle wiping. For bee stings it is usually sufficient to apply a compress of equal parts of ammonia and water. For wasp stings, equal parts of vinegar and water. Spider and scorpion bites may be treated with a strong solution of washing soda, and in all cases, if very painful, hot fomentations of carbonate of soda, a tablespoon to the pint, usually gives relief. The old-fashioned blue-bag, or the juice of an onion is not to be despised, and is often efficacious.

Foreign Substances in Eye, Ear, Nose, and Throat.

(*a*) *Eye.*—In all cases, particularly in children, avoid rubbing the eye. If the foreign body is embedded in the substance of the eye, make no attempt to remove it. Instil a few drops of olive or castor oil, and bandage the eye. If, however, it is loose and can be easily seen it may be wiped off with a fine brush, the twisted corner of a clean handkerchief, or a wisp of moist cotton wool.

If situated under the upper lid it may sometimes be wiped out by pulling forward the upper lid and pushing the lower lid up underneath it, and repeating this procedure several times.

(*b*) *Ear.*—If the foreign body is an insect it may sometimes be washed out by filling the ear with warm oil, but on no account should the ear be probed or any force used, as it is very easy to damage the sensitive structure of the ear-drum.

(*c*) *Nose.*—If vigorous blowing with the free nostril blocked is unsuccessful, encourage sneezing by inhaling some irritant substance such as pepper or mustard.

(*d*) *Throat.*—The source of trouble most common is a morsel of meat, a piece of bone, or even false teeth. Vigorous thumping between the shoulderblades sometimes has the desired effect. If not, pass two fingers back over the tongue and endeavour to pull up the obstruction.

Simple Sprains.

In a sprained joint it is important that one should always remember the possibility of an underlying fracture, and if any doubt exists further advice should be sought. If seen at the time of injury apply cold compresses and bandage firmly over a layer of cotton wool.

If the swelling becomes excessive and the pain acute, alternate hot and cold fomentations, followed by firm bandaging as before, should give relief. Passive movement and massage should be adopted after 48 hours. If the ligaments are badly sprained or torn some special form of strapping will probably be required.

Fractures.

In the case of fractures, unless one possesses some advanced knowledge of First Aid work I advise gentle handling and as little handling of the affected part as possible, as it is exceedingly easy in some cases to convert what might be a simple fracture into one of a far more complicated nature.

About all that can be done in the home is to immobilise the part in the most comfortable position. It is well to remember that an anaesthetic may have to be given, and to refrain from giving food.

Burns and Scalds.

These injuries are relatively common, and it must be emphasised that in burning or scalding accidents, where the area involved is extensive, no matter how superficial, the condition should be regarded as a serious one. All burning patients suffer from shock, and the first essential is that they be kept warm, and the burnt part not exposed to the air more than possible. Stimulants should be given —strong coffee being quite suitable and usually readily obtainable. Clothing must be removed very carefully, if necessary cut away. Where the clothing is adherent it should be carefully soaked off with a warm solution of carb. soda. The old, time-honoured custom of applying some oily or greasy substance such as olive or carron oil dies very hard, but it is not to be recommended, as it tends to interfere with the more modern methods of after treatment, and also favours the formation of septic conditions. Simple and small burns usually respond quite well to carb. soda compresses, followed later by some simple dusting powder. More extensive and severe burns may also be treated with carb. soda compresses until further treatment is available.

Fainting, Fits, Convulsions.

With the treatment of a simple fainting fit not due to injury most people are probably conversant. The clothing should be loosened, the head placed in a low position, and as much fresh air obtained as possible. If able to swallow, stimulants such as hot strong coffee or brandy may be given.

Fit.—These may be of various natures. All that can be done in the home is to see that the patients do not injure themselves. Remove all breakable articles, and prevent the tongue being bitten by separating the teeth with some blunt instrument.

The hysterical fit is of a different nature, and the difficulty in these cases is in arriving at the correct diagnosis. Hysteria is more commonly found in young girls. The patient rarely becomes fully unconscious, and never under any circumstances hurts or injures herself. The commonest manifestations are uncontrollable screaming, and often alternate fits of laughter and crying, combined with some form of convulsive movement. The treatment in these cases should be entirely unsympathetic. Sometimes complete isolation will suffice, but often more extreme measures have to be resorted to, such as a douche of cold water to the face or [illegible] shaking.

Convulsions.—These commonly occur in infants, and the only home measure available is the hot bath. Mustard may be added in the proportion of 2 tablespoons to 5galls. of water, and the temperature of the water should not be above 105° F.

Poisoning.

A subject of this magnitude can be only very lightly dealt with in a paper of this nature. As there are between 130 and 150 classified poisons it is quite impossible to deal with the specific treatment for any individual one, and it is proposed, therefore, merely to outline a few general measures of treatment which can be readily applied at home. In corrosive poisoning an emetic is *never* given, whereas in all other poisons this should be the first line of treatment adopted. The corrosive poisons are divided into *Acids and Alkalies*, and if these have been swallowed there is almost always visual evidence of burning of the lips and mouth. The *commoner* acids are spirits of salts, carbolic, phenol, lysol, and most household disinfectants. For these the best antidotes are chalk, whiting, lime water, carbonate of soda, or even plaster from a wall mixed with water in the proportion of 1 tablespoon to the pint. The commoner alkalies are caustic soda, caustic potash, and ammonia. For these the most readily procurable antidotes are vinegar or lemon juice in equal parts of water. In all corrosive poisons olive oil may be given. *In these cases never give an emetic.*

Non-corrosive Poisons.—These cover a very wide range, but are not so frequently met with in general practice, the commonest probably being the various forms of vermin poison, which usually contain some form of arsenic or strychnine. There are many forms of drug poisoning, but these are not commonly met with. *In all of these cases give an emetic immediately.* The commonest emetics are mustard or salt, 1 tablespoon to a tumblerful of lukewarm water and repeated if necessary. If this does not have the desired effect pass the fingers over the back of the tongue and endeavour to produce vomiting by tickling the back of the throat. After vomiting has been produced, any of the following may be given in all cases of poisoning:—Milk (milk and raw eggs beaten together), milk or cream and flour in a thin paste, olive oil, cod liver oil, and strong tea.

All poison cases suffer from severe shock, and it is of paramount importance that they be kept warm. At a later stage stimulants may be given, one of the best being strong black coffee. In cases of poisoning never give alcoholic stimulants. One common article found in most houses may cause poisoning, that is iodine, The treatment for this is simple and easily remembered, simply give ordinary starch mixed to a very thin paste with water.

It is consoling to note that the common species of venomous snakes are few in number. These in order of danger to man are:—(1) The Death Adder, (2) the Tiger Snake, (3) the Copperhead, (4) the common Brown Snake, and (5) the Red-bellied Black Snake.

The mortality following the bites of these species are:—Fifty per cent. for the Death Adder, 40 per cent. for the Tiger Snake, and less than 10 per cent. for the Brown Snake. It is doubtful if the bite of the Black Snake is ever fatal for an adult. Bites from the Copperhead are rare, although this is a very common species, particularly in swampy country.

First-aid treatment is somewhat limited, and varies with the site of the bite. If the bitten part be a limb, a ligature should be applied immediately above the injury. This may be left in position for half an hour, and then loosened until the part becomes pink with the entry of blood, and then re-applied. This procedure can be repeated every quarter of an hour up to 2 hours. If the victim possesses sufficient physical courage he may excise a small area surrounding the fang punctures, and rub in crystals of permanganate of potash. In the case of a bite on the finger more heroic measures have occasionally been adopted. Much research is being carried out in the endeavour to obtain a satisfactory anti-serum for injection purposes. This has been successfully obtained in the case of the Tiger Snake, an antivenene now being available, but this is not of practical use against the venoms of other varieties.

NEW BRANCHES.

During the past month Branches have been formed at Echunga and Yandiah, the respective Secretaries being Mrs. F. Dennis, Echunga, and Miss V. Keller, Booleroo Centre.

EXHIBITIONS OF WOMEN'S HANDICRAFTS.

The General Secretary has been advised that Exhibitions of Women's Handicrafts will be held by the following Branches:—McLaren Flat, 21st March; Morchard, 25th March; Balhannah, 28th March; Karte, 15th April; Parilla, 16th April; Narridy, 7th May; Belalie, 9th June.

WIRRABARA.

The December meeting of the above Branch was held on the 17th, and took the form of a Social Afternoon, being attended by 15 members and 4 visitors.

Economical Breakfast Dishes.

Reading a paper on this subject at the 16th January meeting of the Wirrabara Branch Mrs. G. Kranz said:—Breakfast dishes should be nourishing, sustaining, and quickly prepared. Porridge is one of the cheapest and best breakfast foods. It may be made from oatmeal or wheatmeal. Oatmeal is better for winter use as it contains more fat than wheatmeal. Eggs can be regarded as the second item for the breakfast menu. Being so quickly prepared and usually liked by most people, one can prepare an economical breakfast dish quite simply and yet vary it in so many ways, which is a problem solved. Poaching is one of the lightest forms of cooking eggs. Hard-boiled eggs are indigestible. The fresher the eggs the longer they take to cook. Eggs cannot be too fresh. From 3 to 3½ minutes will set the white. Then there is the usual winter morning's breakfast—fried eggs and bacon. Others again like curried eggs, but they take a little longer.

Curried Eggs.—1 dsp. flour, 6 hard-boiled eggs, 1oz. dripping, 1 small apple, ½pt. stock or water, 1 small onion, 1 small tomato or tomato sauce, 1tsp. lemon juice, 1dsp. curry powder, 1tsp. curry paste, 1tsp. coconut. Method.—Peel apple and onion, and cut into small dice. Mix curry powder, flour, and coconut together. Melt butter in small saucepan and make quite hot, then fry 2 minutes longer. Add flour, &c., stir out lumps, and add the stock or water. Stir over fire until it boils and thickens. Cook gently ½ hour. Then rub through a sieve, return to the saucepan, add lemon juice, and re-heat. Boil the eggs hard, shell them, and cut up roughly. Add to the contents of the saucepan and let them get quite hot. Pour on to a hot dish with a border of rice around. Garnish with slices of lemon and the yolk and white of an egg rubbed through a sieve separately. Other forms of cooking eggs are scrambled eggs, steamed eggs, buttered eggs, but, of course, breakfast dishes cannot consist of eggs alone. A very tasty and simply prepared dish is Potato Cakes and Bacon:—8ozs. potatoes, 3ozs. flour, 2 tablespoons milk, 2 tablespoons clarified fat, ½lb. bacon. Boil potatoes and mash. Season with pepper and salt, add flour, and rub in 2ozs. good clarified fat. Moisten with a little milk, turn out on slightly floured board, roll out about ¼in. in thickness, stamp out in rounds. Melt the fat, and when quite hot put in the cakes and fry until a light brown. Lift out on kitchen paper, and serve on a hot dish, garnish with a roll of grilled bacon.

Breakfast Wonders.—Cut small or mince any cold meat. Make a paste with cold potatoes, 1 egg, salt, and S.R. flour to bind. Roll out and cut with scone cutter. Place meat between two rounds of paste and press edges together. Fry golden brown. Although all these dishes may be very tempting, I prefer the most economical dish of all—a slice of crisp, brown toast with good butter on it, and a cup of good tea. Breakfast is the first supply of the bodily needs for the day's work. It should be simple, as little time can be given to its preparation, but nevertheless nourishing and suited to the needs of those who partake. Apart from the dishes mentioned fruit should be included, especially in summer.

COLD LUNCHES FOR HOT DAYS.

[Papers read by Miss P. Hean and Mrs. H. Kirk at the January meeting of the Auburn Branch.]

It is rather difficult for the housewife to prepare meals that suit the appetites of all, and much more so in summer than in winter. To present a hot mid-day meal when the temperature is at its highest often puts folk off the meal. A well-prepared cold lunch in summer can be made very tempting, such as dishes made from cold meat or fish. Where an ice chest is available cold lunches are much easier to prepare, but country folk who are without a cellar or cool safe have more difficulty in keeping food cool. However the resourceful woman has more ways than one of doing things. For instance, a good way to cool stewed fruit or a custard is to place the dish in a bowl of water with a wet cloth over it. Very often a fireplace in one of the coolest rooms of the house is the best place for this performance. Butter and fresh vegetables can be treated likewise. Cucumbers and beetroot can be freshened up in water. Lettuces may have a wet cloth placed over them or, if desired, put in water to keep them crisp. Jellies can also be stood in water with a wet cloth over them.

RECIPES.

Mayonnaise Dressing.—1 cup of cream or milk, 1 small cup of sugar, 1½ cups of white vinegar, 3 eggs, 2 teaspoons mustard, 1 teaspoon salt. Beat eggs, vinegar, sugar, and cream together, and put 2 tablespoons of butter into a saucepan. When melted add other ingredients. Stir until thick as honey, but do not let it boil. This dressing keeps for 3 months.

Tomatoes and Peas.—Take 6 nice-sized tomatoes, cut off the tops, then take a teaspoon and take out the centre of tomatoes without breaking the outside. Then fill with some cold cooked peas and serve with mayonnaise dressing.

Beetroot Mould.—Two bunches of beetroot, 1 small lettuce, 2 dessertspoons gelatine, 2 cups hot water, pepper, salt, and vinegar. Cook beetroot until tender. Peel, cut into slices, and line a fluted mould with the sliced beetroot. Then fill centre with small dice-shaped pieces of beetroot. Dissolve gelatine in hot water. Pour over beetroot, and allow to set. Garnish with shredded lettuce and sliced tomato. Serve with mayonnaise or vinegar.

Spanish Cream.—½oz. gelatine, 3 eggs, 2 cups milk, 2 tablespoons sugar. Put the milk and gelatine in a saucepan, and put on fire until it dissolves. Beat the yolks of eggs and sugar together. Add to the milk and gelatine, and stir until it just boils. Cool and add the stiffly-beaten whites of eggs. Flavour with vanilla. Pour into a wet mould and set aside to cool.

Mrs. Kirk's paper read as follows:—Some of the most necessary things for the housewife to have in the cupboard for summer are the following articles:—Tins of camp pie, fish, and other meats to be kept, because fresh meat is not always available in the very hot weather on farms Therefore meals can be prepared without the least anxiety with these kept on hand. Gelatine can also be kept, and a variety of dainty and appetising dishes can be prepared from tinned fish and other cold meats. It is also of great value in helping to make a variety in the sweets. The following articles to help prepare sweets should be kept on hand, such as jellies, preserved fruits, junket tablets, and various custard powders and essences. Fresh fruit and vegetables for salads can be procured at regular intervals, for there is nothing more nourishing and tempting when it is very hot than plenty of salads both vegetable and fruit and all kinds of stewed fruits which have become quite cold. Sometimes folk prefer vegetables left whole and cut them up themselves, such as tomato, cucumber, and onion.

Home-made Camp Pie.—1lb steak, 1 cup breadcrumbs, ½ nutmeg, ½ cup water, pepper and salt. Mince steak well, mix all together, put in mould, steam for 2 hours, and put in a cold place until perfectly cold.

Meat Loaf.—From stock, soup, or gravy, with small piece of meat. Take 2 cups of any liquid available, and bring to the boil, adding 2 dessertspoons of gelatine. Stir until dissolved, then remove from the fire and allow to cool. When the mixture begins to set, add 2 cups of any minced odd meats after mixing all together. Place in mould to set. When serving cut in slices and garnish with parsley.

Sheep Tongue Shapes.—2 dessertspoons of gelatine, 3 sheep tongues, 2 cups of hot water or stock. Boil tongues until tender, skin, and slice finely. Arrange nicely in round cake tin. Fill tin with slices, then dissolve gelatine in clear hot stock or water, add pepper and salt, pour over tongues, and allow to set. Turn out and garnish with lettuce, tomato, and parsley.

Salmon Mayonnaise.—1 small tin salmon, 1 lettuce, 3 tomatoes, 1 onion. Mayonnaise:—2 hard-boiled eggs, ½ cup of milk or cream, 2 dessertspoons of sugar, 1 tablespoon of vinegar. Open tin of salmon on a soup plate, break it up with a fork finely, and then divide in 3 parts, placing one part in a salad bowl, then a layer of onion, then a layer of tomatoes, and then a layer of lettuce, and then continue the other two parts likewise until the bowl is filled. Make the mayonnaise dressing and pour over it, and cut 1 egg in rounds and place on top. Stand for a few minutes, and it is ready for use.

Salmon in Jelly.—2 dessertspoons gelatine, 1 small tin salmon, 2 cups hot water, juice of 1 lemon, 1 hard-boiled egg, pepper and salt. Take tin of salmon and open in basin, break it up with a fork finely, then dissolve the gelatine in hot water, adding juice of lemon, also pepper and salt. Mix all thoroughly together. Wet a round mould, and place slices of hard-boiled egg at the bottom, then pour the mixture in very gently, and allow to set. Garnish with shredded lettuce, slices of tomatoes and lemons. Serve with vinegar.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, 1936.

Dairying, at Strathalbyn, Thursday, 21st May (Mr. Reg. Sissons, Strathalbyn, Secretary).

River Murray, at Block E, Thursday, 18th June (Mr. J. C. K. Brigham, Box 65, Renmark, Secretary).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Dried Fruit Beetle.

Specimens of insect infested currants were forwarded by the Ramco Branch of the Agricultural Bureau to Mr. A. G. Strickland, M. Agric. Sc. (Chief Horticultural Instructor), who says the larvae present in the currants have been identified by Dr. J. Davidson of the Waite Institute as those of the so-called dried fruit beetles. These insects and their larvae occur on flowers and fruit in orchards (such as fermenting figs, split stone peaches, &c.), and on fruit in drying trays or on racks.

These larvae are not those of the more troublesome dried fruit moths, and infestation of the fruit with such is not usually serious, as in the case of the moth larvae.

As the insects in question (dried fruit beetles) will breed in fermenting fruit in the open—whether on the ground or on the vine—it seems likely that the infestation has arisen even before fruit was taken to the drying ground. This season has been remarkable for the heavy rains which occurred in January, and which caused splitting, mould, and fermentation in currants on the vines. Under these circumstances, it is probable that the orginal infestation occurred much earlier in the season; it is good policy to cull out mouldy, split, or fermenting bunches before proceeding with drying. At this stage it is difficult to suggest any well defined measures of control; it is desirable, however, to speed up the drying as much as possible. Once fruit is in the case and treated with fumigant, such as Erinol, the infestation should not extend.

A general clean up of all rubbish on drying greens, in sheds, sweat boxes, &c., is essential, so that there will be no chance material in which the pest can breed.

Smut in Oats.

Mr. R. C. Scott (Supervisor of Experimental Work) has advised the Secretary of the Laura Bay Branch of the Agricultural Bureau that if oats badly affected with ball or loose smut should be used for seed, the smut spores attached to badly infested oat grains may be deeply lodged in the crevices or under the husk, and therefore are not readily attacked by the pickle used.

Consequently no treatment is likely to be effective in entirely destroying the disease, although the trouble will be lessened because of the destruction of the spores adhering to the seed coat. It is therefore not advisable to utilise badly smutted oats for seed, but if this is absolutely necessary, pickling with formalin is more effective than the other fungicides.

The Champion Wheat Crop.

At a special function at Yeelanna on 27th March, Mr. W. H. Watkins received from the hands of the Secretary of the Royal Agricultural Society (Mr. H. J. Finnis) the Championship Challenge Shield donated by the Society for the best wheat crop grown in the State-wide competitions conducted by the Department of Agriculture.

These competitions began in 1927, and competitors in the Flinders District on Eyre's Peninsula have succeeded in securing "placed" positions in six out of the nine Annual Competitions, and the six crops were all grown at Yeelanna. Messrs. Smith Bros. came third in 1927; Messrs. Aikenhead & Treloar, third in 1929 and second in 1931; Mr. R. R. Wilson, second in 1932; Mr. W. H. Watkins, third in 1934 and first in 1935. The residents of the Yeelanna district have reason to be proud of the distinction won by Mr. Watkins after such persistent efforts by their competitors to gain the major prize. The Shield will remain at Yeelanna until it is won by a competitor of some other district.

Hoary Cress.

A specimen of this troublesome weed has been sent from Paskeville for identification. Mr. Spafford has advised that if there is only one patch on the farm every effort should be made to eradicate it, and he suggested that the services of the District Agricultural Instructor should be sought in order to discuss the problem on the spot.

Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of the following publications:—

"Herbs," Ministry of Agriculture, England, Bulletin No. 76. Price 1s. net.

"Australian Tea Trees and Their Economic Value," Bulletin No. 14. Price 6d. Published by Technological Museum, Sydney, New South Wales.

"Cultivation of the Australian Nut," Bulletin No. 2. Price 1s. Published by Technological Museum, Sydney, New South Wales.

AGRICULTURAL INQUIRIES.

Spontaneous Combustion in Meadow Haystacks.

What is the cause of spontaneous combustion in meadow haystacks?—Reply by Mr. W. T. Rowe, Director of Chemistry.

Spontaneous combustion occurs when a substance becomes heated to a point above its ignition temperature, then by some means air is supplied.

Spontaneous combustion in haystacks is due to the chemical combination of some of the constituents of the material with atmospheric oxygen, and unless due provision be made for the escape of the heat, its accumulation may raise the temperature to a dangerous degree. If the heat which is produced is prevented from being dissipated, the temperature will go on rising gradually. As the temperature rises the vigour of the combustion increases, and more and more heat is produced in a given time. Then the temperature rises more and more rapidly, until finally the combustible matter takes fire without the application of external heat, provided air or oxygen is in some way supplied.

According to Dr. Von Schwartz in "Fire and Explosion Risks" in grass, clover, hay, &c., the vegetable cell retains its vitality for some time after the hay has been cut; respiration continues and is accompanied by the generation of heat. To this heat must be added that produced by the vital activity of the never failing spores and germs of micro organisms; and finally seeds in germinating also develop heat.

None of these sources furnish heat that is appreciable so long as the conditions allow the heat to be dissipated. So soon, however, as the hay is piled up in such a manner as to retain the moisture present (a prime essential for the inception of the subsequent processes), then the escape of heat is prevented, though it remains harmless while a sufficiency of moisture remains, or is afforded a means of escape, or finally so long as the mass is pressed tightly enough to prevent the penetration of air into the heated portions of the stack.

Field Crickets.

In reply to a question from the Penola Branch on the best method of destroying crickets, Dr. J. Davidson, M.Sc., of the Waite Institute, states that the common black field cricket (*Gryllus servillei* Sauss.) sometimes occurs in large numbers during hot, dry weather. The eggs are laid on the ground under the cover of debris; the newly hatched insects gradually increase in size and moult at least five times before becoming adult.

The insects are night feeders; the males make a loud, piercing, singing noise, which is produced by the rubbing action of the overlapping wings. The insects may be destructive to pastures, field and garden crops; vines and the buds of orchard bushes and trees may be also damaged.

The control measures will depend upon the character of the area infested. The use of poison bait or spray as recommended for grasshoppers (see *Journal of Agriculture*, South Australia, 1934, vol. 38, p. 623) is the control measure usually employed.

NOTE.—The greatest care must be observed in the use of poison bait, owing to the danger to children and domestic animals.

The reference to the poison bait is as follows:—

The poison bait method is widely used. A bait consists of an inert carrier, a poison, and an attractive substance. Bran is a useful and efficient carrier, but other convenient materials, such as chaff, chopped fodder, or sawdust may be used where bran is not available. The carrier should break readily into small pieces when the bait is distributed; it must not deter the insects from feeding on the bait. Bran has many advantages as a carrier, and its high efficiency offsets its cost. Experiments should be made with suitable local materials.

Arsenical poisons have given the most satisfactory and consistent results; Paris green and sodium arsenite are generally used. The soluble forms of arsenic compounds kill the insects quicker than the insoluble forms. The solubility of certain compounds in 100 parts of cold water are given below:—

White arsenic (arsenious oxide), As_2O_3	1.2 parts
Sodium arsenite, Na_2HAsO_3	Very soluble
Sodium arsenate, $Na_3AsO_4 12H_2O$	26.7
Calcium arsenate	Insoluble
Lead arsenate	Insoluble

With soluble poisons the solution of the poison is poured over the bait carrier and thoroughly mixed; with insoluble poison the bait should be mixed dry with the carrier and then made into a mash with an appropriate amount of water.

The attractive agent in the bait greatly increases its efficiency. The evidence regarding the value of the use of molasses is conflicting; where this material cannot be obtained it would appear to be justifiable to use the bait without it. In addition to being attractive to the insects, molasses assists in keeping the bait moist for a longer period. Damp baits are more attractive than dry ones; salt is sometimes added to baits in order to assist in keeping them damp.

Other substances have been used in baits as attractants, such as crushed fruits. Further experiments are necessary on this aspect of baits.

The following formula has proved to be an effective bait in Australia:—

Arsenite of soda	½lb.
Molasses	4lbs.
Bran	24lbs.
Water	2½galls.

The arsenite of soda is dissolved in the water and the molasses added to the solution. The mixture is sprinkled over the bran, the whole being thoroughly mixed to form a crumbly mash. The amount of arsenious oxide present in the arsenite of soda is important; the formula refers to an arsenious oxide content of 80 per cent.

The bait is scattered over an area of about 30ft. wide in front of advancing swarms of hoppers. The amount of bait required per acre will vary with the character of the area. About 10lbs. of bait (dry) should be sufficient, but in practice the amount used may be greater than this; if laid too thickly, there is undue wastage of bait. The risk of poisoning stock is negligible if the poison bait is spread thinly as directed. Operators handling poison bait must observe commonsense precautions. Baits should be spread early in the morning; the hoppers become more active later in the day as the temperature increases. On cold days baiting is not so effective, since the hoppers are sluggish.

VETERINARY INQUIRIES.

[Replies supplied by the veterinary officers of the Stock and Brands Department.]

Worms in Sheep.

Hon. Secretary, Agricultural Bureau, Narrung, asks several questions relating to worm infestation in sheep.

(1) In what form does the worm enter the bowels of a sheep?

Reply—The only worm of sheep, the life history of which has been discovered is the *Haemonchus contortus* (wire worms) found in the fourth compartment of the sheep's stomach.

In the case of the *Haemonchus contortus*, it is the third larval form which has developed on the grass and in the soil which is swallowed and which, after being in the stomach for a month, becomes the fully matured worm. The female lays eggs which are passed out and which, if sufficiently developed, will produce the first larval stage of development of the worms in the soil. Two further stages (second and third larval stages) take place, but only after the third stage of development are the larvae capable of further development in the stomach of the host, *i.e.*, if the immature worm is swallowed before it reaches the third stage of development, it is not capable of developing into a mature worm.

(2) If "wormy' sheep were drenched and put in a fresh paddock, would the droppings from those sheep be harmful to other sheep not affected with worms?

Yes, because the eggs in the droppings if mature would develop further larvae.

(3) How long would a paddock that has had "wormy" sheep in have to be spelled (that is, sheep kept out of it) before it would be free of worms or clean to put fresh sheep in

It is generally considered that at least 12 months must elapse before such pasture could be freed of infection with worms. This means that no cattle, sheep, or goats should be allowed on it during that time, but it is pointed out that it is doubtful if any sheep free of worms could be found, and under favourable conditions of temperature and moisture such country would soon become re-infected.

Grease in Horses.

E.V.H., "Frances," has horse with oily fluid oozing from the skin just above the hoofs.

Reply—The condition is known as "Grease" and is very difficult to cure. The following treatment is advised:—

(1) Give the following drench after starving for 24 hours:—Raw linseed oil, 1 pint (draught horse 1½ pints); oil of turpentine, 2ozs.

(2) Subsequently give one tablespoonful of Fowler's solution of arsenic in a small damped feed night and morning for 14 days. Stop for one week, and then repeat for another 14 days.

(3) Apply the following dressings locally and alternately every four to five days:—

(*a*) Whale oil or linseed oil, 20 parts; powdered sulphur, 4 parts; oil of tar, 1 part (get oil of tar from chemist).

(*b*) Lead acetate, 1oz.; zinc sulphate, 1oz.; copper sulphate, 1oz.; water, 1 pint. (Before starting to apply this lotion, wash area with warm water and soap.)

Pigs Weak in Back.

Secretary, Chapman Bore Agricultural Bureau, Murray Bridge, reports pigs weak in back, suddenly fall to the ground when walking.

Reply—It is suggested that the supply of skim milk to the sow be increased, and, if possible, a proportion of it be fresh whole milk for 7-10 days. Further, if the young pigs are confined to a sty they should be allowed out.

The addition of a boiled rabbit to the ration occasionally will help.

The following mineral lick should be supplied:—Agricultural lime, 2 parts (it is essential that it be thoroughly air slaked); common salt, ½ part. Add 2lbs. to every 100lbs. of grain used.

Questions submitted at the Upper South-Eastern Bureau Conference, Bordertown, 15th April.

Entero-toxaemia.

Is vaccination against entero-taxaemia worth while?

Reply—The entero-toxaemia vaccine affords a definite protection to sheep against this disease, and the latest annual report of the Council for Scientific and Industrial Research states that "Field observations continue to indicate that vaccination is a successful means of prevention, and the number of sheep inoculated last season again showed an increase." For any sheepowner whose flocks are subject to losses from this disease it is certainly worth his while to employ the vaccine, which is relatively low in price, and the saving of but two or three animals will pay for the cost of the vaccination.

Sheep Dips.

Are there any regulations regarding the dimensions of sheep dips?

Reply—No. The regulation relating to the dipping of sheep in this State prescribes that all sheep within the proclaimed dipping area "must, between the period of 1st September in every year and the end of the following January, be dipped by wholly immersing them for a period of not less than one minute in an arsenical dip containing not less than 0.1 per cent. of arsenious oxide."

To regulate for any specified size of dipping bath to be used would not necessarily ensure that the above requirements were effectively carried out, and as this can be done in baths irrespective of their size (so long as they are big enough to permit of wholly immersing the sheep), it is left to owners to use whatever size of bath they wish in order to facilitate the work of dipping.

Itch in Horses.

What is the cure for itch in horses?

Reply—If a properly constructed horse dip is available, the animals can be stood for 15-20 minutes with their legs immersed in a 1 per cent. solution of any of the coal tar disinfectants (such as lysol, cresol, &c.). There are on the market a number of proprietary preparations of these, and if any of them are used, the strength of the dipping solution should be that recommended by the manufacturers. It is important when preparing the dipping solution to make certain that the disinfectant preparation will make a uniform and permanent admixture with the water beng used, and this is best done by first making a test with small quantities of the disinfectant and the water. If the water is found to be too hard to make a perfect mixture, it will have to be softened by the addition of washing soda. This perfect admixture between disinfectant and water is necessary to prevent any scalding of the animals' legs taking place.

While the animal is in the dip, a rag mop on the end of a stick should be used to work the solution thoroughly through the hair on the legs and on to the skin. The roots of the hair of the mane and tail can at the same time, if necessary, be treated by applications to the dipping solution.

The dipping should be repeated three or four times throughout the year.

Where this dipping process cannot be carried out, the animal's legs from the hoof-tops up to the knees and hocks can be given a good scrubbing with disinfectant solution as above, and then, after drying them out with clean rag, a little of any of the following dressings rubbed well into the roots of the hair:—

(1) Raw linseed oil and kerosine, equal parts.
(2) Raw linseed oil and turpentine, equal parts.
(3) Raw linseed oil, 1 pint; lysol, 1oz.

Two or three dressings with any of these at intervals of three or four days will usually suffice.

If necessary the mane and tail regions can be similarly treated.

It is advisable also, in addition to treating the animals, to clean up and disinfect the stables and harness.

SUMMER TEMPERATURES ON EYRE'S PENINSULA.

The Mangalo Branch asks:—"Are the summers on Eyre's Peninsula getting cooler? Old residents of the district state that there has been a steady decrease in burning weather during latter years."

This question was submitted to Mr. E. Bromley (State Meteorologist), who says:—"Temperature records at Kyancutta, the only inland Climatological Station on Eyre's Peninsula, are too recent for any comparisons to be made. I find, however, from an examination of the Adelaide records, which extend over a period of 78 years, that in both January and March the mean maximum temperature for the last 39 years (1897-1935) shows a falling off in temperature of 1½ to nearly 2 degrees from the first period of 39 years (1858-1896). In the other summer months, November, December and February, however, the temperature means for the two periods are practically the same, February showing a slight increase in the second period (1897-1935). The records certainly do not show a steady decrease in temperature in more recent years, in fact, the individual hottest months for November, December, January, and March occurred in the latter period, the most recent being the unprecedented hot March of 1934."

FIG TREES ON EYRE'S PENINSULA.

Specimens of fig fruits and leaves showing signs of withering were forwarded from the Petina Branch of the Agricultural Bureau to Mr. R. Fowler, of the Blackwood Experimental Orchard, for an explanation of the trouble. Mr. Fowler says:—

"From inquiries, I find that the average rainfall at the nearest recording station to Petina is only approximately 10in. to 11in., and I take it Petina would be about the same. I should imagine, therefore, that the very low rainfall would most likely account for the difficulty with the figs. While the fig will grow in dry situations, it must have sufficient moisture to support and preserve the foliage, if it is to produce and ripen its fruit. The condition of the leaves and fruit submitted appears to indicate lack of growth in the tree, no doubt due to lack of moisture. As with other fruits, the fig needs plenty of moisture, but not too much. If the soil does not retain the needed amount, naturally it must be supplied by irrigation wisely administered.

"There are instances of barren fig trees which persist in dropping their untimely figs year after year. This may be due to variety, locality, or lack of pollination in the case of the Smyrna type of fig. The remedy is grafting over barren trees with suitable scions, or in the case of the Smyrna, introducing the fig wasp. I note, also that the fig tree in question is only 6 to 7 years old. Young trees sometimes persist in the habit of not maturing their fruits for some years, but improve with age. I would suggest in this instance that the tree be liberally watered and mulched during the next season, and it might also be advisable to try the effect of pollenization with fig wasps The wasps can be supplied from our Experiment Orchards."

ACTIVITIES AT ROSEWORTHY COLLEGE, 1934-35.

PART III.

PROGRESS IN THE IMPROVEMENT OF THE BAKING QUALITY OF SOUTH AUSTRALIAN WHEAT.

[By ALLAN R. CALLAGHAN, D.Phil., B.Sc. (Oxon.), B.Sc.Agr. (Syd.), Principal, and E. J. BREAKWELL, B.Sc.Agr. (Syd.), Plant Breeder.]

THE PROBLEM.

Three years ago, a programme for the improvement of the baking quality of South Australian wheat was quietly initiated at Roseworthy College. In the last 12 months there has been a sustained attack on the quality of Australian wheat, and the matter has received the publicity its importance warranted. Indeed, so much has been written and discussed lately, relative to the problem, that the subject has become hackneyed.

Very varied interests are closely associated with the wheat industry, and the problem has naturally been approached from different angles. So that in spite of the fact that much has already been said about the baking quality of our wheat, it has chiefly emanated from diverse interests; the many points of view have tended to cloud the issue, and farmers for the most part have found it difficult to become truly acquainted with the facts of the position. For this reason an endeavour is made herein to review the whole field, summate the causes and the effects, and indicate the investigations necessary as correctives.

DEFINITION OF QUALITY.

It is necessary at the outset to define quality. The baking quality of wheat has not concerned the grower for the simple, understandable, and excusable reason that it has not meant extra returns to him. It is equally understandable that the average man concerned with wheat should find it difficult to fathom this sudden onslaught on baking quality when hitherto, grain was judged on its appearance and weight. The miller, on the other hand, must study baking quality, for he produces flour for bread making. In consequence, the baker insists on the miller supplying him with satisfactory flour for his purpose. In turn, the baker must follow the dictates of the consumer, so that actually the definition of quality rises as a direct issue from public demand. That demand in the case of bread is for a large well-shaped loaf, good in colour and texture, with crisp eatable crust; so that the baking quality of wheat is the capacity of the flour milled from it to produce loaves of good volume, shape, and texture.

It is pardonable to ask why one variety of wheat should be capable of produring a better loaf of bread than another. Unfortunately the reason is not obvious, and the differences that do exist are not easily measured. In the process of milling the outer skin and embryo of the grains are removed and go to form the by-products—bran and pollard. The central starchy portion is responsible for flour, and the chief constituents of this portion of the grain are starch, gluten and sugar. Of these three, the gluten is by far the most important from the point of view of quality. The gluten is the protein or nitrogenous element of the flour, and is present to the extent of usually about 10 per cent. Now quality, or strength, as it is often called, is intimately bound up with both the quantity and quality of the gluten present in the flour. In other words, the capacity of a certain flour to produce good, well-shaped, nice-textured loaves of bread is very largely dependent upon both the quantity and the quality of the gluten it contains. This is because the gluten is mainly responsible for the ability of the dough, made from the flour, to rise as a result of the production of carbon di-oxide during fermentation, and the ability also of the dough to hold this carbon di-oxide as it is formed and so maintain a puffed-up condition until it is properly baked.

To make good bread a dough must have good gas-producing properties, but at the same time it must have high gas-retentive powers. The gluten is actually responsible for the physical properties of the dough which give it the necessary elasticity and distensibility, combined with the power of gas retention.

Another important point is that the gluten of flour is responsible for its water-absorbing ability, and the water absorption of the flour in turn determines to a large extent the number of loaves that can be made from any given quantity.

All these points concern the gluten and its quality, but one other consideration concerning the value of flour is its diatatic activity which governs the rate of gas production by the yeast. The initial gassing power is dependent chiefly upon the sugar present in the flour. The latter aspect need not concern us greatly, except that it should be realised that some Australian wheats are considered too low in maltose.

It can be said that the chief consideration in measuring the baking quality of our wheats is to assess the quantity and quality of the gluten present, and because of its very important physical properties, its quality is of especial significance. This long definition of what determines quality in our wheat is necessary in order to understand the reasons for our present position, because, undoubtedly, the difficulty of measuring the relative qualities of samples has been the most serious handicap to the plant breeders of the past.

HOW THE PROBLEM ORIGINATED.

When two varieties of wheat are crossed in an attempt to breed a new variety, the heritable characteristics of both are intimately and completely intermingled, so that the grain obtained from the cross produces a plant bearing the characters of both parents. The many grains from this plant will produce plants entirely different, because the characteristics of the two original parents will be segregated into various and different combinations. Two years after the cross is made selection is possible from the plants so produced, but every plant is different, and must be kept separate and quite apart from others. Normally its potentialities for yield and its general agronomic characters can be judged to a reasonably accurate degree on appearances, but not so its quality.

In the past, it was necessary to proceed for several generations before sufficient grain from any particular selection was available to test for quality for the reason that no satisfactory method other than a baking test was known, and for this a millable quantity of grain was required. In short, this disability precluded the possibility of selection on scientific lines and, accompanied by a growing tendency of neglect quality and select for yield alone, led to the production of high-yielding strains with indifferent quality.

This latter development of the yield complex is quite understandable, and to make it clear, a retrospective glance over our wheat-breeding experience is helpful. When William Farrer commenced wheat breeding in Australia he paid special attention to quality, and in the earliest years of his work, selections were not encouraged or persevered with unless they possessed satisfactory quality. In fact, when the great pioneer variety, Federation, was selected and first grown in the breeding rows before it was named, it was considered to be rather too weak in flour strength, but its outstanding capacity to yield, combined with admirable agronomic characters, such as a strong straw and good grain-holding ability, outweighed the fact that it was hardly as good as Farrer required from a quality point of view. Federation, as is commonly known, revolutionised wheatgrowing in Australia, and made subsequent development possible and profitable.

Actually, its production also revolutionised the outlook, for from then on it appears that quality was given far less attention, due to the fact that wheats such as Federation were being feverishly sought after on the basis of their yieding ability alone. Yield became the primary consideration, and systematic selection on the part of the plant breeder was devoted to yield to the almost, if not entire, neglect of quality.

In substantiation of this argument one need only scan the pedigrees of the leading wheats of Australia. On the most recent figures available it was estimated that the 20 leading wheats in their approximate order are Nabawa, Ford, Free Gallipoli, Ranee, Waratah, Gluyas, Aussie, Currawa, Yandilla King, Gluclub, Federation, Ghurka, Bena, Bencubbin, Sepoy, Rajah, Noongar, Canberra, Turvey, and Penny.

All of these wheats, with the exception of Ford and Bena, are classed as weak, whilst several such as Free Gallipoli, Waratah, Gluyas, Currawa, Gluclub, Ghurka, and Noongar are very weak. Only in four of the 20 leading wheats, namely, Nabawa, Federation, Ford, and Bena, have parents with any pretensions to quality been used, and a measure of success has been obtained only with Ford and Bena. *Incidentally it might be mentioned that Ford was bred and released from Roseworthy Agricultural College.* The value of Ford has been recognised all over Australia and especially excellent reports have come from New South Wales, but seldom is due credit given to Roseworthy College for its creation; in fact its origin in most cases is left to inference which is not always fair.

The wheats which are causing most trouble, and likely to cause more, are in most cases of similar origin, and in the outstanding cases the trouble is traceable to a clubhead ancestor. Take Free Gallipoli, Currawa, Ghurka, and Gluclub. These few are certainy among the weakest quality wheats grown to any extent in Australia, and in all cases the clubhead type has been used in their breeding. Seek the motive behind the choice of the parents of such varieties as Free Gallipoli (Clubhead x Yandilla King) and Gluclub (Gluyas Early x Clubhead), and it is apparent that quality was given no consideration whatever.

From these remarks it should not be inferred that the policy of breeding for yield alone is the one explanation for the present position, nor that the policy is inexcusable. In fact, it was born in the early days by the success of high-yielding wheats like Federation, nurtured by the forgivable desire on the part of the farmer for increased monetary returns, and matured by the plant breeders who followed the dictates of demand. Moreover, it is possible that there is a linkage between the factors which contribute to high yield under our dry short-seasoned conditions and those which determine quality. If this is so, it will be necessary to handle large numbers of crossbred lines if an association of high quality with high yield is to be discovered.

THE EFFECTS OF MODERN DEVELOPMENT.

Until recent years there was absolutely no incentive to seek better quality wheats. Australian wheat was eagerly bought on the world's market, and in fact brought higher prices than the best Canadian. Our wheat has always been noted for its excellent colour, bloom, and dryness, and for the flavour it imparts to bread made from it. These characteristics, combined with its only very moderate quality, made it especially valuable for blending with the strong Manitoba wheat which in England is rarely used without being blended with weaker wheat. Fortunately, the other characteristics of our wheat made up for the deficiencies in the Manitoba, and, consequently was preferred to other wheats for the purpose of blending.

In recent years several factors have, however, altered the outlook, and one of the chief is that the universal use of bleaching by millers has reduced the significance of colour to a minimum, and thereby deprived Australian wheat of one of its former most valuable attributes. Hand in hand with this, the enormous increased production of soft European wheat has aggravated the position, and the demand for soft white wheats of the Australian type has accordingly decreased considerably.

Another factor is that mechanical mixing of dough has also been universally accepted and greater strength, or better quality, is necessary to stand up to the mixing so given. Flour from Australian wheats is often insufficiently strong to stand up to the modern methods of the bakehouse. The obvious reply is that Australian bakers make good bread from our wheats, but in answer again to this there are two items worth consideration. The first is that Australian wheat sold overseas is eventually used by bakers unaccustomed to baking from weak flour wheats, and unfortunately the task of making them change their ways in order to use more Australian wheat is out of the question. In other words, they are the customers and they have the right of stipulating what they want.

The second reason why our bakers succeed so well with Australian wheat is that they have first pick, and millers have developed keen selective methods, and undoubtedly buy for local requirements the best quality wheat that is grown here. This selection of all the best for home consumption naturally reduces quite considerably the quality of our f.a.q. wheat shipped overseas.

The change in outlook for Australian wheat brought about by the above-mentioned factors has been greatly exaggerated by the increased growth of wheats such as Free Gallipoli, Waratah, Gluclub, Ghurka, and other very weak wheats, the biggest proportion of which is exported, thereby tarnishing the name of Australian wheat. In fact, it appears that as a result of a complacent attitude, little by little the quality of our harvest has regressed. The regression has been most serious where the very weak varieties have dominated a State's harvest, and the spectacle of Victorian wheat not only bringing a lower price but being almost unsaleable is, undoubtedly, due to varietal influence rather than to those of environment.

IMPROVING THE QUALITY OF SOUTH AUSTRALIAN WHEAT.

1. The Exclusion of Very Weak Wheats.

Present indications are that our f.a.q. wheat must be improved in quality to the extent at least that the very weak flour wheats are excluded. The aim should be not to produce wheat of the strong flour class so much as to produce a sample of satisfactory strength to our customers.

The thing that must be checked immediately, and avoided in the future, is the indiscriminate and extensive growth of very weak flour wheats.

For nearly three years Roseworthy College has been face to face with the problem, and the work of improving the general quality standard of South Australian wheat has been one of major consideration. The College has openly condemned and ceased to distribute the seed of certain varieties, and in this regard the splendid response by farmers has been very commendable. The requests for seed of very weak flour varieties has diminished in spectacular fashion just as the demand for better quality wheats has increased, and one cannot help admiring, with a sense of pride, the loyalty of the farmer to the cause. It is certain that all the best farmers of the State will respond to any efforts which are being made, and might be made in the future, to curtail the growth of varieties of inferior quality.

2. Development of New Varieties.

The development of future varieties for cultivation in this State is chiefly the work of the Agricultural College at Roseworthy, and a brief outline of what is being done will indicate that the problem has not been neglected.

a. Testing of Existent Varieties.—New varieties from other States and countries are regularly introduced to the College and tested for yield and quality. To date, the two outstanding introductions are Dundee and Baringa, both of which show definite promise. The former possesses a baking quality of a higher order than any other widely grown Australian variety, and it combines this feature with desirable agronomic characters. Results at the College last season indicate that it is at least equal in yield to other leading varieties. It is being tested by farmers in many parts of the State, and reports so far have been encouraging.

Baringa undoubtedly possesses yielding ability, and was first in its class in the College Field Trials in 1934, and with the substantiation of these results in subsequent trials it will be recommended to farmers. Although the quality of this variety, in the true sense of the word, is only fair, it has certain characters, such as high stability of the dough and water absorbing capacity, which make it a valuable component of a blend, and millers in New South Wales are paying a slight premium for the wheat.

Other varieties of known high baking quality have been tested for yield, but results show them to be too deficient in this respect to warrant their cultivation. There are still some few varieties from other States which have yet to be tested, and it is possible that work in the future may reveal certain varieties which might well replace, in some districts at least, the poor quality varieties now being grown. Improvement in the general baking quality of South Australian wheat to be effected along these lines, is, however, necessarily restricted. The value of variety surveys is of an indirect nature in that they are likely to reveal suitable material for crossbreeding. For example, recent introductions from America and South Africa, although of no direct commercial value, combine high quality with disease resistance, and are being extensively used in the breeding work.

The cereal collection, which includes many hundreds of varieties, is under review, and all varieties possessing some desirable agronomic characters are being studied intensively or baking quality. Some of these varieties, particularly the older ones, which have never before been studied from this aspect, might possibly possess certain characters such as high gluten quality, stability, or high maltose content, which would make them valuable for cross-breeding purposes.

b. Selection for Quality Within Existent Carieties.—For the most part stability of varieties is an accepted thing, and in most cases where varieties have been in cultivation for several years following release from the plant breeder they breed true. There are exceptions to this rule, however, especially where the initial steps taken in the fixation of the variety have aimed at developing a type rather than a pure line, or where inordinate haste has dominated the breeder and the new strain is released before it is properly fixed. Examples are numerous, and in South Australia there are two of outstanding importance in Ford and Sword. These varieties exhibited appreciable variation in morphological characters which were readily detected by the naked eye. Accordingly it was both logical and sound to assume that similar variation existed in characters not so easily discerned, an important example being baking quality. This led to the initiation of strain selection in 1933, and the work has met with considerable success. Large numbers of single plants of these varieties were harvested and tested for quality by means of the Pelshenke Test, and it was found that there was a wide range in the quality of the individual plants, some of them giving a figure appreciably higher than that of the commercial sample. The remnant seed from the highest quality plants was sown in 1934, and further quality tests were carried out with the resultant grain from the 1934 harvest.

The quality figures for the individual lines so harvested, agreed closely with those of the parental single plants obtained from the previous year. The following figures substantiate this point:—

Selected Strains of Ford.—Pelshenke Figures for 1933 *and* 1934.

	1933.		1934	
Line.	Range.	Mean.	Range.	Mean.
Q	88-105	97	63-70	67
H1	90-128	108	77-78	77
T1	65-82	74	53-61	57
I1	34-72	62	40-68	52
F1	77-88	80	57-70	65
Y1	90-112	100	73-84	77

Over 40 lines of Ford are being grown at the College this season; these will yield sufficient grain for baking tests as well as yield trials. Up to the present it has not been possible to assess the actual difference in baking quality between the worst and the best of these lines—the Pelshenke figures range from 50 to 85—but as a result of the work, at least a slight improvement in the baking quality of this variety is highly probable. Gluten washing tests with the lines have revealed a considerable range in the gluten quantity, and no significant correlation between the Pelshenke figures and the gluten content of the lines exists; this indicates that inherent gluten quality is variable as well as the capacity of the line in producing quantity of gluten. Furthermore, it is possible that more detailed study of the various lines, which will be possible with up-to-date equipment, will detect significant differences in stability and diastatic activity. In this manner such tests may lead to the sorting out of strains which will result in improvement along these lines.

Sword, another variety showing variation, is more prolific than Ford in most parts of the State, but it lacks the disease resistance and baking quality of the latter. A pleasing feature of the work to date with Sword is that there are definite indications that a superior srain has already been isolated. For two years in succession this strain has given a Pelshenke figure equal to that of Ford, and the gluten washing test has shown that it possesses considerably more gluten, and a gluten of higher quality than that of the commercial Sword.

Of course, it may so happen that the superior quality strains produced by this method might be inferior in yield to the commercial varieties. Before a definite statement may be made in this respect another two years' trial will be necessary, but results obtained so far are hopeful.

The improvement of the baking quality of existent varieties is restricted to those varieties which have not been properly fixed, and which have some pretentions to satisfactory characters from the quality point of view. Beyond Sword and Ford, there are no varieties of significance to South Australia worthy of consideration. The economic importance of these two varieties, however, is sufficiently great that even a slight improvement in their baking quality should reflect favourably on the quality of South Australian f.a.q. wheat.

*c. **Breeding New Varieties.***—The breeding of new varieties of improved baking quality by cross-breeding is the method by which most progress will be accomplished.

A brief outline of the procedure adopted may help to elucidate the discussion which follows. The parents of each cross are first carefully selected. A combination is sought which will, theoretically, produce a wheat as nearly perfect as possible. There are a number of high quality wheats at the disposal of the plant breeder, but unfortunately too few of these are even fair agronomic types, and if insufficient consideration is given to the agronomic characters of both parents, success is very problematical. Most of the crosses at the College in the past three years have been made between such high quality wheats as Pusa 4, Dundee, S.H.J., Carrabin, Dindiloa, and others which possess some desirable characters, and the common low quality high yieding varieties, such as Sword, Ghurka, Gallipoli, Waratah, Nabawa, &c.

No selections are made until the second year, when a varying number of plants, according to the general appearance of the cross, are selected. These each give rise to a line in the third year, and every line possessing desirable agronomic characters is tested for quality by the Pelshenke test. If a line falls below a fixed standard of quality it is rejected. Seection for quality, yield, disease resistance, and so forth is continued to about the sixth generation, by which time the lines are sufficiently well fixed, and testing for yield on a field scale commences.

As already indicated, until quite recently the wheat breeder was seriously handicapped for the want of some measure of quality of small samples, but in 1930 a German worker published a paper outlining a whole meal fermentation test designed to guide the work of a plant breeder in sorting out wheat selections on a quality basis. This test, which is commonly known as the Pelshenke test, endeavours to measure both quantity and quality of gluten, combining the two in such a way as to express the comparative baking qualities of the wheat samples under review.

This test has been fully and carefully exploited at the College, and although it is not infallible, it is definitely a very useful and indispensable guide for the plant breeder. It is more a measure of quality of gluten than quantity, but using it and a gluten washing aparatus, both items can be independently measured with some degree of accuracy. The whole meal fermentation test enables the plant breeder to exclude with certainty the very weak quality wheats.

As a direct contrast to the older methods, the College has now adopted the procedure of harvesting large numbers of plants from the second generation populations, testing each plant for quality and rejecting all those which fall below the standards. This method is thus one of making sure of quality first and then looking for yield afterwards; theoretically, it is the method most likely to lead to success.

Between January and April this year some 8,000 single plants and lines were tested for quality at the College by the Pelshenke test, and it is safe to assume that a large majority of the single plants which have given a satisfactory Pelshenke figure will produce lines of satisfactory baking quality. Within two or three years the plant breeding plots at the College, which are now amongst the largest in Australia, will contain some thousands of crossbred lines of from fair to very good quality, and it is to be hoped that at least a few of these lines will possess yielding potentialities which will make them worthy of cultivation on a commercial scale.

The large majority of the populations of the two hundred odd crosses being grown at present are now in the second and third generation, and in this respect our work is as advanced as most in Australia, since it was not until 1932 that a determined move was made in any of the States towards the breeding of better quality wheats. Unfortunately, most of the crossbred material which was on hand before this time has been rejected on the score of poor baking quality, but some few lines, besides possessing desirable agronomic characters, have for two years in succession given satisfactory Pelshenke figures. These are now in advanced generations, and the time is ripe for submitting them to a baking test Indeed, after the current harvest there will be ample material ready for this test, and in subsequent harvests there should be hundreds of lines which will require testing.

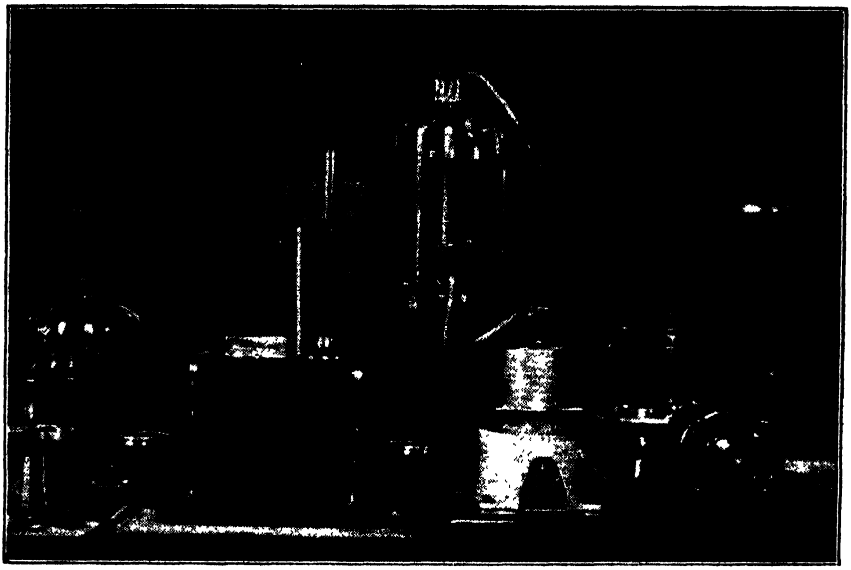
The need for handling large numbers of lines cannot be over-stressed. Experience in the past has shown that the combination of quality and yield is rare; consequently, the greater the number of lines studied the greater is the chance of isolating this desirable combination.

The College is fortunate in that it has as much typical wheat-growing land as is required for the work at its disposal, as well as a good supply of student labour, without which the expenses of the work would be very greatly increased. Given the indoor facilities in the way of modern apparatus, it will be in an unique position amongst the wheat-breeding stations in Australa, and the chances of producing the desired wheats will be greatly enhanced.

From the foregoing it will be seen that the programme of wheat improvement at Roseworthy College has already embodied the important principles of not allowing the good name of South Australia's wheat to be jeopardised in the future on the score of diminished quality. The objects are to check regression, to select and breed higher quality wheats, if possible, and in all cases to encourage and breed wheats which will be acceptable in quality, as in other characters, when treated as f.a.q. In this way no further retrogression should take place.

PROVISION OF THE NECESSARY EQUIPMENT.

While the Pelshenke test is both indispensable and satisfactory for early selective work, more critical tests are required when selected lines are in advanced generations. The gluten washing test is a handy supplement to the Pelshenke test, and the necessary equipment for the former was recently donated to the College by the Millers' Produce Company of South Australia Limited. The Rotor Gluten Washing Apparatus, generously presented, has already been of very great assistance. At present work on the standardisation of the test for our own requirements is being carried out, and in the future as many selected wheat lines as possible will be studied by this method.



Photograph of the Gluten Washing Apparatus presented to the College by the Millers Produce Coy. of South Australia Ltd.

The above actually defines the whole of the equipment at present in use at the College. It has been ample for the preliminary work of the improvement programme, and has accordingly sufficed to date. As the work advances, however, adequate equipment is essential to mill new strains of wheat, and to bake in an experimental way in order to test the merits or demerits of selected strains. Within the next year more substantial and conclusive tests will be necessary, involving baking tests. Sufficient grain of a number of new lines will be available after this harvest for such. This in itself is an admission that the baking of commercial loaves of bread from those new wheats gives the ultimate criterion of quality.

The equipment necessary to enable this to be done is costly, and, on being approached, the Millers' Produce Company of South Australia Limited, because of their interest and, it is felt, appreciation of the work being done at the College, have generously offered £100 towards this, and it is confidently anticipated that the Government will provide the remainder of the money required. Fundamentally, the sole aim is to do work of a practical nature to carry the plant breeding programme through to its logical end. In no way is it intended to seek elaborate equipment for cereal chemistry research; the latter presents problems the solution of which is the function of purely research institutions and organisations.

Negotiations are now in hand for the purchase of a small mill, proofing cabinet, and baking oven, together with supplementary apparatus, so that the College will be in a position to proceed independently with its work.

Baking tests permit only a few samples being done daily, so that only those lines which have proven agronomic characters, and which have given satisfactory Pelshenke and gluten figures, will be milled for baking. It is certain that, with the installation of the apparatus referred to, the College will be able to safeguard its policy of liberating for cultivation only those wheats which will be acceptable to the baker, and reflect credit on South Australian wheat generally.

To the Millers' Produce Company of South Australia Limited the College is deeply grateful, and appreciates the interest and generosity shown.

INCIDENTAL STUDIES.

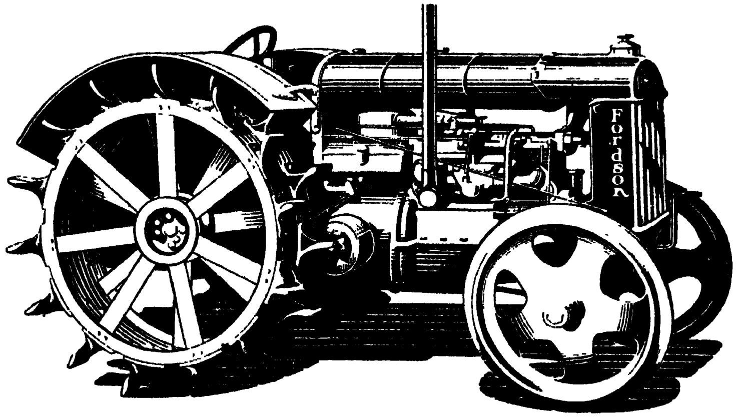
a. Genetical.—Without losing sight of the economic aspect of the work, studies are being made on the inheritance of baking quality. The comprehension of the mode of inheritance of any particular character is of great importance to the plant breeder, but so far very little has been done, anywhere in the world, which will throw light on the mode of inheritance of baking quality. The method adopted at the College for the breeding of high quality wheats provides excellent material for such a study; observations to date have given some very interesting information.

Results indicate that the mode of inheritance is governed by the high quality parent used in the cross. In all crosses between Dundee and low quality wheats, only about 15 per cent. of the single plants from the second generation population gave a figure of 50 minutes or more while in crosses containing Pusa 4, 70 per cent. of the plants exceeded 50 minutes. Admittedly, the Pelshenke figure for Pusa 4 is higher than that for Dundee, but even so, the proportion of plants which gave a figure superior to the intermediate figure between those of the two parents was higher in all Pusa 4 crosses. This indicates, of course, that the possibility of recovering the parental quality is much greater in Pusa 4 than in Dundee crosses.

In certain crosses between two low quality wheats it was found that it is not unreasonable to expect the evolution of lines possessing at least moderate baking quality. Quite a large number of plants were discovered in such crosses, and notably in those containing Sword, which gave a figure much higher than the expectancy.

Work on the subject revealed that the kernel texture, in some crosses at least, is such a poor guide to baking quality that its use is not warranted. A large number of samples of grain which were hard and flinty gave a disappointingly low figure. Conversely, a number which were relatively soft and starchy gave a very satisfactory figure. This former phenomenon was most noticeable in the F3 lines of the cross Cadia x Sword. Cadia is a high quality wheat, with a hard vitreous kernel, and Sword possesses only fair quality and is soft kernelled.

SAVE TIME and MONEY IN PLOUGHING . . .
with a FORDSON



14 H.P. AT DRAWBAR — 26 H.P. ON BELT
(Tests by Mr. E. J. C. Rennie, Melb. University)

FORDSON IS POUNDS UNDER THE PRICE OF ANY OTHER TRACTOR OF EQUIVALENT POWER

COUNTER-BALANCED CRANKSHAFT . . . . HEAVY-DUTY TRANSMISSION . . . GOVERNOR CONTROL . . . SPECIAL AIR CLEANING SYSTEM . . . CRANKCASE VENTILATION . . . "HOT-SPOT" VAPORISER . . . CLUTCH PULLEY . . . POWER TAKE-OFF (optional at extra cost).

The English Fordson is the lowest-priced tractor per horse-power on the market. It saves time and money on every job—ploughing, harvesting, haulage or stationary work. Fordson is available with pneumatic tyres or approved wheel grips. Your local Ford dealer will explain the easy purchase terms provided by the special Fordson finance plan.

DUNLOP PRESTIGE IS BUILT ON PROGRESS

OBSOLETE .. SO DUNLOP HAS NO USE FOR IT!

~~WEFTED CORD CONSTRUCTION~~

~~In ordinary tyres, because of old methods of manufacture, casing cords are held in place by cross wefting. When the tyre is working this wefting rubs on the cords causing destructive internal friction which saps the life of the casing and wastes thousands of miles of tyre life.~~

WEFTLESS CORD —the modern casing construction

WEFTLESS Cord is an advance exclusive to Dunlop interests in Australia adopted because Dunlop scraps obsolete technique rather than deprive motorists of the world's most modern tyre improvements. WEFTLESS Cord eliminates the destructive internal heat caused by cross-wefting . . . the outcome—longer mileage and far greater safety.

Specify WEFTLESS CORD TYRES by DUNLOP for Better Service!

AS BRITISH AS THE FLAG

The following are details of a few of the lines tested:—

Line.	Appearance of Grain.	Pelshenke Figure.
G1.	Similar to Sword	48
G2.	Hard and vitreous, plump	37
G3.	Hard and vitreous, plump	95
G9.	Medium soft, plump	33
G19.	Very hard and vitreous, normal	94
G21.	Hard and vitreous, plump	32

It will be seen from these figures that there is no association between high Pelshenke figures and flintiness of grain.

The effect of seasonal variation upon Pelshenke figures is considerable and it is necessary for the plant breeder to test each line for at least two years in succession before he can be certain that the quality of the line is inherent and not caused merely by seasonal conditions. This applies particularly to crosses containing certain wheats which have an abnormal tendency to fluctuate from season to season. Nabawa and Aussie are examples. In the cross Nabawa x Canberra the 1933 harvest yielded F4 lines which gave very good Pelshenke figures, but from the 1934 harvest the corresponding F5 lines, without exception, fell below the desired standard.

Nabawa x Canberra Crossbred Lines.

Line.	Pelshenke Figure.	
	1933.	1934.
G4.	70	26
G5.	70	27
G6.	70	30
G9.	73	33
G10.	73	34
G17.	52	28
G18.	52	27

On the other hand, results over two years from certain crosses illustrate that seasonal variation does not influence the Pelshenke figure a great deal when quality is inherent:—

Ford x Carrabin Crossbred Lines.

G12.	74	70
G13.	74	74
G22.	93	66
G23.	93	77

The determination of the relative merits of the various high quality parents commonly used and the mode of inheritance of baking quality in typical crosses should be of value to all Australian plant breeders in that the most expedient and economical method of handling any particular cross may be calculated.

b. Environmental.—In order to choose parents for cross-breeding, it is essential to assess as near as possible the relative quality values of many varieties. Unfortunately, the inherent quality of a parent may, to some extent, be disguised by variations induced by environment. The leading fact remains that baking quality is definitely a heritable character in wheat; on the other hand, it is known that environment, as controlled by soil and climate, has a potent influence on quality. It is also common knowledge that some millers make a practice of buying from certain districts, while others show a preference to certain varieties. This likewise indicates the uncertainty of opinions in the matter. One necessary adjunct to the work being done at the College, therefore, is to assess, if possible, the range of variability in the quality of wheat grown in different districts.

With this end in view, the College began a quality survey of the wheat lands of the State last season. Farmers in all centres volunteered to help, and nearly 500 undertook to sow samples. Ford wheat was used as the variety, the seed of one strain grown under identical conditions at the College being distributed to the farmers, who were asked to sow a sample within one of their crops and return the produce to the College for study. In spite of the adverse seeding conditions and the ravages of grasshoppers, nearly 350 samples of grain were returned.

As all the samples are progeny of the same single line of Ford grown at the College the year before, variations in appearance and quality may thus be attributed to environment. The majority of the grain samples consist of well-filled grain, but superficial differences in appearance are quite remarkable, showing every gradation from hard, vitreous grain to soft, opaque, mealy grain.

To date the samples have only been subjected to the Pelshenke test, and the range is from 35 to 100 minutes. It would be premature to make any definite statements yet, as further tests, which are being conducted by the Chemist (Mr. A. R. Hickinbotham), are necessary, and a detailed report will be published separately. It will be necessary, of course, to repeat the survey over another two or three seasons before any worth-while conclusions can be formulated.

There are indications, however, that although district is a major factor in determining quality, there are other important factors operating. Varietal influence is very important, for the Ford samples, in the main, gave satisfactory Pelshenke figures. There is a rough association between the figures and the districts, but some surprisingly good samples have been obtained from districts which reputedly produce only low quality grain, and some poor samples were grown in the so-called "high quality" districts. It appears that time of planting and finishing conditions, to name only two factors, might have a larger influence upon quality than is generally realised.

It is difficult to forecast the ultimate value of this experiment, but it is anticipated that gluten and maltose tests will do much to elucidate the position, and determine the nature of the factors affecting quality and give an idea of the area of South Australian wheat country from which it is reasonable to expect the production of grain of good baking quality.

Such a survey must ultimately be a guide to the future developmental work of the College in the fostering of new varieties.

c. Cereal Chemistry Problems.—The baking quality of wheat constitutes its ability to satisfy commercial baking requirements; the cereal chemist is asked to explain the connection between a good loaf of bread and the flour from which it was made, ultimately, of course, going back to the grain from which the flour was milled. In the process of deciphering such relationships, many abstruse problems present themselves, simply because quality is the expression of many attributes of the grain itself.

The cereal chemist, by conducting other tests in conjunction with baking tests, can for the most part correlate defects or qualities of the commercial loaf with contributory causes in the grain. He has at his disposal tests which include gluten determinations, water absorption, viscosity, colour, and gassing power, as well as baking tests, all of which will help in the final and accurate assessment of quality. Many problems arise out of standardisation of methods, and there is considerable room for research work into such matters. This, however, as already stated, is a matter for purely research institutions and organisations; in point of fact, it is a Commonwealth concern. Facilities for research in the way of funds and staff absolutely preclude it from the itinerary of programmes where practical plant breeding is the main consideration. Research work of this kind is, however, fundamental to progress, and when standardised clear-cut methods are available, then undoubtedly they will be welcomed and earnestly accepted for use in the selection and isolation of better quality wheats. The solution of cereal chemistry problems is of national importance, involving, as it does, milling and baking interests. In point of fact, view the matter in full perspective, and the usefulness of such research to the plant breeder takes a very subsidiary and secondary position.

It is not the intention of the College, therefore, to embark on any research of this character, except minor details which may arise incidental to the routine work involved in the testing of new strains of wheat.

SUPERPHOSPHATE AND PERENNIAL RYE GRASS FOR PASTURES.

The South Australian Committee of the Australian Dairy Council has decided to encourage the use of superphosphate for pastures by purchasing a quantity of that fertiliser for distribution among dairymen. The maximum quantity to be supplied will be 2½cwts. per milking cow, and the fertiliser must be used as a top dressing.

Applicants must state:—

1. District in which the farm is situated.
2. Number of cows milked.
3. Top dressing applied per acre in 1934 and 1935.
4. Class of pasture it is proposed to top dress.
5. If assisted, whether prepared to subsidise dressing on a pound for pound basis.

Applications will also be received from dairymen who propose planting a perennial rye grass pasture this season and who desire a free supply of seed. Applicants must be milking at least seven cows and must state:—

1. The area of land to be planted.
2. Class of soil.
3. Previous history of field.
4. Tillage given.
5. Pasture mixture and manure to be seeded.

Those who avail themselves of this service are to supply progress reports and to allow the Department to inspect the pastures.

Applications for both superphosphate and Perennial Rye Grass will be received not later than 12th May by the Hon. Secretary, South Australian Committee of the Australian Dairy Council, Box 901E, G.P.O., Adelaide.

RAISING EXPORT LAMBS ON SUBTERRANEAN CLOVER PASTURE LANDS.

[By L. J. COOK, R.D.A. (Manager, Kybybolite Experimental Farm.)]

The experiment commenced in 1933, testing the raising of export fat lambs on Subterranean Clover pastures at the Kybybolite Experimental Farm, was continued again in 1935.

Five flocks were used similarly as in 1934, consisting of 44 Comeback ewes each, selected as evenly as possible according to age, development and live weight. All ewes were full mouthed, and weighed 115lbs. on the average at mating on 7th February, 1935.

The same breed sires, namely Southdown, Suffolk, Dorset Horn, Ryeland and English Leicester were mated, and grazing method was adopted, similar to that of the previous seasons, *i.e.*, whilst being mated the flocks were grazed in fields of approximately equal area, and containing similar pasturage. After mating, all ewes were run together as one flock, and grazed under a rotational system on good fertilised clover pastures.

A week before lambing commenced, the flock was again divided into its sections, and each run on similar type of clover pasture during the lambing period. After marking, lambs and ewes were again run together as one flock.

During the whole period, neither ewes nor lambs were handfed, and they existed and grew entirely on grazing.

All lambs were sold off their mothers, and in the wool, and were grazed only on Subterranean Clover with its mixture of naturalised grasses, such as Barley and Brome Grasses.

The flocks were examined twice daily during lambing, and note of births taken.

Assistance was given to six ewes, two of which were in lamb to the Southdown ram, and one each in lamb to the other sires, making the total number of 12 assisted during the three seasons' lambing period. Of these 12, 4 ewes were in lamb to Suffolk ram, 3 to Southdown, 2 to Dorset Horn, 2 to Ryeland, and 1 to English Leicester.

Four ewes died this season at lambing time, making a total of six ewes for the three seasons. Amongst these ewes 2 were in lamb to Ryeland ram, 2 to Suffolk, and 1 each to Dorset Horn and English Leicester.

Five ewes died whilst suckling their lambs, which included 2 with Ryeland lambs, 2 with Dorset Horn and 1 with Southdown lambs, at foot.

The ewes this year were affected somewhat by foot trouble, which occurred right at the lambing period, and caused, besides the loss amongst ewes, an unevenness of quality of lambs produced.

The following table shows the number of lambs born, died, marked and marketed from each of the flocks in all seasons.

TABLE I.—*Lambing Results.*

Season.	Ewes Mated.	Ewes Failed to Breed.	Ewes Died.	Total Lambs Born.		Lambs Born Dead.	Lambs Died between Birth and Marking.	Lambs Marked.			Lambs Died between Marking and Marketing.	Lambs Marketed.

Percentages quoted in above Table show per cent. of lambs to the number of ewes that bred.

The percentage of lambs marketed to number of ewes mated has been 91 per cent.

In the first column of Table I., it is to be noted that 24 ewes failed to breed this season, which is better than the previous season, when 45 ewes did not breed. This factor is probably due to the individuality of the ram used, only one ram being used in each flock. The English Leicester ram failed more than others this season, having 10 dry ewes in his flock out of the total of 24. There were 5 in the Ryeland flock; 4 in the Dorset Horn; 3 in the Suffolk; and 2 in the Southdown flock. For the three years, 23 failed to breed to the Southdown ram; 17 to English Leicester; 16 to Ryeland; and only 11 and 10 to the Dorset Horn and Suffolk respectively.

Column 2 shows that the loss of ewes before lambing has been very slight, only 4 from amongst 624 ewes in the three seasons.

Column 3 shows that the Dorset Horn cross with 56 lambs born, was the most prolific for this season, followed closely by the Ryeland cross with 52 and the Southdown cross with 50 lambs. The total lambs born—127 per cent. for the season—is the lowest for the three years, being 13 per cent. to 14 per cent. less than the previous two seasons, and reduces the average for the three year period to 135 per cent. For the full period, the Dorset Horn cross leads with 142 per cent. of births, the Ryeland cross is second with 137 per cent., and the Southdown cross lowest with 130 per cent.

Column 4 shows the number of lambs born dead, a total of 9 for this season which is below the average. The Dorset Horn cross with 4, and the Ryeland cross with 3, were the main losses at birth. The former has had 13 lambs born dead out of a total of 35 for the three seasons, showing that, although this cross has had the greatest number of births, it has been discounted by the larger number of lambs born dead, and those that died before marking.

Column 5 which shows the number of lamb deaths between birth and marking, discloses 15 deaths against the Dorset Horn cross out of a total of 46; 12 against the Ryeland cross; 9 against the English Leicester; and only 6 and 4 against the Suffolk and Southdown crosses. The total of 46 deaths was more than usual, and was no doubt due to the poorer condition of the ewes. The Suffolk and Southdown cross lambs—appear from this column—to have been the strongest on the average throughout the three seasons.

The next column reveals that the total percentage of 98.5 lambs marked from all crosses for 1935, is considerably less than usual, and has reduced the average to 111 per cent. for the three seasons. The Suffolk and Southdown crosses marked the most with approximately 105 per cent. each, although for the three seasons the Suffolk cross with 116 per cent. average is 5 per cent. better than the Dorset Horn, and Southdown crosses with 111½ per cent. and 111 per cent. respectively.

Only six lambs died between marking and marketing this season, which is less than usual. Of the six deaths, four were some of the best grown lambs of the Dorset Horn and Suffolk crosses, and were due apparently to "Enterotoxaemia."

The final column shows the number of each cross marketed each season, and the average percentage for the three seasons. This season 12 of the ewe lambs amongst the Comeback x English Leicester were not sold, but kept on the farm for special future work. Their live weights, however, were taken on the farm, and they were allowed average returns in compiling Tables Nos. 6 and 7 in this article. For the three seasons, 105 per cent. of lambs from ewes that bred were marketed, whilst 91 per cent. of lambs from ewes mated were marketed. The Southdown cross has marketed the greatest percentage with 108; Suffolk cross second with 106½ per cent.; English Leicester cross 104 per cent.; and the Ryeland and Dorset Horn crosses 102 per cent.

This season's lambs were marketed in two consignments, the first on 18th November (17 to 18 weeks of age), and the second on 10th December (20 to 21 weeks of age).

WEIGHT OF LAMBS.

Lambs were weighed individually on the farm before consignment, and the cold dressed weights have been provided by the Portland Freezing Works.

Table II. shows the average live and dressed weights of each cross in the six consignments forwarded during the past three seasons, with the percentages of dressed to live weight.

TABLE II.—*Weight of Lambs.*

	Average all Crosses—							
1933 ...	116 1st Consignment	534.............	73·5	73·5	30·5	30·6	41·4	41·6
	61 2nd Consignment		82·4		33·7		40·9	
1934 ...	101 1st Consignment		71·3		32·3		45·3	
	87 2nd Consignment		75·2		28·2		37·5	
1935 ...	120 1st Consignment		73·4		31·4		42·8	
	49 2nd Consignment		63·8		26·3		41·2	

The lambs did not develop as well as in the previous two seasons, and a fair proportion of the second consignment was light in weight. The first consignment averaged 73.4lbs. live weight and 31.4lbs. dressed, which shows a percentage dressed weight of 42.8 per cent., which is slightly better than the average of 41.6 per cent. for the three seasons. The second consignment averaged 63.8lbs. live, and 26.3lbs. dressed weight, a percentage dressed weight of 41.2, just a little less than the average.

Of the different crosses, practically little variation between the percentages of dressed to live weight occurred this season, between the Southdown, Suffolk and Dorset Horn crosses, but the Ryeland and English Leicester crosses were 1 to 1½ per cent. lower.

For the whole six consignments, the Southdown cross leads with 43 per cent. dressed to live weight, the Dorset Horn cross is second with 42.1 per cent., the Suffolk cross is third with 41.8 per cent., all three above the average of 41.6 per cent., whilst the Ryeland and English Leicester crosses were a little below average with 40.9 per cent. and 40.4 per cent. respectively. The whole 534 lambs averaged 73.5lbs. live weight when removed from their mothers, and dressed 30.6lbs. on the hooks; a very good weight for export purposes. The Dorset Horn cross produced the heaviest lambs; 76lbs. on the average and dressed 32lbs. The Suffolk and English Leicester crosses were 1lb. and 1½lbs. lighter in live weight, and dressed 31.3lbs. and 30.1lbs. respectively. The Southdown cross gave the lightest lambs, 69.3lbs. live weight, but dressed well with 29.8lbs. average. The Ryeland cross averaged 71.9lbs. live weight, and 29.4lbs. dressed.

QUALITY OF LAMBS.

Regarding the quality of the lambs for export, the following Table shows the number and percentages of carcasses of each cross in each consignment, placed in grades by the purchasers (Messrs. Borthwick Ltd.).

TABLE III.—*Quality of Lambs.*

	Total all crosses 534 lambs	325	60·9	184	34·5	20	3·7	5	0·9

This Table shows that of the 534 lambs, 325 were classed as first quality, 184 as second quality, 20 as third quality and 5 were rejected.

This result is satisfactory when it is remembered that every lamb reared in the flocks was sent to the freezers, except 5 lambs whose dams died shortly after birth, and 12 Comeback x English Leicester ewe lambs, that have been kept back on the farm this season for future breeding purposes.

The outstanding fact is the excellent quality of lambs produced by the Southdown cross; 92 lambs (81.4 per cent.) out of 113 of this cross were first quality, whereas the average of all crosses was only 60.9 per cent. first quality.

These Southdown cross lambs produced very fine, shapely carcasses of prime quality, comparatively even in weight. In live weight this season there was a variation of 26lbs. between the lightest and heaviest lambs, but 66 per cent. of the lambs weighed within 3lbs. of the average for all of the cross. The Comeback x Dorset Horn lambs ranked second in quality with 67.5 per cent. first quality, 30 per cent. second quality, and only 2.5 per cent. third quality. They were a fine, prime lot, growing and maturing quickly, but lacking in conformation. Also, there was a greater variation in the live weights, only 35 per cent. of the lambs this season weighing within 3lbs. of the average for the cross, and there was a difference of 33lbs. between the lightest and heaviest lambs.

The Comeback x Ryeland lambs produced 54.3 per cent. first quality, 37.1 per cent. second quality, and 8.6 per cent. third quality. The tops of this cross were very fine prime lambs, almost equal to the Southdown cross. The weights, however, varied more, and although like the Southdown cross there were only 25lbs. difference between the heaviest and lightest lamb, only 45 per cent. of the lambs weighed within 3lbs. of the average for the cross.

For shape and conformation the Comeback x English Leicester lambs were good, and were not greatly inferior to the Southdown. They were, however, slower in maturing, and did not thrive as well as other crosses; 52.8 per cent. of their carcasses were classed as first quality, and in evenness of weight and development they ranked next to the Southdown cross, 53 per cent. of their lambs weighing within 3lbs. of the average for the cross.

The Suffolk cross lambs continue to show to least advantage as regards quality. They were very strong, quick growing lambs, but lacking conformation. They also showed a lot of variation in development, 45 per cent. of these lambs weighed within 3lbs. of their average live weight, but there was a difference of 46lbs. between the lightest and heaviest lambs.

VALUE OF THE LAMBS.

The lambs were again sold on the hooks at Portland, and Table IV. gives the details of returns for the various crosses for this season.

Similar details for lambs sold in 1933 were published in volume 37, pages 1238-1240, South Australian *Journal of Agriculture,* and for those sold in 1934, in volume 39, page 42 of the same journal.

The prices in the final column indicate the net price per head for each cross received at Kybybolite, after paying freight and charges, and shows that the Comeback x Dorset Horn lambs returned the best price, namely 17s. 11¾d. per head, 1s. 1¼d. better than the Ryeland cross, which realised 16s. 10½d., and 1s. 1¾d. better than the Suffolk cross which realised 16s. 10d. each. The Southdown cross realised 16s. 2½d. each, and the English Leicester cross 15s. 11d.

The average price received for the whole of first consignment, which comprised the choicest of the lambs, was 17s. 6¾d. each, and that for the second consignment or later lambs was 14s. 11¾d., an average for the season's lambs of 16s. 9¾d. Amongst the first consignment, the Dorset Horn cross realised 18s. 1¼d. per head, the Southdown, and Suffolk crosses 17s. 5¾d., the Ryeland cross 17s. 4¼d., and the English Leicester cross 16s. 11½d.

The price received for lamb this season was 6 5/16th pence per lb. for first quality, which was 3/16th penny higher than price paid in 1934, whilst the price received for second quality lamb was 5 9/16th pence; ¼d. per lb. less than that paid in 1934.

The skin values were higher this season, and varied a little more than the previous year. The Ryeland cross averaged 3s. 11d. per skin, the Southdown cross 3s. 10d., English Leicester cross 3s. 9½d., Dorset Horn cross 3s. 8½d. and the Suffolk cross 3s. 8d.

The charges include 1s. 1d. freight from Kybybolite to Portland—an approximate distance of 150 miles—and selling commission.

In the next Table the prices received in 1933 and 1934 have been included with those of 1935, and the average price of each quality lamb has been computed for the three seasons.

TABLE V.—*Value of Lambs at Kybybolite*, 1933-35.

No.	Quality.	Breed.	Price per Lamb.			
			s.	*d.*	*s.*	*d.*
92	First	Comeback x Southdown	16	3¼	15	6¼
20	Second	Comeback x Southdown	13	8¼		
4	Rejects	Comeback x Southdown	7	10		
81	First	Comeback x Dorset Horn	17	6	16	3
36	Second	Comeback x Dorset Horn	13	10¼		
3	Third	Comeback x Dorset Horn	11	1½		
58	First	Comeback x Suffolk	17	1¼	15	4
59	Second	Comeback x Suffolk	14	5		
8	Third	Comeback x Suffolk	11	1		
2	Rejects	Comeback x Suffolk	8	5		
56	First	Comeback x English Leicester	17	0½	14	11¼
43	Second	Comeback x English Leciester	13	0		
3	Third	Comeback x English Leicester	9	10¼		
2	Rejects	Comeback x English Leicester	5	5¼		
38	First	Comeback x Ryeland	17	3¾	15	3
26	Second	Comeback x Ryeland	14	2¼		
6	Third	Comeback x Ryeland	9	6		
2	Rejects	Comeback x Ryeland	7	0¾		
		Average value of all lambs, 1933	15	1½		
		Average value of all lambs, 1934	14	10½		
		Average value of all lambs, 1935	16	9¾		
		Mean average value of all lambs, 1933-35	15	6		

These figures show that the whole of the lambs sent to the freezers realised 15s. 1½d. per head at Kybybolite in 1933, 14s. 10½d. in 1934, and 16s. 9¾d. in 1935, or a mean average of 15s. 6d. per head for the three seasons. The Dorset Horn cross has been the most valuable at 16s. 3d. per head, the Southdown cross has averaged 15s. 6¼d., the Suffolk cross 15s. 4d., Ryeland cross 15s. 3d., and the English Leicester cross 14s. 11¼d. These differences are appreciable, and show that the weighty Dorset Horn cross lambs—although they lacked in quality—realised approximately 9d. per head better than any other cross.

RETURN OF LAMB VALUE PER EWE THAT BRED.

The next Table compares the return per ewe from each flock, and to obviate the effect of single ram mating, the dry ewes have not been counted.

TABLE VI.—*Return of Lamb Value per Ewe that Bred.*

	Value per Ewe.	
	s.	*d.*
111 Comeback ewes mated to Southdown ram produced 120 marketed lambs..	16	8¼
123 Comeback ewes mated to Dorset Horn ram produced 125 marketed lambs..	16	6¼
124 Comeback ewes mated to Suffolk ram produced 131 marketed lambs	16	2½
117 Comeback ewes mated to English Leicester ram produced 120 marketed lambs	15	3¾
72 Comeback ewes mated to Ryeland ram produced 74 marketed lambs	15	8

This Table shows that the ewes mated to Southdown ram have returned 16s. 8¼d. each, 2d. more than the ewes mated to Dorset Horn ram, and 6d. more than those mated to the Suffolk ram, whilst those mated to Ryeland and English Leicester rams, have returned 15s. 8d. and 15s. 3¾d. each, or 1s. and 1s. 4½d. per ewe less than the Southdown cross.

These figures, however, do not take into account the question of early or late maturity of lambs, and as this varied with the different breeds, an allowance for grazing can be deducted, which would then give a better comparative value.

Table VII. shows deductions from the returns from each cross, allowing grazing of lambs at 2d. per week per head.

TABLE VII.—*Return Per Ewe Less Lamb Grazing Cost.*

Comeback x Southdown returned 16s. 8¼d per ewe
less 30 lambs for 12 weeks at 2s. 0d. each
less 17 lambs for 24 weeks at 4s. 0d. each
less 10 lambs for 13 weeks at 2s. 2d. each
less 19 lambs for 20 weeks at 3s. 4d. each
less 18 lambs for 16 weeks at 2s. 8d. each
less 26 lambs for 19 weeks at 3s. 2d. each
2s. 10¼d. equals 13s. 10d. per ewe.

Comeback x Dorset Horn returned 16s. 6¼d. per ewe
less 32 lambs for 12 weeks at 2s. 0d. each
less 13 lambs for 24 weeks at 4s. 0d. each
less 35 lambs for 13 weeks at 2s. 2d. each
less 11 lambs for 20 weeks at 3s. 4d. each
less 32 lambs for 16 weeks at 2s. 8d. each
less 2 lambs for 19 weeks at 3s. 2d. each
2s. 6¾d. equals 13s. 11½d. per ewe.

TABLE VII.—*Return Per Ewe Less Lamb Grazing Cost*—continued.

Comeback x Suffolk returned 16s. 2½d. per ewe.
less 35 lambs for 12 weeks at 2s. 0d. each
less 9 lambs for 24 weeks at 4s. 0d. each
less 28 lambs for 13 weeks at 2s. 2d. each
less 17 lambs for 20 weeks at 3s. 4d. each
less 34 lambs for 16 weeks at 2s. 8d. each
less 8 lambs for 19 weeks at 3s. 2d. each
2s. 7d. equals 13s. 7½d. per ewe.

Comeback x Leicester returned 15s. 3¾d. per ewe.
less 29 lambs for 12 weeks at 2s. 0d. each
less 22 lambs for 24 weeks at 4s. 0d. each
less 17 lambs for 13 weeks at 2s. 2d. each
less 21 lambs for 20 weeks at 3s. 4d. each
less 19 lambs for 16 weeks at 2s. 8d. each
less 12 lambs for 19 weeks at 3s. 2d. each
2s. 10¼d. equals 12s. 5½d. per ewe.

Comeback x Ryeland returned 15s. 8d. per ewe.
less 20 lambs for 13 weeks at 2s. 2d. each
less 19 lambs for 20 weeks at 3s. 4d. each
less 24 lambs for 16 weeks at 2s. 8d. each
less 11 lambs for 19 weeks at 3s. 2d. each
2s. 9¼d. equals 12s. 10¾d. per ewe.

With these allowances made, it is seen that the ewes mated to the Dorset Horn ram show an increase return of 1½d. per ewe above those mated to Southdown ram, and 4d. per ewe above those mated to Suffolk ram. Those mated to Ryeland and English Leicester rams have returned 1s. and 1s. 6d. per head less.

This report now shows the results of three seasons' work, and definitely proves that export fat lambs can be satisfactorily bred and developed on well fertilised Subterranean Clover pasture. It is also apparent that the Comeback ewe—which gives away very little in wool to the Merino—is quite a suitable dam for breeding these lambs. The results at present show that certain English Breed Sires are more productive than others, but it is necessary to repeat the trials for a few more seasons before arriving at a definite conclusion on the point.

The fields used for grazing the flocks in this experiment, contain principally Subterranean Clover and annual grasses such as Barley and Brome grasses. They receive 1cwt. 45 per cent. superphosphate annually, and this season have carried 4.42 sheep per acre under our modified system of rotational grazing.

THE NEED FOR DIVERSIFICATION IN FARMING THE LANDS OF THE BETTER RAINFALL AREAS IN SOUTH AUSTRALIA.

[R. HILL, Agricultural Instructor for Central District.]

As in all new countries, the early settlers in South Australia based the methods of farming on experience gained in their homeland, but the many differences due to climate, soil types, and access to markets for their produce forced adaptation to the altered conditions.

Their sound judgment in selecting the best land is evidenced by the localities chosen by the early landholders, but a century of experience has produced many changes in agricultural practices, which are still governed to some degree by the ability to market produce economically.

Science has played a big part in overcoming many difficulties in production and marketing, but the individual farmer still has many problems to face in obtaining maximum returns from his holding.

Various methods of working farms have been adopted, but definite changes have taken place in general agricultural practice.

Wheat crops for grain are no longer grown in any quantity on the Bald Hills at Mount Barker Springs where the Frame family once made history with such crops, nor are they grown in many other high rainfall districts where, under present conditions, the land can be utilised to greater advantage.

Later still, cereal crops for hay were replaced to a great extent by meadow hay, a change brought about principally by the untiring efforts of the late Mr. Howard, of Blakiston, in introducing Subterranean Clover seed commercially, followed by the practice of applying superphosphate to pasture lands.

Subterranean Clover and superphosphate have been the outstanding factors in pioneering a complete change in the farming practices in the heavy rainfall districts.

These two factors have, by raising the nitrogen level and improving the general physical condition of soils, made it possible to utilise land otherwise considered useless, and have paved the way for the introduction of a more diversified type of farming. What a change has taken place—even during the last decade—and how wonderful the possibilities of developing so much of the idle land in the high rainfall areas with the experience gained in recent years!

Potato crops are now being grown following Subterranean Clover on land very much despised only a few years ago, the establishing of better pastures, including their management, has improved, but there is still much to learn.

Those people interested in the development of pastures must realise that their work is not completed when Subterranean Clover pastures are established, and that, with the raising of the nitrogen level of soils, other permanent pasture plants must be introduced, coupled with the subdivision of holdings into small fields in order to afford facilities for satisfactory management.

As in the low rainfall districts, the high rainfall areas have a lean period which must be provided for by the conservation of fodders consisting of hay and ensilage in spring and the growing of fodder crops principally during summer.

All these things are possible, and surely the changed conditions provide an opportunity, and what is more, the necessity for diversification in farming practices on land already developed, and large areas still in a virgin state.

Throughout the area in question, the carrying capacity of land has been considerably increased, and there is a tendency to reduce the area of the larger holdings in order to develop a more intense type of farming. This is a sign of progress which presents an opportunity for closer settlement, increased population, and more economic production.

Although rarely seen on small holdings a few years ago, sheep are proving themselves to be important revenue-earners to-day, and the fat lamb industry has been consolidated because of their presence in the sure rainfall districts.

Where only dairy cows and pigs were carried on holdings a few years ago, to-day beef cattle and sheep are recognised as necessary additions to the livestock population where maximum returns and economic grazing of improved pastures are considered. Permanent pastures need renewing from time to time when cultivated crops, including potatoes, may be grown to advantage and the fields improved in condition for new pastures which are to follow.

In this, the centenary year of the State, thoughts are more than ever diverted to the pioneers of many years ago, who blazed the trail in establishing agriculture in South Australia. They arrived in a new country, some with previous agricultural experience, but all had much to learn in the new environment. Undoubtedly many mistakes were made, but their wisdom in recognising the potential value of lands in assured rainfall districts was a gift of foresight, unfortunately not inherited by later generations.

SOUTH AUSTRALIAN COMMITTEE OF AUSTRALIAN DAIRY COUNCIL—DAIRY FARM COMPETITION, 1935.

CONSERVATION OF FODDER SECTION.—HILLS DISTRICT AND MURRAY SWAMPS.

[Judged by R. Hill, District Agricultural Instructor.]

Meadow Hay and Ensilage Competitions conducted in recent years have now been combined and other fodder crops added in order to provide a Competition for Conserved Fodders. This Competition, combined with those for Pastures and the best Dairy Herd, provide a general Dairy Farm Competition with a prize for the aggregate.

The Conservation of Fodder Competition has been judged on the following scale of points:—

	Points.
Hay	60
Ensilage	60
Amount conserved per cow	60
Other crops	20
Total	200

It is unfortunate that a number of the competitors were not represented in all sections, and in some cases only Meadow Hay was entered. However, the Competition has provided data showing to what extent conserved fodders can be utilised and the feed question made secure.

The carrying capacity of holdings, so far as the Hills Districts are concerned, has been decidedly advanced with the curing of Meadow Hay being better understood than was the case a few years ago and the making of Ensilage having progressed past the experimental stage.

It was pleasing to notice on some farms visited that the Pastures were well grazed down, preventing unnecessary waste, and every opportunity had been taken to utilize the strong, spring growth as Conserved Fodder either as Hay or Ensilage. Approximately 3 tons of conserved fodder per cow were stored on several of the farms visited, and in one case it was as high as 5½ tons, showing what can be done, and providing an excellent object lesson to any interested in improving the carrying capacity of their holdings. From a dairyman's point of view, both Ensilage and Hay are essential, and neither should be used as a sole ration. Ensilage has decided laxative qualities, and in addition helps digestion—both very important factors when considering economical feeding for dairy cows, and all dairymen should give that type of conserved fodder more consideration.

Although the practice of using salt in Haystacks is becoming more general, much more consideration should be given to its use, both as a protection against firing and its assistance in promoting a more palatable feed.

Cultivated crops for grazing purposes in the Hills Districts do not attract a great deal of attention, because of the area and number of fields necessary to carry on such work successfully, but such crops grown for cutting and hand-feeding might be given more consideration.

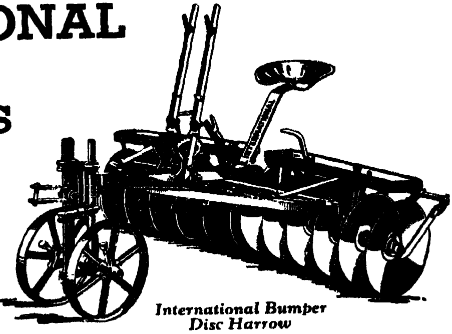
HARROWS

. . . for every kind and condition of soil

● Generations of capable farmers have tested and proved the quality of International harrows which are made from a close knowledge of practical farming requirements.

INTERNATIONAL BUMPER DISC HARROWS

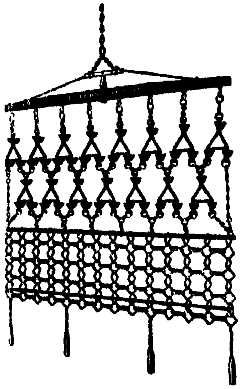
● One of the most popular and useful tillage implements made, the International bumper disc harrow is sturdy in structure and simple in design. Made in 5, 6, 7 and 8-ft. sizes with 16-inch discs and 6, 7 and 8-ft. sizes with 20-inch discs. Tandem attachment available.



International Bumper Disc Harrow

INTERNATIONAL PASTURE HARROWS

● Made entirely of steel the International pasture harrow is simple in construction, sturdy, flexible, light in draught. Breaks up sod-bound land and opens up the soil so that fertilizer can be worked into the roots. Also breaks up and distributes animal manure evenly over the pasture. Works effectively in tussocks or in heavy dry grass. Made in 5, 8, 10 and 15-ft. sizes.



International Pasture Harrow

INTERNATIONAL DIAMOND Smoothing Harrows

● This is a light, serviceable steel harrow which conforms to the surface of the ground. Frame made of channel and flat steel bars and the teeth of high quality steel with threaded heads inserted through the frame bars. Made in 20-tooth sections 40 inches wide. Supplied with as many sections as required.

THE GROWING OF CANARY SEED (*PHALARIS CANARIENSIS*) IN SOUTH AUSTRALIA.

[By R. HILL, District Agricultural Instructor.]

For many years odd crops of canary seed have been grown in this State, and it seems possible to grow reasonably good yields and fair quality seed in most of the cereal growing districts favoured with a rainfall from 17in. and over per annum, but during the last few years the area sown to this crop has increased considerably.

The total quantity of seed harvested this season will be in the vicinity of 850 tons, and the amount of seed required for birds locally will, at the most, be 450 tons.

However, the price is good and local growers have benefited, but this position cannot be expected to continue, and any prospective growers should give the matter full consideration before making a decision.

The total annual requirements throughout Australia are in the vicinity of 2,500 tons, and of this Queensland has been the main supplier, but a poor season for the crop in that State, coupled with the fact that Victoria will have only about 100 tons, or 25 per cent. of her expected crop, has placed South Australian growers in a very favourable position.

Should the area under crop continue to increase and only a moderate season be experienced in all States, prices are sure to fall, with the only possible outlet of exporting at a price not remunerative to the grower.

South Australian growers have formed an association which entrusts its business to Messrs. Whiting and Chambers, and both Queensland and Victoria have their respective associations of growers. These three bodies have formed an Australian association, hoping that the area cropped and the general quality of seed marketed will come under some definite control.

Whilst prices have been good, there has been a tendency in this State to overlook the important item of quality, and until more attention is directed to careful harvesting, there is little hope of building up a high standard of quality that is so much desired.

All plants of the *Phalaris* family have the peculiarity of ripening the seeds at the apex of the head earlier than the remainder, and those seeds show an inclination to shake out before the lower seeds are fully matured.

Such a condition presents difficulties at harvest time unless the crop is cut with a binder at a stage when the earlier ripened seed will not shake out. Allowed to complete ripening in the stook, the seed will be more uniform and can be threshed through an ordinary threshing machine without undue harm to the seed. Such a method of harvesting involves more labour, which is to some degree overcome by additional yield and less damage to seed.

Skinned seed is not appreciated by birds, and any degree of skinning considerably reduces its value, due to the waste when fed to them, a fact which must be realized by growers if a market for their produce is to be held.

As indicated by the figures quoted, there is a limited demand for canary seed in Australia, and unless the industry is controlled and the production of good quality seed left to growers who are in the position to handle the crop with suitable equipment, there is likely to be a decided slump in prices which might possibly discourage growers to the extent of disorganising the local supply and giving the industry a decided check.

ASSISTING LANDHOLDERS IN CLEARING OPERATIONS.

[A. C. H. RICHARDSON, Chairman Unemployment Relief Council.]

For the twofold purpose of placing men in employment and assisting primary producers to undertake work to bring more land under cultivation which, through lack of finance they would otherwise be unable to do, the Unemployment Relief Council has undertaken a scheme of clearing land for farmers.

The farmer who desires to take advantage of this scheme is required to state the area which he desires cleared and give a general description of the type of growth on the land in question. He is also asked to state the rate per acre which he is prepared to pay.

In the event of the Council granting assistance it is essential that there must be reasonable security available for the repayment of the advance made. The farmer should, therefore, give particulars of his title to the land, whether it is freehold or leasehold, and if encumbered, details of the encumbrance should be supplied. The repayments will be spread over a reasonably long term. Nothing is definitely fixed in this direction, but if the farmer indicates the period over which he desires repayment spread, this can be considered and mutually fixed. The rate of interest charged for the advance is reasonable, being only 4½ per cent.

After an arrangement is entered into between the Council and any landholder it will be necessary to have a suitable camping site in close proximity to the clearing operations. An ample water supply for drinking and washing purposes is essential, and such factors as accessibility for conveyances and suitable arrangements being made for stores and provisions will be considered in the selection of the site. All campng equipment, tools, &c., will be supplied by the Council, and the men sent to the job will be required to work under the Petty Contract System. In this respect the matter is one enirely between the landowner and the workmen—the Unemployment Relief Council finds the labour and provides the finance only. Each fortnight the area cleared can be measured by the farmer so that the men can receive their payment in accordance with the services rendered.

Work has been undertaken under similar conditions by the Council previously, and apart from huge areas which have been cleared for forestry purposes, the Council has done several clearing jobs for farmers, but it is felt that the scheme and the method of its working are not generally known by those who have land which they require cleared. At Coonalpyn 1,008 acres were cleared and grubbed for Mr. W. B. Watson, and he found the scheme quite satisfactory and was pleased with what was achieved.

The Council feels that many acres on various holdings have not been reclaimed from natural forest because of lack of finance and the difficulty of over-burdening the property to such an extent as would make farming unproductive. In devising this scheme the Council asks for only reasonable security, and it will be generally agreed that where it is dealing with public funds this course is necessary, quite apart from being a general practice of business. It has spread the period of repayment over a long period and has set the interest at a reasonable rate.

In inaugurating this scheme the Council feels that in its efforts to relieve unemployment, it could not do better than turn to the primary producers of the State, for it believes that any help rendered in this direction, which will be of genuine help to the farmer, is likely to have a lasting effect on the community as a whole.

PAPERS READ AT CONFERENCES.

PEAS ON THE FARM.

[W. F. WURST, Laura.]

The Early Brunswick White is the best variety of pea for northern conditions. The Early Dun is about two weeks later; it grows a lot of bulk, but not so much grain, and, being late, it is far more subject to the attack of grubs. The Brunswick is a hardy pea, being early and of good feeding quality. Not growing so much bulk, it is much easier to harvest with present-day machines. In a district with a fair rainfall, it will grow quite well on stubble ground. The stubble should be burnt or cleared off; then, after the first rain, either ploughed or cultivated about April or May, well cleared of all stones, &c., and sown with about 60lbs. to 80lbs. of seed and a liberal dressing of manure at about the end of June. If the peas are sown too early they are likely to be caught by frost. If sown too late they are subject to the ravages of grubs.

Be careful to kill weeds as far as possible. After seeding, roll the soil down well, as that will save a lot of trouble, time, and waste at harvesting. If the soil is well rolled the peas may be cut with the binder just before they are ripe, especially if there are some wild oats, &c., in the crop. This can be thrashed later, the straw making an excellent standby for idle stock in winter months. Sheep will do well on pea stubble with a liberal supply of water. They will fatten more quickly than on any other feed, giving a good, solid, juicy mutton. The sheep will pick up practically every grain. Farmers cannot expect soils to keep in the best producing condition with a continual wheat-fallow-wheat rotation, and there is nothing better than a change with peas. To keep the soil fertile a good plan is to give it a rotation of wheat (or oats), peas, fallow, wheat, peas, fallow. This will give two crops in three years, and will enrich the soil. It is a far better policy to sow smaller areas and have a good crop than a big area with a poor return.

Two years ago I started by sowing 60 acres, last year 250 acres, and it is my intention to sow 350 acres this seeding with peas.

THE GROWTH OF BEETALOO VALLEY.

[J. ARTHUR, Beetaloo Valley.]

Formerly, what is now Beetaloo Valley was partly Napperby and partly Beetaloo Stations, held as pastoral leases. Through the influence of Mr. Howe, then a Member of Parliament, a closer settlement scheme was instituted. Blocks of land were selected, varying in size from 20 to 100 acres. This scheme—which ultimately proved a failure—partially, at any rate, meant the opening up of what is now a wonderfully fertile belt of both agricultural and horticultural land. The early settlers had a colossal task ahead in clearing land which was hilly, heavily timbered, and containing stone reefs. Mixed farming was the idea of this closer settlement scheme, and gardening was to be the main feature. The hills in Beetaloo Valley became dotted with vineyards and orchards, comprising citrus and stone fruits, but, through lack of organisation, they found only a limited market for what they could produce; also these small areas proved far too small; so one by one allotments were forfeited, to be re-allotted—in some cases sold to more prosperous neighbours—until to-day Beetaloo is carrying prosperous farmers, with holdings from 500 to 1,000 acres, with a few smaller properties devoted to gardening.

It is true that during the last decade the annual rainfall has dropped to the extent of nearly 10in. As a result, stone fruit orchards and vines have gone almost out of existence, leaving mainly citrus fruits, which are sustained by a system of irrigation from the Beetaloo Reservoir. One of the chief drawbacks to the early settlers of Beetaloo was the fact that little was known of the value of superphosphate. It is feasible to assume that had artificial manures been scientifically prepared 50 years ago as they are to-day, mixed farming would be the order of the day in Beetaloo Valley on holdings up to 200 acres, unless, of course, the fall in the annual rainfall proves to be permanent. With a 29in. rainfall, which was the case a decade ago, and which will surely return, and with the present-day knowledge of the value of artificial manures, two to four families could live where one exists to-day by utilising to its fullest capacity a holding of 200 acres. The fruit-growing industry has never been organised in Beetaloo. This could, and would be done if sufficient fruit was grown to warrant it; but it will never be done while holdings range from 500 to 1,000 acres.

The decrease in annual rainfall, although a drawback to the gardener, has been a boon to the wheatgrower. It enables him to cope more easily with weeds, which prove a pest in wet winters, and it is safe to say that the average yield per acre during the drier seasons has been greater than previously. During nine years' residence in Beetaloo I have never seen a bad crop of wheat. I know of no farmer in Beetaloo who could not cut from 30cwts. to 2 tons of hay per acre, and wheat yields are invariably from 20bush. to 30bush. per acre.

LOWER SOUTH-EAST, KYBYBOLITE, 8th APRIL, 1936.

WIMMERA RYE AND *PHALARIS TUBEROSA* ON RED GUM LANDS OF THE SOUTH-EAST.

[By L. J. Cook, Manager Kybybolite Experimental Farm.]

It is most necessary to consider the grass varieties that are suitable to the South-East and its climate, because they are essential for use and maintenance of pasture, now fully recognised as our most stable crop.

Subterranean and other clovers are invaluable pasture plants, but they cannot and will not make a persistent pasture. It is only by a combination of grass and clover with good fertilising and proper management that continuously healthy and productive pastures can be maintained. Clovers make quick use of phosphatic fertiliser, and are able to secure their nitrogen requirement from the air per the medium of root bacteria, which at the same time supply an excess of nitrogen that combines with the chemical bases of the soil for use by other plants such as grasses.

Grasses also make use of phosphatic fertiliser, but in addition they require readily available nitrogen in the soil for their proper growth.

Consequently soils—such as most of those in the South-East—that are naturally very low in phosphates and nitrogen respond to the following treatment:—Phosphatic fertiliser applied to a clover pasture cause—during the first two to four seasons—a dominance of clover growth, as much as 80 per cent. to 90 per cent. of the total growths at times. This period is followed by better grass and a reduction of clover, brought about by the added nitrogen made available in the soil by the clover growths, and after a period of 8 to 10 years' development grass produces 60 per cent. to 70 per cent. of the pasture growths. These latter pastures are of greater utility to livestock, providing a variety and better balance of food.

For quite a number of years grass growths have been under observation, and trials conducted with introduced species, in order to obtain the most suitable and productive for the soil and climate. Many of these trials have been made on undeveloped land, and of later years trials have been set on the more or less partly-developed soils. Much is still to be done, testing under different methods of management, fertilisation, &c., but the purpose of this paper is to deal principally with the results so far obtained. Conclusions arrived at under practical trials indicate that only two of the introduced grasses are outstanding and are to be recommended, namely, Wimmera or Annual Rye Grass and *Phalaris tuberosa* (Perennial Canary Grass). These two are of quite different type. Wimmera Rye is an annual, growing from seed each autumn, producing dark green, narrow-bladed leaves, makes quite good winter feed and a luscious amount of spring growth. *Phalaris tuberosa*, on the other hand, is a deep-rooted perennial, is very drought-resistant, and can live through dry summer periods. It produces light green, fairly broad-bladed leaves, and makes a fairly quick bite of green from autumn rains, is a good winter grower, and makes growth later into the summer than any other winter grass tried. Hence these two grasses require quite different treatment and management.

WIMMERA RYE GRASS.

Wimmera Rye is a prolific seeder of very viable seed, and it is not difficult to secure a good germination provided a reasonable seedbed is given. Sown in autumn it can be grazed well during its first winter until spring, when it is most essential that it be allowed to mature a good proportion of seed. Heavy grazing in late spring is very detrimental to its persistency, as livestock are particularly fond of its palatable seed heads. If allowed to seed well the first season it is not so necessary to control the spring grazing during future seasons, except that it might be advisable every third or fourth season to allow it a fair spell to mature seed. Autumn harrowing will aid its growth and persistency. Spring mowing for ensilage and hay will materially aid it, provided the mowing is not left too late in the season. Cut off early, naturalised annuals such as Silver, Barley, and Brome grasses can be checked to the advantage of Wimmera Rye. Wimmera Rye Grass in pastures properly managed noticeably reduces the amount of other annuals such as Cape Weed and the grasses mentioned above. It can, with advantage, be established with Subterranean Clover in the initial stages of development of these lands, and although, of course, it makes far better and more healthy growth in later stages of development, it does better than other grasses in the early stage, and is most useful for livestock at this period.

PHALARIS TUBEROSA.

Phalaris tuberosa is not a prolific seeder under local conditions, and there is a large variation in the viability of its seed. The cost of the seed is much greater than that of Rye Grass, and it is more difficult to obtain a good germination. It is a slow grower during the first six months of its life, and consequently does not appreciate competition at this period. Therefore, to establish, it is necessary to prepare and clean the land very well. Sown in autumn, it will give very little feed during the first winter, but will make useful growth in spring and early summer. During the second and future seasons it will hold its own and persist for a good many years under proper management. It is advisable to use the mower freely in spring during early seasons of its development to check annual grasses. When its plants become larger and well established it will better defeat the annuals, but during the early years it is noticeable that annuals are more plentiful amongst it than in the Wimmera Rye Grass plots. Autumn harrowing should be an advantage.

Except for the first year of growth, the grazing of *Phalaris* need not be interfered with, provided that the grazing is so managed to enable the maintenance of healthy plants. Rotational grazing should be observed during the growing period in order to allow sufficient top growth to maintain vigorous root development and prevent over-grazing of such a very palatable species as *Phalaris*.

Unlike Wimmera Rye Grass, *Phalaris* cannot be so well recommended for sowing on virgin land. It will not produce the quantity of grass amongst the

"Anyone lost a

clover during the first two seasons, and results in the production of a lot of weak plants.

It is the only persistent perennial that can be recommended for establishing on the land, after the soil has been built up with clover and phosphates for a period of years.

PRACTICAL RESULTS AT KYBYBOLITE.

Regarding practicable comparable trials of the two grasses, work with *Phalaris tuberosa* was commenced in 1930. Previous to this, small hand plot trials had shown the persistency of the grass, but it was not until 1930 that an area of 5 acres was established to commence a test of its grazing capabilities. This was established on virgin land, and six years' grazing in conjunction with Subterranean Clover has yielded 3.14 sheep per acre per annum, besides a cut of 21cwts. of hay per acre in 1934. During 1935 it has carried 4.1 sheep per acre.

A similar plot established with Wimmera Rye Grass at about the same time has returned 2.88 sheep per acre per annum, as well as a cut of 21cwts. of hay per acre in 1934. During 1935 this plot carried 4.4 sheep per acre. In 1934 a more comprehensive test of the two was commenced, and three more pairs of plots were established that year—one pair on virgin land, one pair after four years of clover development, and one pair after 10 years of clover development. Besides using these as a test on the quantity of grazing, the Waite Research Institute is assisting in the anlyses of growths and in the testing of the development of sheep on each type of pasture. The wool experts of the School of Mines, Mr. Codrington and his assistant Mr. Goddard, are also assisting with the selection of sheep and the valuing of the wool produced. This sheep work was commenced in 1935, and will be continued for five seasons.

More work must be recorded before any definite comparison of the grazing capacity of the two grasses can be quoted. All plots have been well covered with sown grass, naturalised grasses, clovers, &c., and so far there has been no material difference between their bulk of grazing.

Botanical estimations of these pastures have been made by the Farm Assistant, Mr. J. D. McAuliffe, by taking indiscriminate quadrat readings monthly throughout 1935 on the eight plots, and the following table shows the average botanical analysis for this season, and illustrates several important factors: –

Botanical Analyses of Wimmera Rye and Phalaris Tuberosa *Plots*, 1935.

4 *Phalaris* plots	21·94	—	25·03	46·13	1·61	0·57	—	1·12	3·60

Dev. = Development.

The principal factor shown is the reduction of naturalised annual grasses on the Wimmera Rye Grass plots. In every pair of plots the percentage of these is much higher (over 100 per cent.) on the *Phalaris tuberosa* plots. On the four Rye Grass plots the percentage of these annual grasses is 11.8, whilst on the four *Phalaris* plots it is 25 per cent.

Secondly, the percentage of Rye Grass to *Phalaris* on each pair of plots is greater; on the average 42.9 per cent. to 21.9 per cent.—almost 100 per cent. better. The total grass on the Wimmera Rye pastures is approximately 55 per cent., 43 per cent. Wimmera Rye, and 12 per cent. other annual grasses, whereas the total grass on the *Phalaris tuberosa* pastures is approximately 47 per cent., 22 per cent. *Phalaris* and 25 per cent. annual grasses. Thistles, Capeweed, and miscellaneous plants are present in greater quantity on the *Phalaris* pastures.

Considering the three *Phalaris* pastures established in 1934, it is significant that this grass is represented by 35 per cent. of the pasture when sown after 10 years' improvement, 27 per cent. when sown after four years' development, and only 13 per cent. when sown on virgin land.

Wimmera Rye Grass under similar treatment has produced 59 per cent., 57 per cent., and 34 per cent. respectively.

Comparing the pair of plots P3A and P4A, established on virgin land in 1934, it is found that Wimmera Rye comprises 34 per cent. of the pasture on its plot, whereas *Phalaris tuberosa* comprises only 13 per cent. of the pasture on its plot.

Plots P14 and P17 that were sown in 1930 are interesting, and show Wimmera Rye in much greater proportion than *Phalaris*. The comparatively low amount of grass and high amount of clover on both these plots, is due to the fact that they were mown for hay in 1934. In fairness to P17 it must be stated that the *Phalaris* was established here with only 2lbs. seed per acre. The later plots were sown with 4lbs. seed, and it will be interesting in future years to compare the development of *Phalaris* plants on C2 and P15 with those on P3A. Much larger and more vigorous plants are at present on C2 and P15, due to the previous developmental treatment given to these soils, and it can be quite anticipated that they will continue to develop better and maintain a better percentage than is at present showing on P17.

SHEEP ON WIMMERA RYE AND PHALARIS TUBEROSA PASTURES.

Regarding the development of sheep on these two types of pasture, 40 ewe weaners were selected of even type and development, of an average live weight of 58lbs., and were placed on each pasture in April last. Both flocks reached their maximum live weight for the season in January of this year; those on Wimmera Rye pasture weighing 101.3lbs. average, and those on *Phalaris* pasture 100.2lbs. In February the former had fallen to 94lbs. and the latter to 92lbs. average.

Those on the Wimmera Rye have been slightly ahead all the season, and produced 9lbs. 3ozs. of wool valued in October at 10s. 9¼d. per head, whilst those on *Phalaris* pasture produced 8lbs. of wool valued at 9s. 8¼d. per head.

The fleece wool of both flocks only varied 2½d. per head, that of the weaners on Wimmera Rye Grass averaged 15d. per lb. and that of the weaners on *Phalaris tuberosa* averaged 15¼d. per lb.

Of the 40 fleeces taken from weaners on Wimmera Rye pasture, one was valued over 17d., eight over 16d. and under 17d., and four were valued below 14d. Of the 40 fleeces taken from weaners grazed on *Phalaris* pasture, one also was valued over 17d., 13 over 16d. and under 17d., but none were valued below 14d. per lb.

Not much notice of these sheep results should be taken, for as yet they are only one season's result, but they will be used as a basis for comparing the clips from these sheep in future seasons.

[*Papers Read at Conferences.*]

SUMMARY.

1. Recommend that Wimmera Rye Grass be used with Subterranean Clover for the initial development of these lands.

2. *Phalaris tuberosa* with Subterranean Clover and naturalised grasses will produce equal carrying capacity as Wimmera Rye and Subterranean Clover, but it is advisable to delay its establishment until the land has been partly developed.

UPPER SOUTH-EASTERN BRANCHES, BORDERTOWN,

1st APRIL, 1936.

GENERAL FEEDING OF STOCK.

[A. E. MILNE, Tatiara.]

HORSES.

A foal should be weaned from the mother at five to six months old. If possible, have the foal in a strong yard with stable or loose box attached. Have water laid on and a trough, so the foal can get it any time it likes. Do not feed too heavy; make the feed green chaff and plenty of bran and a good allowance of crushed oats. If the foal does not eat all the feed, clean it up and give less. In spring, do not feed too much chaff, provided there is plenty of natural feed. At this stage the colt should develop, but not get too fat.

From now on, give as much as the colt will eat, but if possible the best of food. At two and a half to three years, the colt is ready to handle. As the colt works be liberal with the feed—four times a day. Do not make the midday feed too bulky, but good.

The master must use his own judgment. Some horses will eat much more than others. Do not give more than they will clean up. The stomach of a horse is small, and the animal cannot do his best if he is too full. Oats are the best feed at any time the horse is at work, and should be crushed to help digestion. If not crushed, steep in hot water. If the tin is covered with a bag it will give good results. Allow the horses plenty of water before feeding, and very little, if any, after. Too much water helps to dispose of the food before it has been digested.

To sum up. Feed the best chaff made from hay cut on the green side together with oats and bran, mixing a little salt. Put salts in the drinking water. Do not tip a bran bag of chaff to two or three horses.

COWS.

At all times, dairy cows will respond to green feed in any shape or form. Therefore, grow barley or rye for early feed, maize or sorghum for summer feed to cut, and Sudan grass for a summer feed.

As to feeds that will produce milk; green wheaten hay and crushed oats are excellent and both grow on the holding. If purchases have to be made from outside, nothing beats bran. The best way to give cows salt is double handfuls to one kerosene tin of water. Pour this on the chaff and mix it well into the feed. This will help to keep the cows in good order. To feed cows for the stock market soaked barley during the winter months will prove the best, with a liberal supply of chaff and green hay.

[*Papers Read at Conferences.*]

PIGS.

For weaners there is no feed that is easier to feed or better for pigs than skim milk and pollard. Do not feed too much at one time; if necessary, feed three times a day.

Farmers must give some consideration to the type of pig they are feeding, and if for pork, have the Berkshire or Mid York fed on crushed and soaked barley. If for bacon, it is essential to keep the pigs growing and do not let them get too fat. When about a month off marketing, feed small feeds three times a day. For this, house refuse, skim milk and soaked wheat give good results.

Do not overfeed the sow that is to farrow, and after the pigs are born, give only skim milk and bran for two days; then give plenty of good food.

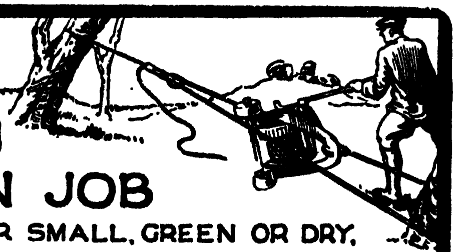
FARMING ON A MIXED FARM, AND IS MY PROFIT WHAT IT SHOULD BE?

[H. G. Fisher, Tatiara.]

When farm produce is low in price, like it has been for several years past, it is apparent to all that every effort should be made to get maximum returns for labour and capital expended.

Cropping Operations.—Are methods up to-date and carried out to the best of our ability, and are we sure the paddock to be fallowed for wheat is in a good fertile condition and capable of growing a good crop? If it is in a condition to grow a good crop, do we sow the best seed and the most suitable variety for our district, and also a good liberal dressing of super? If it is not in a condition to grow a crop, top dress it and leave it out to pasture, or, better still, sow Subterranean clover and Wimmera rye grass if the country is suitable for it. It would enrich the land, and if sheep were run on it the returns of their wool would be greater than the return from the ordinary crop of wheat we could expect from such a paddock. Another way to treat the paddock, if it could not be allowed to lie out of cereal growing so long, would be to grow oats, or a mixture of oats, Cape barley and rye for feeding-off purposes; it would help considerably to enrich the paddock.

Grow oats on land, if possible, before fallowing it for a wheat crop. Another cereal can be grown fairly cheaply in parts of our district—malting barley. The wheat stubbles can be burnt off and the land worked up and left until the wheat and oats have been sown. Barley does not need a long growing period, and it will generally show a fair profit on the expenditure outlaid. Local barley ripens earlier than lower down in the South-East, and it can be put on the Melbourne market when the maltsters are requiring it. I mentioned at the beginning of this paper, are our methods up-to-date? and I believe they may be on some farms a little overdone. Too many horses to do the work, and possibly a tractor lies idle a good part of the time. Are we trying to put in more crop than we should with the power that we have, and not working the soil as we should, which means reduced yields? Is the type of horse we breed the class that can do the work? When we have one or two to sell, are they the sort that the buyer is looking for? Apart from the profit, it gives one pleasure to see a good class of horse on the farm. Are our milking cows helping to keep us or are we keeping them? Some cows pay, others do not, and the writer is as guilty as anyone of having one or two that do not pay, but are we endeavouring to improve our herd? Good cows are as cheap now as they have been for a long time. A poor producer has to be milked and fed, which is time and money wasted, while a good cow pays for it.



GRUBBING IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS-POWER OF A

MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK.

Removing the most stubborn obstacles cleanly, with most roots intact.
Easy to handle, simple to operate, expeditious—its only need, regular oiling.
The Standard equipment will clean up everything over 1½ acres from one anchorage.
Each part designed for simplicity, easy handling, and long trouble-free service.

THE PRINCIPAL,
Agricultural College,
ROSEWORTHY.

Several good sires have been brought to the district of late, thanks to their enterprising owners. Farmers would be well advised to use them and improve dairy herds and, incidentally, incomes.

Sheep are one of the most profitable animals on the farm. Are we carrying as many as we should, or have we too many which are running short of feed in the dry autumn, or do we hand feed them to keep up their condition.

What about those pieces of land unsuitable for cultivation on the farm? Have we cleared them up and top dressed and made the most possible use of them? In our district, with a good annual rainfall, some of the poorer class of country has become the most profitable with the sowing of clovers and grasses and the annual top dressing with super.

Departmental officers have often stressed the fact that top dressing of pastures well repays the landowners. Are we still keeping that fat pig that Mr. Barlow denounces, or are we keeping the lean type that brings the highest market rates?

TOBACCO GROWING IN MURRAY IRRIGATION AREAS.

[R. E. C. Giles, Tobacco Instructor.]

Leaf curing operations have commenced at Barmera, giving definite results as to the suitability of this locality for the production of bright, flue-cured tobacco.

Experimental plots of tobacco of 24 light varieties were established in various parts of the Irrigation Areas, between Renmark and Cobdogla, with the assistance of 10 landholders.

Adequate protection from high winds was obtained by means of strips of sunflowers and maize, which were well established before the tobacco was planted out in the fields.

A considerable amount of damage was done to crops during December and January last, by insect pests—cut worm, stem borer, and leaf miner—but growers overcame these difficulties and have succeeded in growing reasonably sound leaf.

The tobacco has remained free from all disease while in the field stage, despite an outbreak of blue mould in the seedbeds at the Berri Experimental Orchard in October last, which was brought under control by means of benzol fumes.

The nature of the soil has proved to be the deciding factor in these experiments. Crops grown on the light, ashy, Loveday sand are turning out remarkably good leaf.

Plants have grown well, the leaf is full of gum and of good texture, and is ripening in a normal manner, colouring commencing and spreading without any sign of deterioration in quality, which is, unfortunately, apparent in leaf grown on the heavier soils in the vicinity of Barmera and Cobdogla.

There are two varieties of tobacco, namely, Bonanza and White Stem Orinoco, which seem most suited to this area. The former variety has done well in recent years in the North Queensland tobacco-growing districts.

As much seed as possible will be harvested from the successful plots of tobacco grown by Messrs. H. Wilkinson and L. Kerley, at Loveday, to ensure an adequate supply for next season.

Good leaf has been grown upon white Murray sand at Berri and Lyrup, but not upon a sufficiently large scale to justify a definite expression of opinion as yet.

The sandhills formed by drift at Barmera and Loveday have given poor results, despite heavy waterings and applications of fertiliser, and do not appear to warrant any further experiment.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April, 1935, to 31st March, 1936.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal; 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 29th February, 1936.	No. Eggs Laid Month of March, 1936.	Total Eggs Laid 1st April, 1935, to 31st March 1936.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.

DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

Free on Rail, Salisbury. **DELIVERY.—CHICKS—January to March.**
EGGS—January to February.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2oz., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

THE "HOME" TRAIN.

Work over for the day, man and maid, young and old are intent upon "getting home." All day they have been concerned with business, mostly someone else's business, for the majority of the homeward-bound travellers are salary or wage earners.

Have they—have you—found time for personal business.

The Commonwealth Savings Bank is open all day in City, Town, Village and Country Post Office, and its convenient services are therefore easily available to all.

Opening a Savings Bank account—and using it—costs little time and no money, and it will pay you well in the long run.

Commonwealth Savings Bank of Australia

Grenfell Street, Adelaide.

It is to the interest of every Farmer to belong to the AGRICULTURAL BUREAU.

Join the nearest Branch, or if you are not within driving distance of the nearest branch write to the General Secretary, Central Agricultural Bureau, for particulars as to how to form a Branch.

WOMEN interested in Agriculture should join a Woman's Branch. Full particulars on application.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE AT BEETALOO VALLEY, 12th MARCH.

Opened by the Hon. A. P. Blesing, M.L.C. (Minister of Agriculture), the Conference of Mid-Northern Branches of the Agricultural Bureau was held for the first time at Beetaloo Valley, on Thursday, 12th March. In addition to officers of the Department of Agriculture, there was an excellent attendance of delegates from district branches of the Bureau. Mr. P. Curtin presided, and the following papers were read and discussed:—"A History of Beetaloo Valley," by Mr. J. Arthur, Beetaloo Valley; and "Pea Growing," by Mr. W. F. Wurst, Laura.

Conference decided "That the Bush Fires Act be amended to permit of stubble burning being carried on between the hours of 9 a.m. and sunset." "That the 1937 Conference be held at Koolunga." "That the points awarded for 'apparent yield' in crop competitions be reduced to 30 and the points for 'trueness to type' increased to 20."

The Hon. A. L. McEwin, M.L.C. (Chairman of the Advisory Board of Agriculture), presented the prizes to the successful competitors in the Northern Crop Competitions.

In the evening, Mr. Spafford gave an address, illustrated with lantern slides, on "A Tour of the Southern Hemisphere."

CONFERENCE AT BORDERTOWN.

The Conference of South-Eastern Branches of the Agricultural Bureau, which was held at Bordertown on 1st April, was sponsored by the Tatiara Branch, and the three sessions (morning, afternoon, and evening) were presided over respectively by Messrs. F. Densley (Tatiara), G. D. Butler (Wolseley), and H. Warland (Mundalla). The Conference was opened by Professor Perkins (Director of Agriculture) representing the Advisory Board of Agriculture, and papers were read by Mr. H. G. Fisher (Tatiara) on "Farming on a Mixed Farm" and Mr. A. E. Milne (Tatiara) on "General Feeding of Stock." Mr. C. T. McKenna, B.V.Sc. (Veterinary Officer, Stock and Brands Department), addressed the Conference on Parasites Attacking Farm Stock, and Mr. C. A. Goddard (Assistant Wool Instructor, School of Mines) also gave an address on the Classing and Marketing of Wool. Officers of the Department of Agriculture assisted in discussions and replied to a large number of questions submitted by members of branches.

The evening session was devoted to an address (illustrated by lantern slides) by Mr. W. J. Spafford (Deputy Director of Agriculture) on "A Tour of the Southern Hemisphere."

It was decided to hold the next Conference at Bordertown. Other resolutions carried were: "That a sheep expert be appointed for South Australia" and "That time for burning under the Bush Fires Act be not altered in any way because of the great danger of fires getting out of control and doing a lot of damage if burning is done at an earlier hour than allowed at present."

CONFERENCE AT KYBYBOLITE.

Branches of the Agricultural Bureau situated in the Lower South-East held their Annual Conference on 8th April for the first time at Kybybolite. Mr. J. M. Wray occupied the chair, and the opening address was delivered by Mr. P. J. Baily (Member, Advisory Board of Agriculture).

Mr. L. J. Cook (Manager of the Kybybolite Experimental Farm) read a paper on "A Comparison of Results of Wimmera Rye Grass and *Phalaris tuberosa*," and Mr. E. C. H. Schinckel gave a historical outline of the Kybybolite Farm, and urged an extension of its scope of operations.

Addresses were delivered by Mr. A. C. H. Richardson (Chairman of the Unemployment Relief Council) in which he outlined a scheme to assist producers to clear land, and Mr. R. C. Scott (Supervisor of Experimental Work) who spoke on his recent tour of New Zealand.

At the session devoted to Free Parliament it was decided:—"That the 1937 Conference should be held at Coonawarra"; "That this Conference recommends to the Government that steps be taken to augment the scope of work of Kybybolite Farm in such a way as to make it a National Research Farm"; "That the Department of Agriculture take over the offices of veterinary surgeons in South Australia, and that a veterinary surgeon be appointed for the South-East"; "That a sheep expert be attached to the Department of Agriculture for the benefit of farmers of the State."

On behalf of the Advisory Board, Mr. Baily presented Life Membership Certificates of the Agricultural Bureau to Messrs. L. S. Davie and L. J. Cook.

The evening session was devoted to an address by Mr. W. J. Spafford (Deputy Director of Agriculture), "A Tour of the Southern Hemisphere."

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, 25th March, 1936, there being present:—Hon. A. L. McEwin, M.L.C. (Chairman), Messrs. A. M. Dawkins, S. Shepherd, J. B. Murdoch, Geo. Jeffrey, F. Coleman, H. N. Wicks, R. H. Martin, Dr. A. E. V. Richardson, Prof. A. J. Perkins, and H. C. Pritchard (Secretary). Apologies were received from Messrs. P. J. Baily and A. J. Cooke.

Blackwood Experimental Orchard.—Mr. H. N. Wicks presented a statement regarding the reorganisation of the work being conducted by the Blackwood Experimental Orchard. The Board suggested certain additions, and asked that the report be presented again at the next meeting.

Oenological Course at Roseworthy College.—The Secretary reported that the Government had approved of an advanced course in Wine Making at the Roseworthy Agricultural College.

Crop Competitions.—Lower North Conference resolution:—"That when a crop is grown on the share system, the following provisions in relation to prizes shall apply: A joint entry may be made, and any prize won be divided between the owner farmer and the share farmer, unless either party refuses to share in the cost of the entry, when the entry may be made separately by the owner farmer or share farmer—any prize to go to the party making the entry."

Decided to endorse the resolution and to transmit it to the Crop Competition Committee for consideration.

Crop Competitions.—Mid-North Conference resolution:—"That the points awarded for 'apparent yield' in Crop Competitions be reduced to 30, and the points for 'trueness to type' increased to 20."

Decided to forward the resolution to the Crop Competition Committee for consideration.

New Branches.—Approval was given to the formation of Women's Branches at Echunga and Strathalbyn.

Life Members.—Approval was given for the addition of the following names to the roll of Life Members:—Messrs. H. C. Roediger, A. E. A. Skipworth, W. D. Wemyss (Yeelanna), J. A. Lane, J. P. Burchard (Tantanoola), A. Bradley, L. S. Davie (Kybybolite), J. M. Cheriton (Strathalbyn).

New Members.—The names of the following persons were added to the rolls of existing Branches:—Arthurton—H. R. Lamshed, Howard Bowman; Beetaloo Valley Women's—Miss R. Andrew; Blackwood—C. F. Scheror, W. N. Halstead, J. Austin Lambert; Boor's Plains Women's.—Mrs. P. Vidal, Miss L. Lamshed; Brentwood—R. Wilson; Clarendon—Ron. Sowerby, E. Gould; Coonawarra Women's—Mrs. W. Davis; Currency Creek—W. W. Ellis; Echunga—J. Christinger, A. W. Mooney; Goode—C. Lutz; Hartley—B. H. Wagenknacht; Hope Forest—Gleeson DeCaux; Karte—L. Fiebig, Gordon Atze, H. Gale; Kybybolite—W. Davie; Kybybolite Women's—Miss C. M. Johnson; Maltee Women's—Miss D. Edson, Miss N. Schwarz, Miss D. Bassham; Mount Gambier—M. Kilsby; Mundalla Women's—Miss D. Menzie, Mrs. Ray Hinge; Mypolonga—G. Llewellyn; Narridy—John Renshaw; Parilla Women's—Mrs. H. Schumann; Parrakie—W. Watts, Albert Edwards, Ernest Wheare, Eric Ross, O Heinzel, A. D. Sanderson, N. Catford; Redhill—Jack Morgan, Glen Crouch, Jack Miller; Rosedale—Garth Atkin, Frederick C. Wilson, Claude A. Gwynne; Roseworthy—C. Brooks; Saddleworth Women's—Mrs. J. D. Garrett; Sheoak Log Women's—Mrs. B. Window, Mrs. G. Heinjus; Snowtown—J. F. Kelly; Tantanoola— — Blowes; Wandearah—Arnold Eagle; Wasleys Women's—Mrs. — Hannan, Miss G. George: Wirrabara Women's—Mrs. Annie Edwards; Yandiah Women's—Mrs. A. Francis, Miss A. Kupke, Miss D. Borgas; Yeelanna—A. Doley, N. Glover.

Foundation Members of New Branches.—Echunga Women's—Mrs. G. Edmonds, Mrs. P. Duffield, Mrs. F. Wickham, Mrs. A. Hauber, Mrs. E. J. Dennis, Mrs. A. J. Feder, Mrs. T. E. Hincks, Mrs. C. McDonald, Mrs. W. H. L. Norman, Mrs. E. Liebelt, Miss P. Henderson, Mrs. J. Boon, Mrs. B. Plane, Mrs. R. Davis, Mrs. H. Smith, Miss — Hough, Mrs. H. Gilbert, Mrs. A. Golding, Mrs. A. W. Mooney; Strathalbyn Women's—Mrs. A. S. Deer, Mrs. S. S. Arnold, Mrs. C. M. Hudd, Mrs. J. M. Hudd, Mrs. R. Aworth, Mrs. L. J. Hall, Mrs. F. W. Allison, Mrs. L. E. Stirling, Mrs. G. Sissons, Mrs. K. R. Westley, Mrs. J. Collett, Mrs. R. G. Martin, Mrs. J. Bowden, Miss O. Bottrill, Miss O. Westley, Miss D. Sissons.

Conferences.—The Secretary reported that Conferences would be held at Bordertown on April 1st, and at Kybybolite on April 8th.

Change of Branch Name.—The name of the Tweedvale Branch was altered to Lobethal.

Several items were taken in Committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on 1st April, 1936:—

BUTTER.—A seasonal shrinkage in supplies continued throughout March, particularly in top grade, and producers are now anxiously awaiting the break in the season to check the downward trend. The demand for choicest quality was strongly maintained, and a hardening in prices was recorded. The London butter market, after sagging badly because of the difficult European situation, has shown improvement, and prices there firmed 4s. to 5s. per cwt. There is still a surplus of lower grades to go forward, and it seems probable that there will be no break in the continuity of shipments this year. Present prices in Adelaide are:—Choicest creamery fresh butter in bulk, 1s. 4½d. per lb. Prints and delivery extra. (This price is for local sale only, and under the quota system the equalised price manufacturers will receive will be 1s. 9/16d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines from 1s. to 1s. 1d. per lb. for choicest; stores, 8d. to 9d. per lb. (These prices are subject to equalisation levies.)

CHEESE.—In the South-East, where most of this commodity is manufactured, conditions have rapidly altered so that the supplies of cheese are now much less than a month or two ago. Exporting was continued throughout March, but is now about finished. London buyers have been well satisfied with the quality of the South Australian article so that there has been no difficulty in quitting stocks from time to time. Local prices are:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. to 1s. 1d. per lb.

EGGS.—Supplies are now falling away very rapidly, and with stronger local and Interstate demand values are likely to go higher, especially when the cool weather sets in. Present rates are:—Ordinary country eggs, fair average quality, from 7d. per doz. net; selected new laid, clean eggs, full-sized, to 1s. per doz. net.

BACON.—The demand for the established brands of bacon was well maintained, and the turnover was better than usual for this time of the year. Curers have ample stocks which are being placed on the markets from day to day, and no difficulty was experienced in supplying the demands. Hams have been somewhat slow of sale, and Interstate orders were necessary to reduce stocks. Values are:—Best quality sides, 9d. to 9½d. per lb.; middles, 9½d.; heavy middles, 8d. to 8½d.; rolls, 8d. to 8½d.; hams, 11½d. to 1s.; cooked, 1s. 2d. to 1s. 2½d. per lb.; lard, bulk, 5½d. to 6d.; prints, 6½d. to 7d. per lb.

ALMONDS.—The supplies of the new crop are now arriving in much greater quantities each week, and turnover was well maintained, present quotations being:—Softshells and Brandis, 8½d. to 9d.; hardshells, 5d. to 5½d.; kernels, 1s. 9½d. to 1s. 10½d. per lb.

HONEY.—No alteration was made in prices throughout the month although in some instances concessions were given to effect sales. Stocks held by merchants are still very heavy, but it is to be hoped that during the winter these will be reduced. Quotations area:—Prime quality clear extracted, 2d. to 2½d.; lower grades, 1d to 2d. per lb.

BEESWAX.—Has been short in supply for the last few weeks, and heavier quantities could be placed at:—1s. 2d. to 1s. 2½d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our salerooms, which are in every way the best equipped in the State. The demand for all classes of birds was steadily maintained, but prime, heavyweight stock met with the keenest interest, as poulterers were purchasing for their Easter requirements and having the birds placed away in cold stores. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. to 4s.; nice-conditioned cockerels, 2s. 6d. to 2s. 11d.; fair-conditioned cockerels, 1s. 9d. to 2s. 4d.; chickens, lower; heavyweight hens, 2s. 3d. to 3s.; medium hens, 1s. 8d. to 2s.; light hens, 1s. to 1s. 5d.; couple of pens of weedy sorts, lower; prime young muscovy drakes, 3s. to 3s. 8d.; young muscovy ducks, 1s. 9d. to 2s. 3d.; ordinary ducks, 1s. to 1s. 9d.; ducklings, lower; geese, 2s. to 3s. 6d.; goslings, lower; turkeys, good to prime condition, 8d. to 9½d. per lb. live weight; turkeys, fair condition, 6d. to 7½d. per lb. live weight; turkeys, poor and crooked breasted, lower; pigeons, 3d. each.

POTATOES.—New season's, 8s. 6d. per cwt.

ONIONS.—Brown Spanish, 8s. per cwt.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from 1st August, 1934, with the following exceptions:—Life members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

SOLDERING.

The following paper was read by Mr. E. A. Wilksch at a meeting of the Greenock Branch on 16th December:—

Soldering cannot be fully mastered at once, but a certain degree of efficiency may be attained with a little practice, providing, of course, that one has reasonably good appliances with which to work. First, a good iron is necessary; it should be neither too blunt-nosed nor too heavy. A heavy iron would be found very clumsy. On the other hand, the iron should not be too light as it will not retain its heat for any length of time. It is a great asset and time-saver to have two irons of different weight or size, for access is more easily gained to some places with a reasonably small iron than with a bigger one. Another advantage of two irons is that one may be heating while the other is being used.

Perhaps just as important as the iron is an efficient flux. There are several fluxes such as resin, spirits of salts, and other acid solutions. The most efficient one is Baker's Soldering Fluid. Spirits of salts is also not to be belittled, but it has to be first broken down. Baker's fluid, in common with several other commercial solutions, is put on the market in tin containers, and when purchased, it should be transferred from its original container to a bottle of convenient size, preferably one with a screw or clip top, for convenience as well as security. If this is not done the solution will become discoloured through rust having developed. A feather is quite useful in applying the solution. The remaining necessities are a good 50-50 solder, a rag to wipe the iron free of ashes, sandpaper or emery cloth to clean the place to be soldered, and a fair seasoning of patience. Acid and resin-cored coils of solder are also more used than previously. As regards the heating element, a fire of good coals is all that is required—mallee or she-oak are to be preferred. A blow-lamp is also quite suitable.

To tin an iron, clean it well (this is important) then get it very hot. Tilt a lid or similar receptacle and pour into it a small quantity of fluid. With the hot iron (wiped to remove ashes) drip some solder into it and follow by dipping the iron into it, and with its aid melt the solder. By careful manipulation, endeavour to coat the end of the iron as far as necessary with the molten metal. A different method is to rub the cleaned hot iron in a small amount of solder on a block of sal-ammonia. After tinning an iron by this method several times a slight indentation is made in the block, which greatly facilitates the operation. It is not necessary to touch on the simpler forms of soldering beyond stressing the importance of not applying more flux than is necessary, because molten solder has a property of spreading to places where it is not wanted.

A person sometimes has the unpleasant experience of not being able to persuade the solder to adhere to an apparently clean surface. This may be overcome by giving it a rather more generous application of flux.

To solder a fairly large hole, drill it out well into the sound metal, drilling from both sides if possible, in order to clean it. Cut a small piece of brass or other metal and file it to fit roughly. Give all a good application of flux, and keep it in place with a handful of paper. With a well-wiped hot iron convey a drop of solder to the place to be soldered and keep the iron on it for a moment, and a neat, strong mend will be effected. One advantage of this re-inforced mend is that it is practically flush with the surrounding surface. Should the hole be smaller, and therefore not lend itself to this type of repair, but yet be difficult to cover with solder, hold directly under the hole a handful of paper. Besides keeping the solder in place it keeps the hands from becoming uncomfortably hot. After an article has been soldered the place should be wiped or, if possible, washed in warm, slightly soapy water in order to remove surplus flux, otherwise it will undoubtedly set up corrosion in the form of rust, or, in the case of brass and copper, verdigris. (Secretary, A. Schubert.)

THE PROBLEM OF THE YOUNGER GENERATION.

The above was the subject of a paper read by Mr. C. Menadue at a meeting of the Chapman's Bore Branch on 11th November. In the course of the paper he pointed out that the position of the younger generation would be very much different from that of their fathers, because of changed economic conditions. Farming would call for only the best equipped and most efficient men, who must have a good knowledge of everything that concerned a farmer's business. Many of the boys of the district were not equipped to face such a position, because they had not had the opportunity of acquiring a good education. The poor-soil lands of the district offered many problems. In consequence youths should be trained to enable them to get the most from their labours under such conditions. In all trades, arts, and crafts it was necessary for a boy to have a technical school training, yet very often a farmer's son was allowed to go through life untrained and unfitted to cope with the difficult problems of farming. Parents should try to impress upon their sons the importance of the Agricultural Bureau as a means of gaining knowledge of the best farming methods for the district. (Secretary, J. P. Krollig.)

FAR NORTHERN CROP COMPETITION.

The presentation of the prizes won in the 1935-6 Far Northern Crop Competition took place at the residence of Mr. W. G. Gregurke, of Wepowie, on 19th March. Mr. H. G. Kupke (Morchard), Chairman of the Competition Committee, presided over an excellent attendance. Mr. F. C. Richards (Assistant Secretary of the Agricultural Bureau) presented the following trophies:—First prize, W. G. Gregurke, casserole dish; second prize, T. F. Orrock, E.P. fruit stand; third prize, E. H. Hampel, of Wilmington, E.P. dish.

It is worthy of note that in each of the Competitions that have been held in the Far North District, Mr. Hampel has on each occasion been successful in receiving a prize, a record which it is doubtful if any other competitor in the State has achieved.

To encourage the growing of wheats of high milling quality, the Millers' Association of South Australia this year donated five guineas to each District Competition, on the condition that the prize money should be distributed amongst the successful competitors, provided their crops were not one of the following varieties:—Gallipoli, Free Gallipoli, Ghurka, Waratah, or Nabawa. Mr. G. Addison, on behalf of the Association, made the following presentations:—First prize, W. G. Gregurke, gold watch; second prize, T. F. Orrock, 8-day clock. Items were contributed by Miss Whittle, Mr. F. C. Richards, Miss Roocke, Miss Davill, Mr. Noblett, Miss Rogers, and Miss Schultz. The members of the Wepowie Women's Branch provided supper, and the evening concluded with dancing.

HARVEST REPORTS.

GOODE.—Ten members attended a meeting on 4th March, when harvest reports were given, the majority of members reporting best results from Nabawa. Mr. C. P. Linke reported that for a number of years Florence and Quality had given him the best returns. Mr. J. Kelly stated that a fine-looking crop of Ford had been very disappointing, Nabawa and Wagga yielding much better. Ranee was said by some members to be suitable for the district, and all members were advised to try it. Mr. B. A. Linke stated that Gluford and Nabawa had, for some years, given best results on his property.

PYGERY.—At a meeting held on 10th March Mr. R. Woodrup reported that crops were good until October, when take-all and hay-die commenced to develop. His best return, six bags per acre, was from Waratah sown with a drill, while the same seed sown with a combine on the same day and on well-worked land yielded only three bags. Waratah and Merriden sown late on grassland returned two and a half bags. On fallow Merriden was badly affected with take-all and yielded four bags. Mr. E. H. Edmonds's best wheat on stubble was Ford, followed by Ranee and Nabawa. Mr. G. P. Symonds reported that all wheat was sown on land which had carried oats last year and at the rate of 50lbs. seed and 60lbs. super. Take-all was bad except in the headlands (drilled twice), where there was none. Mr. W. M. Heath reported fallow crops more affected with take-all than grassland crops. Sword yielded best, with a return of five bags. Nabawa and Ranee were better than Waratah. Mr. A. Day reported that Ranee on grassland, which had been ploughed and sown with a combine at the rate of 50lbs. seed and 70lbs. super, yielded six bags, Nabawa on new land five bags, and Waratah on stubble four bags.

MALTEE.—At a meeting on 5th March 11 members attended and gave reports of their harvest results. Mr. C. T. Schwarz had the best crop with a yield of 18bush. from Late Gluyas; Early Gluyas returned 15bush. The average was 11bush. and was the best in the district. Mr. L. M. Martin reported a return of 11bush. from Felix. Dry seeding conditions and take-all and rust lowered the returns considerably. The average for the district was 6bush.

CHAPMAN BORE.—Fifteen members attended a meeting held on 10th February, when harvest returns were discussed. Mr. C. H. Randell reported oats sown on grassland with 1bush. seed and 75lbs. super averaged four bags. Wheat sown with 54lbs. seed and 90lbs. super returned 7bush. Mr. R. Ackland stated that oats sown on stubble with 40lbs. seed and 45lbs. super returned a useful cut of hay and a satisfactory yield of grain. Sultan had been the best wheat variety. Mr. A. Hill sowed oats on fallow at the rate of 40lbs. seed and 75lbs. super. The crop was badly infested with weeds, especially Cape weed, and the yield was low. Wheat sown on grassland at the rate of 50lbs. seed and 75lbs. super returned 7bush. Mr. C. Menadue reported Early Burt oats sown on drifty sand with 50lbs. super and 60lbs. seed cut approximately half a ton of hay per acre. Algerian oats sown on fallow with 50lbs. seed and 50lbs. super cut one ton per acre. Wheat on fallow was sown on sandy soil with 55lbs. seed and 80lbs. super. Dan averaged three bags, Ranee 10bush., Waratah 11bush., Baldmin three bags, and Nabawa three bags. Mr. H. Burbridge reported that oats sown with 60lbs. seed and 45lbs. super averaged four bags on fallow and one bag on stubble. Wheat sown with 45lbs. seed and 45lbs. super on new land yielded two bags from Nugget and Dan one bag. On second-year land, sown in May, Nabawa returned two and a half bags and Federation one bag. Mr. W. Whitehead had received a yield of two bags from oats sown with 40lbs. seed and 45lbs. super. Wheat sown with 45lbs. seed and 70lbs. super returned four bags on fallow land and two and a half bags on stubble. Oat crops throughout the district were badly damaged by wind, some being reduced to a total loss.

ARTHURTON.—At a meeting held on 18th February, with an attendance of 14 members, Mr. Brine reported that crops had been rather light. Smutproof wheat had shed badly during rough weather. Barley returned approximately six bags per acre. Mr. Rudd reported a yield of six bags from barley and six bags from Ranee wheat. Wild turnip and stormy weather conditions had greatly reduced wheat yields. Some crops had also been affected by a frost which had occurred on 25th October. Mr. R. Honner also reported damage by frost. Mr. S. K. Coleman stated that stormy weather had done much damage, some patches in the Ford and Sword returning little or no grain. He had grown Plumage Archer barley, but owing to the tendency for the heads to fall off he did not recommend the variety. Mr. L. Clasohm stated that Ghurka and Ranee varieties had not been so much affected by the bad weather conditions because they ripened earlier than Ford and Sword, in which there had been considerable loss. Fallow crops had returned 11 bags per acre and stubble land eight bags. Barley yielded about 27bush. Mr. L. Short had best results from Sword—about 11 bags per acre. Other varieties yielded seven to eight bags and barley seven bags. Mr. E. Palin's wheat average was 28bush. to 29bush. and barley averaged six bags. Mr. S. Henderson reported that Ford returned eight bags, Sword over eight bags, and Aussie and Ranee 30bush. per acre. Plumage Archer barley on grassland had yielded 10 bags per acre.

HILLTOWN.—A meeting on 3rd March, attended by 26 members, was the best since the Branch was opened. Mr. R. L. Sluggett was congratulated on his success in winning the Midland Wheat Crop Competition. *Crop Reports.*—Good spring rains, following a fairly dry winter, resulted in crops yielding higher than was expected. The absence of disease was noticeable, no rust being reported and only a little flag and loose smut. Some heavy yields were recorded, noticeably from Gallipoli and Ghurka. The meeting discussed the advisability of continuing with such varieties. Some members held that, in view of their low milling qualities, they should be discarded for national reasons.

BOOLEROO CENTRE.—At a meeting held on 6th March, members gave the following harvest reports:—

F. H. Reichstein.—The season 1935-36 was a disastrous one, particularly to those farming outside Goyder's line of rainfall. The useful rainfall period (from May to November) amounted to only about 5in. Had it not been for the splendid rains in October, 1934, penetrating the subsoil and conservation of that moisture the season would probably have been a failure in this district; as it was the average was below

5bush. The first seeding rains did not arrive until July. August was not a wet month, but October was better than usual, saving the situation. The best wheats were Bobbin, which returned 9bush., dry sown, and Dundee, 8bush., wet sown. Ghurka was third, averaging 6bush., while Ranee went from 3bush. to 4bush per acre. Dundee is going to be a good wheat for our district; it is as early or perhaps a little earlier than Ranee. Bobbin is a good wheat too, for as far as bleaching from rain is concerned it is far ahead of Ranee, as Bobbin sheds the rain, while with Ranee it runs straight into the head. But as usual with all our good standing and yielding wheat the stubble is practically useless as a dry fodder for stock. My wheat was too short to cut hay this year. In this district it is good practice to use a stripper on some of the crop to save the cocky chaff, besides a stripper does not ruin the stubble as a header does. It is a mistake to reap all the crop with one machine. There was a wonderful sample of wheat here this year, perhaps the best ever.

T. H. Borgas.—Crop up to the average over the past 14 years. Average, 19bush.; best wheat, Ghurka, 21bush. Early sown wheat was the best. To cultivate fallow before seeding is very beneficial. I have saved cocky chaff for the past 19 seasons and have been able to get rid of it each year. It must be taken care of.

R. W. Reichstein.—The Dundee variety was a failure this year as far as milling for flour was concerned. Sword variety was good. The soil conditions play a big part so far as the quality of a wheat goes.

Chas. Patterson.—Three varieties of wheat sown—Sword, Ranee, and Nabawa. Sword germinated and came up poorly; soil of limestone nature; it had a good head and was of a wonderful sample. Ranee, best average yield. Nabawa, splendid sample; where the land had been cultivated three times and where the moisture had been conserved there was a tendency to malt badly, but on stubble fallow the grain germinated much better; average was 10bush. The cocky chaff should be saved, and for this purpose a stripper harvester is best. A header destroys the stubble and header cocky chaff is not as good.

W. Sewsmey.—Ranee was the best wheat and was a perfect sample. Carawa was the best of the late wheats. Sword is not suited to this district. It was inclined to turn and was not nearly as good a sample as some other wheats sown.

W. A. Mills.—The sample was unquestionably the finest I have ever harvested, both as far as weight and looks are concerned when one considered the poorness of the stubble and the very light rainfall that we had. Ranee averaged 10bush. Nabawa averaged 18bush. on a field that was exceptionally well worked and was planted under favourable conditions. I had some experimental crops on stubble land sown with oats and various dressings of ammonia and super mixed, but they were practically a failure, making no growth until late in the year. In this district the saving of cocky chaff is essential, and the best way of doing this, in my opinion, taking into consideration the stubble afterwards, is by the stripper and winnower.

The following paper, "The Advantages of a Weed Cutter," was read by Mr. F. H. Reischstein:—"There are two types of weed cutters—the V-shaped and the straight, but the straight type is the best suited to any undulating ground, such as claypans and watercourses; of course, it will not work in stony or boulder country. This implement is made up of old tine scarifiers, and can be made very cheaply. Most farmers who have a blacksmith's shop can make one by hiring a smith for a few days. My cutter has a cut of 15ft. 3in. and the blades are cut from a 16ft. length of 4in. x ¼in. plough plate steel and sharpened one side. This steel cost 22s. 6d. per hundredweight; one cut makes two blades. The cost of my weed cutter was approximately as follows:—

	£	s.	d.
Two large wheels at 10s. each	1	0	0
Two small wheels at 16s. each	1	12	0
Two old scarifiers (minus wheels)	0	10	0
One bag coal	0	5	0
One set blades, 4in. x ¼in.	0	11	6
Smith's wages (eight days at 6s. 6d. a day) ..	2	12	6
Two bars ⅝in. iron	0	7	0
One 16ft. main axle	0	10	0
Miscellaneous	0	10	0

It can be seen, therefore, that this is not a very expensive implement. Since the rains, up to 35 acres a day have been done with 12 horses, but nine or 10 horses will work it comfortably. The big advantage in working over fallow in the summer time is that all the weeds are killed without disturbing the seed bed; also a large acreage can be gone over in a few days compared with using a combine. This year I have worked 400 acres out of 500 acres of my fallow and I am convinced that it is going to give better results than cultivated fallow. In the lower rainfall district harrows are not used nearly enough. There is less evaporation in fallow that is left harrowed down."

EXPERIMENTS WITH NITROGENOUS FERTILISERS.

At a meeting of the Mundalla Branch, held on 19th February and attended by 16 members, Mr. E. L. Milne reported on experiments he had conducted with nitrogenous fertilisers. The experiments were carried out with 1 and 1 super and ammonia fertilisers on stubble and grassland ploughed and sown to oats. Results were disappointing as regards yield of grain; the improvement in grain yield over the ordinary super crop not being sufficient to warrant the extra expense and work. The 1 and 1 mixture was rather difficult to get through the drill. The crops receiving the 1 and 1 mixture had a better appearance than the crops sown with super only. Mr. Milne considered that if the crops had been cut for hay the nitrogenous fertiliser might have shown better results.

THE COMBINE.

A paper, "The Combine," was the subject of a meeting of the Murraytown Branch held on 29th February, and attended by seven members. The writer, Mr. E. B. Pitman, stated that it was approximately 20 years since the combine came into general use. To-day only a few farmers still used a cultivator and seed drill for sowing crops. The combine was satisfactory so long as there were only small weeds to kill at seeding time, but where there were large, strong weeds in wet soil no combine would tear them sufficiently to kill them in the one operation. The driver of a combine should be careful to see that he neither overlapped nor cut too wide. He should also keep a watchful eye on the sowing of both seed and super. All oil holes should be kept clean. With spring tyne combines one should make sure that no tyne had moved along the float and thus was not cutting its proper share of the soil. The I.H.C. combine was a fairly light-draft type with good spring tynes which would withstand a lot of work before breaking. It had chain-driven gears, and the quantity of super being sown could be adjusted while the machine was in use. Bad points were that the hopper was too close to the wheels. In hilly, stony country stones were picked up and fell between the hopper and the wheels, causing broken spokes. Wheels were of rather light construction. The team pulling gear was too narrow and allowed too much lash. The Massey-Harris machine the writer had used was of the rigid-tyne type, 16 hoe. It had good strong wheels and a good team pull. Owing to the many bars running across the floats, any rubbish picked up stayed in the machine and it was difficult to clean it out. On stony land the writer had had numerous breakages in the super drive. For the above reasons he considered it chiefly suitable for clean land. The tynes and floats were of strong construction. The H.B. had a good clearance between the hopper and the strong, sturdy wheels. The team gear was arranged in give a minimum of lash with the fore carriage. It possessed a disc-gear drive which seemed fairly reliable. If one was prepared to use plenty of strength to pull it, the pressure springs could be closed up enough to make it almost a set machine, which would then tear up the hardest of set soils where a spring tyne would ride over the surface. The crossbars of the floats were inclined to give way to the side-thrust of the tynes when the machine was turning. No difference in crop returns had been noticed between the use of machines with back and middle sowing tynes. *Discussion.*—Mr. Reichstein considered that the I.H.C. chain drive resulted in lighter draft than with other combines using gear drives. In several years operations of centre sowing and back-row sowing combines they had not been able to notice any difference in the yield. Broken spokes were best replaced by plain spokes with nuts inside the hub and outside the tyre, screwed down tightly.

BULK HANDLING OF GRAIN.

At the March meeting of the Wirrilla Branch Mr. S. Dennison, M.P., gave an interesting address from information obtained during his recent visit to Western Australia, when he accompanied a Parliamentary party to investigate bulk handling of wheat, gathering much information from the Co-operative Bulk Handling Co. and other users.

Mr. Dennison explained that at Fremantle there were two loading gantries converted for dealing with wheat in bulk at a cost of £160,000, and it was anticipated that £439,000 would be required to complete terminals to handle the total crop of about 23 million bushels.

The gantries seen were worked by worms through long troughs which could move 180 tons an hour each. Overhead elevators, buckets, and chutes were worked filling ships, the wheat being poured anywhere into the ship. An allowance of 2½ per cent. of deck capacity below was stored on deck to fill up when settlement of cargo took place.

A duplicate Clarke shovel was used for emptying railway trucks, and that way two men loaded two 14-ton trucks in 22 minutes.

The Western Australian railway trucks were fitted out for bulk grain by adding hessian liners and canvas extensions stiffened with cane to increase carrying capacity, sheeted with tarpaulins, and fitted with aproned coverings to the conveyors to prevent spilling, all fittings being the property of Bulk Handling Co. A subsidiary boosting elevator was worked from a reserve to cover any lull in filling. At terminals a toll of ⅜d. per bushel was made, which provided for repayment of capital, interest, depreciation, and insurance, and a ⅛d. to Westralian Farmers for services rendered. It was pointed out that at 4½d. bushel it would be possible to pay off in 10 years all the cost of installation to handle all the Western Australian crop, and the equipment would then become the property of the growers.

The delivery warrant issued for receiving wheat was negotiable, but the wheat remained the property of the farmer till he sold. Storage charges of one-tenth of a penny a month were made from 15th March till 31st October; after that date the company had the right to sell.

Mr. Dennison quoted balance-sheets obtained from two farmers. A Mr. Uppill on 16,066bush. showed a profit of £157 0s. 9d., or 2.48d. per bushel. Mr. Ackland showed a profit of £111 5s. on 11,400bush.—2.219d. per bushel, and a saving of three weeks' harvesting.

Mr. Dennison outlined a scheme which has been drawn up to get bulk handling in South Australia from methods successfully used in Western Australia and New South Wales, and urged all present to work to get bulk handling as the most successful way of handling wheat and saving expenses.

REVIEWING THE PRESENT SYSTEM OF FARMING.

Mr. C. Rechner read the following paper before an attendance of six members at a meeting of the Kilkerran Branch held on 9th March:—As the rainfall over the greater part of this district is probably in the neighbourhood of 15in., we cannot indulge in the intensive pasture improvement which may be possible in districts with a rainfall of 20in. to 25in. However, as the ideal rotation for cropping should include one year letting the land lie out as pasture, a heavy dressing of superphosphate will do much to encourage our natural grasses and help to improve the soil for the following crop.

In the past we have not paid enough attention to encouraging clovers and other natural fodder plants to establish themselves. Our present system of farming, on the contrary, has had the effect of killing them out.

A good practice carried out successfully in the middle north is to sow about 2lbs. of lucerne per acre with the wheat crop at seeding time. This will establish itself sufficiently to withstand being fed off when the stock are turned into the stubble, and will grow up after a summer rain. If the stubble is burned, the lucerne withstands the burn well. In fact, it appears to stimulate its growth, even surviving the shallower cultivation in preparation for the barley crop.

The relative high price of land and low prices hitherto received for wool has necessitated farmers in this area being mainly restricted to the growing of wheat and barley in conjunction with the raising of fat lambs.

However, I consider that in view of the low prices ruling for barley at the present time some alteration in our rotational system of fallow-wheat-barley could be safely undertaken. In view of the enhanced prices for export lambs and the improvement in the price of wool, a crop of oats could be substituted for barley. The oats could be dealt with as pasture to fatten lambs and run sheep on. If such land were fallowed the following year, a big improvement should result in the ensuing wheat crop.

If the area proved too large to feed down, a portion of it could be harvested and fed to the sheep during the autumn, when feed usually is scarce.

By this time the lambs will have been marketed, and a larger flock of ewes could be carried without danger of over stocking if oats were fed in addition to their pasture.

The land would not be subject to over cropping and would be in good heart, so that, when more remunerative prices are offering for barley, we could revert to the old system of fallow-wheat-barley without a great deal of inconvenience in the change over.

CARE OF SHEEP.

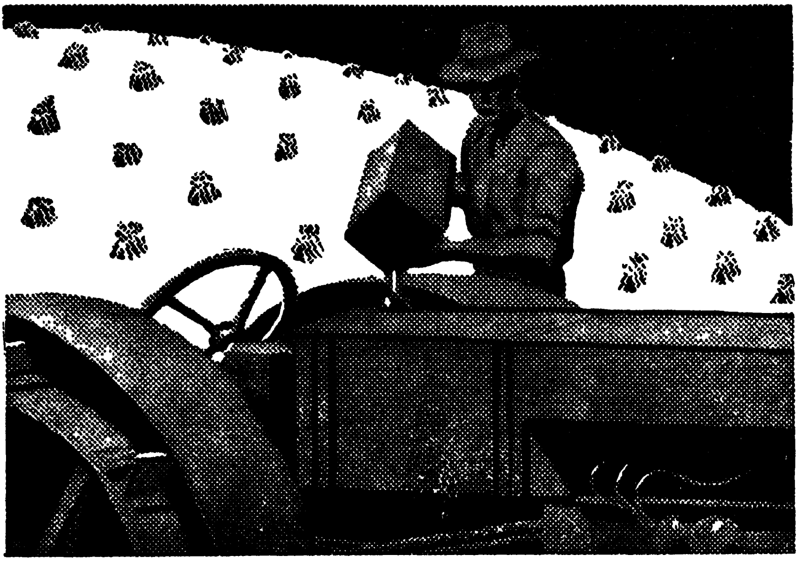
In the course of a paper read at a meeting of the South Kilkerran Branch on 2nd March, Mr. B. W. Schulz recommended inspecting the flock a week or two before shearing and cleaning them up around the crutch with a pair of blades in order to give the machine shears a better chance to get close to the skin. During shearing time more care should be taken not to handle the sheep in any way roughly. Sheep owners should attend the shearing more often and not allow shearers to handle the sheep roughly. They should also see that the wool was taken off closely, without too many second cuts being made, and that the sheep were not turned out with too many ridges left on them. Farmers could do more classing of their wool. It would pay to keep the hogget wool separate from wool from older sheep, as a hogget was likely to produce a fleece of longer staple than an old sheep.

Dipping.—Dipping could be done immediately after the sheep were shorn. It would be more effective if done while the sheep were clean and the dip mixture would act as a disinfectant for the cuts and wounds the sheep had received during shearing. After dipping they should be turned into a fallow paddock. Dust would collect on the tips of the wool that was left, and would act as a little protection for the skin against the sun and the cold weather. Sheep which were dipped a month of two after shearing did not receive the full benefit of the dipping mixture. The writer had shorn lambs carrying ½in. wool which had been dipped about a fortnight before being shorn. The dipping mixture had reached the skin all over the body, but from the top of the head half way down the back of the neck a strip of skin was left which had not been touched by the dip. Care should be taken when dipping to see that that part of the sheep was soaked thoroughly. It could not be done thoroughly unless each sheep was pushed under and kept under for a few seconds. If that were done about three times it should result in the sheep being dipped correctly. Sheep should never be put through the dip immediately after travelling a long distance. They should stand in a yard for an hour or two; otherwise the result might be two or more dead sheep, because they were likely to swallow some of the liquid if they went through the dip while panting. An S hook was very useful, both for pushing the sheep under and for hooking a sheep under the neck in case of drowning. If sheep were dipped immediately after shearing, eight or nine thousand could be put through before the dip required renewing, while if sheep were left a month or longer after shearing, not more than four or five thousand could be dipped before the dipping mixture was changed. A number of farmers had not dipped their sheep of recent years. Such neglect was unfair to their neighbours who dipped every year to free their sheep from lice and tick.

Crutching and Eye-clipping.—Crutching should be done at least three times per year if done with blades; if machines were used twice a year would be sufficient. It was the best and only remedy to overcome the blowfly pest. If crutching were done before any sheep were fly-blown, the blowfly would not be encouraged. Farmers who let their sheep go as long as possible to save the expense of crutching made a big mistake. Crutching at the rate of £1 per 100 would be cheap (although only about 10s. per 100 was usually charged for machine crutching), as one only had to lose two sheep or lambs out of a hundred by blowfly strike to equal the cost of crutching. As soon as an owner found one sheep struck by flies he should lose no time in getting them crutched. Even the one sheep already struck might mean a greater loss to the owner than he anticipated. Ofter a sheep which had been badly struck by maggots grew a fleece with a break in the wool. One such fleece found among other good wool might cause the whole bale to be condemned as far as value was concerned. All sheep inclined to be wool-blind should be clipped aroung the eyes just before the barley grass dried off. Otherwise barley grass seeds would be picked up and work their way into the sheeps' eyes.

Lambing.—All rams should be taken out of the flock a month of two before the first lamb appeared. It did not pay to keep the rams in the flock all the year round. One well-grown lamb was worth more than two "poddies," and the mother would be given a better chance to grow a more valuable fleece. Where rams were left in the flock all the year round, it often happened that the first lamb still sucked its mother when the second one arrived, with the result that the second lamb had a very poor chance of survival. The same applied to the old sheep. Just before lambing it was necessary, especially with young sheep, to shear them around the eyes, so that they could see around them better when they dropped their lambs. It was noticeable that when a wool-blind sheep dropped its lamb crows soon appeared on the scene. One crow would draw the attention of the sheep and the others would attack the lamb. Many lambs were lost in that way, crows doing more harm than foxes at lambing time.

Starving Sheep.—A good many sheep owners tried to run more sheep than they could provide feed for. Great losses occurred by starving a flock of sheep. It was far better to have a little left in the paddocks than to see sheep hunting for feed. A sheep could lose in one week as much condition as it would take a month or even longer to regain. Not only did a sheep lose condition, but it also checked the growth of the wool. Any sheepowner who had kept sheep at a loss should aim at keeping less sheep, keep them in good condition, produce good wool, and rear a profitable lamb.



More acres to the gallon with this
BRITISH Tractor Fuel

For straight-out performance there's no better tractor fuel than "C.O.R" Power Kerosene. It is British-Australian, and blended to give power, efficiency and economy in full measure. Try it... your tractor will show the difference.

Available in convenient 24-gallon drums.

RUGGING SHEEP.

At a meeting of the Green Patch Branch on 5th March, Mr. D. Cash gave a report on his experiments in rugging sheep. He was using 20 ewes and 20 wethers (all 4 tooth), as well as a similar number unrugged. He stated that in rough limestone or mallee country rugs would be useless as it would not be possible to keep the rugs on the sheep. Even in an open paddock he found that constant oversight of the sheep was necessary in order to keep the rugs in place. Where conditions were such that they could not be examined daily he considered that rugging would not be practicable. The fitting of the rugs took a great deal of time. They had to be well fitted or the sheep would soon get rid of them, even in an open paddock. The rugs he used were bought rugs, and he considered that they should be made more adjustable. He could see that several more fittings would be necessary as the wool grew. Some sheep took to the rugs quietly, while others did their utmost to get rid of them.

CARE AND MANAGEMENT OF CHAFFCUTTERS.

The following paper was read by Mr. Thos. Rodda at a meeting of the Boor's Plains Branch held on 5th March:—"Chaffcutters, like all machinery, require to be set on a solid foundation in the earth to ensure absolute rigidity and steady working. A machine set on an unsound foundation will not run freely and will soon commence to work and vibrate in the joints of the framework and undue wear will take place in all the bearings and spindles, causing heavy driving. Set on a good foundation and with reasonable care and management, a chaffcutter will work smoothly and evenly, with the minimum amount of driving power and give good and lasting service.

Setting.—If the machine is to be set in the open near the stack, the place should first be levelled off. Four holes should be sunk corresponding with the legs of the machine. A stump leg of hardwood (preferably jarrah) should be bolted on the lower end of each leg of the chaffcutter. The stumps should be 4in. x 4in. cut 20in. long. About 4½in. at one end should be halved so that the end of the cutter leg will stand on the shoulder. It should then be bolted to the leg with a ½in. bolt. The machine should then be set in the exact position. Care should be taken to level correctly the knife wheel spindle in one direction and the bevel gear spindle in the other. For small machines it is sufficient to ram the earth well around the stumps. For large machines concrete should be used. Care must be taken to see that the pulley is in correct alignment with driving pulley. The best belt length is approximately 12ft. from centre to centre of pulley spindles. The width of belt, working speed, driving power required and cutting capacity per hour are as follows:—A No. 3, running at 350 to 400 revolutions per minute, needs approximately 4 B.H.P. with a 3½in. belt, cutting approximately 15cwt. per hour. No. 4, the most general cutter, running at 400 to 500 revolutions per minute, needs 7 B.H.P. with a 4in. to 4½in. belt, cutting in the vicinity of 2 tons per hour. If it is desired to use screens or an extra long elevator, the B.H.P. may need to be increased slightly.

Feeding and Cutting.—In order to get the best results from a cutter it is essential to feed it correctly. A good even sample of chaff can only be obtained by keeping the mouth always continuously full. When placing sheaves in the feed trough they should be elongated, and the next sheaf overlapped so as to form a continuous flow of hay of uniform thickness into the mouth. The sheaves are best fed with heads forward. Cutting chaff from looose hay (not in sheaves) requires more activity and care by the feeder. The hay must be straightened out as much as possible to get an even thickness of flow into the mouth. It is a wise plan to practice keeping the fingers of the left hand as much as possible across the feed trough when feeding. If this is made a practise there is no danger of the fingers being caught under the roller and drawn into contact with the feed rollers.

During summer months the hay becomes very brittle on hot days. If cut while in this condition it will break up to powder and become very poor horse feed. This can be improved by sprinkling with water, either through a hose with a fine rose, or if water is not laid on, with a garden watering can, and should always be done several hours before cutting. Care must be taken not to apply excessive moisture, or the chaff may mould and become useless as horse feed. There should be just sufficient moisture to give the hay a feeling of toughness. Wet hay often will wind around the rollers, and if it is allowed to continue for a time it will cause heavy driving, with always a danger of bursting the mouth. There is little need to stress the point that chaff cut under these conditions cannot be kept.

Knives.—The chaffcutter cannot do satisfactory work if the knives are neglected. They should always be kept sharp and in correct adjustment. They will gradually leave contact with the steels on the mouth. When this is evident they should be re-set by means of the set-screws. This should be carefully done, a quarter of a turn of the set-screw making the difference between correct and incorrect setting. When correctly set they should have a slight even rub on the mouth steels from end to end, like a good pair of sheep shears or scissors. When the outer edges of the mouth steels become worn unevenly they should be taken off and reversed. The steels on the side cheeks are held by set-screws and can be reversed without disturbing any other parts. The bottom steel is riveted to the comb, which is held in the machine by two bolts. To reverse this the comb must be taken out, the rivets taken out, the steel reversed, and re-riveted. When replacing the comb, care should be taken to ensure that it fits snugly into its place and that the bolts are tightened evenly. The combs should be kept adjusted well in mesh with the feed rollers in order to prevent hay from winding around the rollers. Remember that blunt knives will use much extra power, and a bad sample of chaff will be the result. When knives are being sharpened with the file, the edge should be kept as long as possible or as near the length of the maker's edge as it can be kept. If the edge becomes very short the knives should be taken off and ground back to a longer edge.

Lubrication.—Efficient lubrication is the first essential for the successful working of any machine which has revolving spindles. A chaffcutter, when working, is always surrounded by a cloud of fine dust. This dust is always entering the bearing in small quantities. If this is left to continue for long periods without lubrication, the lubrication in the bearings will be dried out and heating and cutting will set up. The chaffcutter should have frequent applications of good lubricating oil. Special attention should be given to the reversing clutch bevel pinion on the knife wheel spindle. This pinion runs at very high speed, as it revolves in the opposite direction to the knife wheel. If allowed to run dry it will often cause a loud screaming sound. A second essential is to use a good quality oil.

General.—Chaffcutters generally are well made and of good material. If the machine is left out in the open where the rains of winter and the hot sun of summer have full play on it it will deteriorate much faster than if it is kept under a rain and sun-proof covering or roof. The effect of exposure will do more harm than the actual work on the average small farm. All bolts, nuts, and set-screws should be kept in place and kept tight, and set-collars kept in correct adjustment when wear takes place. If a bolt is accidentally broken another of correct length and diameter should be procured as soon as possible. Driving belts should not be worked too tight. There should be just sufficient tension to give the necessary adhesion on the pulley to drive the cutter. Excessive tension will only add to the driving power needed, and cause extra wear. If the foregoing hints and instructions are observed and the machine given reasonable care and management by the operator, the chaffcutter will not fail to give its owner many years of good and profitable service.

CONSTRUCTING FOOTPATHS AROUND THE FARM.

At a meeting of the Millicent Branch held on 28th February, the Secretary (Mr. L. C. Hutcheson) read the following paper:—How often is it when one is visiting farm houses the first introduction is stumbling over loose stones and stepping into mud-holes when walking along so-called footpaths? For one's own personal convenience, is it not better to have a decent entrance or a well constructed footpath? The first thing to take into consideration when making footpaths is to see that they are made high enough above the natural surface ground. The centre should be 9in. above the ground. This may sound extraordinary, but footpaths have a bad habit of sinking, and the surrounding gardens and lawns always come up sufficiently high. Nothing is worse than to have a low lying path on which water lies. The kinds of paths are many and varied and, of course, financial circumstances play a very big part in the style of path to be constructed. Perhaps the best is concrete, laid down in sections. This may be expensive, but it must be remembered the first cost is the only cost, and one which would turn out cheaper in the long run. Where one cannot afford the outlay of concrete, attention should be given to something of a cheaper method, but on no account should efficiency be sacrificed for the sake of a few shillings. There are several bitumen-like preparations on the market, and I am going to deal with the colassed footpath. Colas is an emulsion of bitumen, a patented process that can be applied cold. It is a chocolate coloured liquid of a consistency slightly heavier than water. It is manufactured from the highest grade bitumen and may be applied to either a damp or dry surface. The only tools necessary are a broom, or preferably a rubber squeegee, a watering can with a colas baffle, a shovel and a wheelbarrow. A roller is also desirable. In general, the application consists of pouring colas on the surface, drawing this out to a thin film with the squeegee and covering with screenings or clean coarse sand, and then rolling. This gives an excellent bitumen surface for the footpath. A squeegee can easily be made from any strip of rubber or leather held between two boards 18in. long, with a handle fitted. First of all, the foundation is to made. Edging of the path is most essential. Boards rot and will not last, so I recommend either stone (sawn white stone is very good) or concrete slabs. If edging is not done, no footpath will hold good, and it would only be a waste of time, energy, and money in putting down such a thing. Practically any gravel is good. The common drain bank gravel works down very well, but if limestone gravel is used a thick gritty surface must be obtained on the top. To do this two coatings of colas with ¼in. toppings or screenings must be used. When the gravel is laid down it should be dumped or rolled to obtain a smooth and solid surface. It should then be dumped and the colas applied with a squeegee, and to which the screenings should be spread quickly, and then rolled. Screenings must be put on before the colas turns black. Sweep off all loose screenings before applying the second coat. This can be done almost immediately. A third coat, this time using coarse sand, can then be applied, Altogether a surface of between ¼in. to ⅜in. of bitumen would be obtained. If any low-lying places are noticed, they can be filled up with an extra coat of screenings before the final coat of coarse sand. There is no doubt that a path made in this manner would last for many years. One need not be afraid to walk on such a path immediately it is laid, as it will not do any harm; in fact the more traffic the better the path. A brief discussion on the utilisation of lands at present covered with bracken fern followed, and the meeting closed.

QUESTION BOX.

The Sutherlands Branch meeting held on 14th March took the form of a "Question Box." Fifteen members and visitors were present, and the following questions were dealt with:—*Question:* Most profitable concentrates for milch cows? *Reply:* About 1lb. oats and bran fed with cocky chaff. *Question:* Should cows receive stable feed all the year? *Reply:* Not if there is feed in the paddocks. *Question:* Would dehorning cows be advantageous? *Reply:* It would be best to dehorn. If possible it should be done while still a calf by rubbing caustic soda on the tips of the growing horns. *Question:* Is the rigid-tyne combine to be preferred to the spring-tyne implement? *Reply:* Several members preferred the spring-tyne implement. *Question:* Would the bones of animals that have died from poison be injurious to cows? *Reply:* Bones of animals which have died from strychnine poisoning would not harm cows. *Question:* In feeding crushed wheat to horses, should one wet the chaff or the crushed wheat? *Reply:* When feeding crushed wheat, damp the chaff, but if feeding oats leave it dry. *Question:* Would barley be profitable as a rotation crop? *Reply:* Barley could be grown in the district in average years with quite good results. *Question:* Most suitable variety of oats, both from grazing and grain points of view? *Reply:* Algerian oats best for grain, and Lachlan best for feed. *Question:* Which post will stand the longest, white or red mallee? *Reply:* White mallee considered the best, but it depended on the age and quality of the wood. *Question:* Best way to destroy weevil in a barn? *Reply:* Spray with copper carbonate. *Question:* Is barley better than oats as a livestock food? *Reply:* After some discussion an extract was read from the bulletin "Popular Farming Fallacies," by W. J. Spafford. *Question:* Best variety of barley for the district? *Reply:* Cape barley was preferred. *Question:* Treatment for sitting hens infested with lice? *Reply:* One member suggested "Insectibane." *Question:* Most suitable breed of cow? *Reply:* Friesian or Shorthorn. *Question:* Cure for roup? *Reply:* 2 drops eucalyptus, 1 drop kerosene, 1 teaspoon olive oil.

CARE OF SMALL ARTICLES.

In the course of a paper read at a meeting of the McLaren Flat Branch on 5th March, Mr. W. Kyloh stated that tools were often badly neglected, and should receive more attention. The hand saw should be kept from becoming rusty by frequent rubbings with grease, vaseline or oil. The handle should receive a coat of boiled oil occasionally. Bits should be kept apart from other steel articles, otherwise the edges and points became burrel, and would not bore a clean hole. If they were well greased or oiled before being put away they would last much longer. The most common files used on a block were 10in., 12in. flat, and a 3-cornered file. The useful life of a file was usually short, but it could be considerably lengthened by keeping it from coming into contact with other steel articles, from developing rust, and by providing it with a handle. *Pumps and Wells.*—All common pumps had 2 valves, one to hold the water and one to lift the water, commonly known as suction and plunger valves respectively. On most pumps there was also a foot valve. Though a foot valve was not absolutely necessary to a pump, it was very useful, as it served two useful purposes. It prevented rubbish and small pieces of water-logged wood from getting into the pump and jamming the valves, and it assisted the suction valve in keeping the pump full of water. Good quality harness leather should be used to renew pump washers. The leather should be of even thickness, or difficulty would be experienced in making the pump airtight. In replacing the piping, thick paint or white lead should be used on the joints to prevent them from rusting. The job could then be more easily done next time.

POTATO GROWING.

At a meeting of the Ironbank Branch, held on 4th March, Mr. E. W. Mattner, of the Balhannah Branch, spoke on potato growing. He said that the ideal plot for growing potatoes was a Subterranean clover paddock which had been heavily stocked, and was well covered with animal droppings, that being the best fertilizer he knew. Any old straw or rubbish could be ploughed in also. The first ploughing should be done in July, as deeply as possible, care being taken not to bring the clay to the surface. No harrowing should be done at that stage, the plot being left rough until September, or even later if conditions were very wet. One should then cross-plough again deeply, and then cultivate every week or so, until planting. The more the ground was cultivated the better the crop would be. Just before planting the plot should be ploughed again a third time, ploughing the same way as the rows of potatoes would be planted. The ground should be cultivated down to a fine tilth, and should then be ready for planting. Planting should commence about the middle of November, and could be continued until Christmas, or even later. Where water was available for irrigation the sets should be placed 1ft. 6in. apart, and the rows 2ft. apart. For dry ground the distance should be greater—about 2ft. by 2ft. 8in. After planting the ground should be rolled and harrowed at once. The speaker had used all kinds of artificial manure, the best being a mixture of super, 4 or 6 parts, and sulphate of ammonia, 1 part. To obtain the best results this should be sown directly on the seed in the rows at the rate of 10 or 12cwts. to the acre. Carefully selected seed from the best plants only should be used, the large potatoes being cut not too small, the cut seed planted early, and the small tubers kept for later planting. When the seed was cut it should be placed into wet bags, and any seed left over from the day's planting should be immersed for a few seconds in water. A specially-made bag to hang on the hip, supported with shoulder straps, was considered the best container to use while planting. Irrigation was carried out by allowing water to run gently between the rows. After each watering the ground should be well cultivated, care being taken not to disturb the roots of growing plants. For dry ground planting could be done up to the middle of January, Carmen being the best variety where no water was available.

THE FLOWER GARDEN.

Mr. L. H. Noll read the following paper at the March meeting of the Nelshaby Branch, when 15 members and a number of visitors were present:—"The flower garden is a sideline, and, at the same time, a beautifier of the home. I am about the only one in this district who has it as a sideline. I have found it a great success—better than growing wheat. Of course, it is necessary to consider climatic conditions, water facilities, and the right kind of flowers to grow, as a lot of flowers that do well further south would do no good here. We have to go in for the more hardy sorts—something the wind cannot damage. Of course, there are very few flowers that can stand the east winds. Brush fences are fairly successful, but must not be too far apart. The sweet peas are too dainty for this district—that is, to grow them the right way. For winter, the best flowers to put in are stocks, carnations, bulbs of practically any description, the ranunculus being one of my favourites; also, anemones, Iceland poppies, and antirrhinums are also good to put in. So far I have used very little manure in the garden, and that mainly cow manure. I also use super, as it keeps the garden cleaner. Quite a lot of ashes and lime are used on the beds before digging. In summer one must have plenty of water. Dahlias, zinnias, asters, and marigolds are grown with success. Plenty of others can be grown, but one does not want too many kinds. It is better to make a success of a few. The above varieties are hardy, and have long stems, which they must have to be suitable to sell. In summer the plants must be grown in trenches, and the seeds must be sown in place, where possible, to avoid transplanting. A light mulch is needed to protect them from the hot sun, and it also keeps the moisture, thus helping to cut down the water bill. I was told that asters must be grown in a shady place. I grew mine in the open, and they could not be better. I grew the Giant Orego variety. Zinnias are a wonderful summer flower. The hotter the day—providing they have enough water—the better they bloom, and they have so many different shades. The more you cut them the more they bloom. This applies to most kinds of flowers. Many people, if they have nice flowers, are afraid to pick them, which is quite a mistake. If you want them to continue flowering you must pick off all the old flowers every week. Gladioli are beautiful flowers to grow. They receive the same treatment as other flowers, but you only get two blooms a year from them. Of course, to sell them is another matter, or they would not pay. On the other hand, the bulbs only need to be put about 3in. apart, so one can get quite a lot in a bed. Dahlias must have the stem burnt; this applies also to poppies. Dahlias are not a flower for this district at all, but, because of their beauty, I cannot resist them. They cannot stand the least bit of wind, the flowers being easily spoiled. Unless one has an extra shelter for them, also a bountiful water supply, one can only expect a reasonable success with them. They require plenty of mulch. I put fresh plants in every year, as they do best. Antirrhinums will stand two years, as will stocks, but it is safer to plant them fresh every year. Bulbs I take up every year and divide. Never plant the same flowers in the same place two years following. By so arranging that when one flower stops blooming you have the other starting one never needs to be without blooms for the whole twelve months of the year.

SUMMARY OF REPORTS RECEIVED.

Branch.	Date of Meeting.	Attendance.	Subject.	Secretary.
		SOUTH-EAST DISTRICT.

WOMEN'S BRANCHES.

CONFERENCE AT OWEN.

Mrs. Wilson, of the Wasleys Branch, presided over the Conference of Lower North Women's Branches, which was held at Owen on 27th February. Miss E. Campbell, of the Education Department, gave an address, "Household Hints," and the following papers were read and discussed:—

GOOD READING.

[Mrs. A. Telfer, Clare.]

There is nothing, perhaps, that is a more universal boon to the human race than the ability to read. From the time we first discover the magic of building words from apparently meaningless letters there opens up a vista of joy, beauty, and knowledge that widens and deepens as time goes on. Always some new pleasure unfolds, some new truth is displayed, and through the medium of the printed page knowledge of the whole world is given us, and also the thoughts and experiences, the joys and sorrows of other human beings.

When books were painstakingly written by hand, and skill in the arts of writing and reading was confined to very few—and those few the priests and monks of the times—nothing was written that did not have the twofold purpose—to educate and elevate. The early writings consisted of translations of the Scriptures and of the lives of saints and, of course, were not for the ordinary people to handle, even had they so wished. In these times, when practically every one is able to read—and quite too many, we are convinced, feel that they can write—books of all kinds flood the market, not to mention newspapers, magazines, and periodicals innumerable. All that are published find readers somewhere.

The question is often asked, "Why do people read?" and various reasons are given: Some read to gain knowledge and new avenues of thought, and some as a substitute for thought.

When we are young we read because of a desire for knowledge, if we are ambitious, or from a thirst for romance and adventure. The quieter our environment the more eager the quest for the romantic and adventurous in fiction. As we grow older, and the cares of life throng around us—though life may not be a series of thrills such as the cinema and some books would have us believe—we find our tastes becoming quieter, and something restful is often welcomed, especially for the busy mother whose time for reading is limited and often combined with the necessary moments of rest.

For whatever reasons we read—and most of us, if not all, read chiefly because we enjoy it—we should not be satisfied with anything but the best. That, you say, is all very well, but how do you know what a book is until you have read it? This is where the benefit of our circulating libraries comes in. We get such a variety here at such a comparatively trifling cost. We have the opportunity of reading the most modern, as well as those not so new, and having perused or skipped through them as fancy dictates we can decide whether we will have them on our bookshelves to become our friends—for books are friends in a very real sense.

Some of the best books for young folk—and we need to be careful in guiding the tastes of our children in this—in addition to selections from the best poets, suitable travel books and biographies are by Australian authors. Where would you find a better series than the "Billabong Books" by Mary Grant Bruce, while Ethel Turner stands alone in her "Seven Little Australians" and its sequel, "Flower of the Pine." Lillian Pyke, Lillian Turner, and Jean Curlewis also delight the young folk and their elders. The books by Edward Ellis still fascinate boys and girls, and the "Anne" books by L. M. Montgomery delight girls and their elder sisters and mothers as well. Then who has not revelled in "Alice in Wonderland," "Water Babies," the "Just So" stories, and A. A. Milne's poems and stories.

In the adult section, except for those books by Ion Idriess, "Flynn of the Inland," "Lassiter's Last Ride," and a few other by the same author, also two or three written about the convict days, notably "The Term of His Natural Life" and "Pageant"—the last-named has a Tasmanian setting and is by Lancaster—"Camel Pads," and Myrtle Rose White's "No Roads Go By," I do not place the books by Australian authors that I have read in the category of "Good Reading." The writers whose works have stood the test of time like Dickens, Hardy, Charlotte Bronte, Jane Austin, and Scott in parts are still good, and worthy of a place on our book shelves.

The modern books comprise so much variety, and those that are good are very good. In fiction, to mention a few, "The Good Companions" by Priestley, "Jim Redlake," "My Brother Jonathan," "The Portrait of Claire," "White Ladies" by Frances Brett Young, "Carolyn of Scarpa" by Flora Klickman, those two beautiful and wholesome books by Bess S. Aldrith, "A Lantern in Her Hand" and "A White Bird Flying, "Precious Barneby" by Mary Webb.

Then books of travel! It is the fashion nowadays to go by air, car, or caravan, to walk or cycle over or around the world, or into remote parts of it, and come home and tell about it; and how interestingly reads the telling! So if one would travel by proxy—and most of us must be content with that—let us go over Africa, then to Europe, Asia, and back to Australia with Richard Haliburton in his "Flying Carpet"; round and about Australia with Dr. Thomas Wood in "Cobbers"; go by steamer, train and car into the beckoning horizons of China, Japan, and Russia with Sir Wedgewood and Margaret Benn; or travel with H. V. Morton trying to see all he sees in those out-of-the-way spots of beauty and tradition, history and romance throughout the British Isles and Palestine, and so one could go on.

Good reading is so diverse in its nature and purpose that one can only touch a phase or so, and the outer fringe at that. As with a beautiful flower or landscape, we can take and enjoy all that there is in good books of nobility, grandeur, beauty, and still leave it all for the enjoyment of others.

PREPARING POULTRY FOR THE TABLE.

[Mrs. E. CATFORD, Clare.]

Poultry of some kind is an appetising dish at all times, and those who wish to secure the best will find it necessary to know what points there are in selecting good, tender birds for their use, and how to treat it in preparation for cooking. It is neither as difficult nor as disagreeable as one thinks if done properly.

Poultry for roasting should be young and tender, but for boiling and stewing it may be more mature. To ascertain if the birds are young the legs and feet should be pliable, and the end of the breast-bone easily bent. A fowl is usually called a chicken until it is about 9 months old. Turkeys when young have white, smooth legs, and the skin of the body is white and clear. Old turkeys have very red legs, and the flesh is hard and tough. Young geese and ducks have very yellow and pliable feet and legs, the flesh is very soft and smooth to touch, and the under-bill is easily broken. If they are old birds the skin of the flesh is hard and dry.

The feathers are easy to pluck if, as soon as the birds are killed, they are dipped up and down into a bucket three parts full of boiling water for a few minutes—geese and ducks require a little longer time—then take the bird out of the water and wrap it in a cloth or bag to steam for a few minutes. When it is plucked clean and quite free from pin-feathers singe off the down.

To draw the bird first cut off the legs, then the neck (if desired), and cut a slit in the skin and remove the wind-pipe and crop with the fingers and pull it out whole, taking care not to break it. Now make a slit crossways, just under the tail, being careful not to interfere with the intestines. Insert the fingers and grasp the gizzard and draw everything out, being careful not to break the gall-bladder; if this should happen wash the bird out with warm water immediately and dry thoroughly. Save the giblets, as these are delicious for soup or gravy and served in many other ways.

Wash the bird and it is ready to be stuffed, trussed, and tied for roasting. Place the bird breast downwards into the baking dish for a while, and then turn it on its back later on when the juices have run into the breast. This prevents dryness of the flesh when it is cooked.

If a turkey or any large bird is too big for the oven the bony frame of the back can be removed easily with a sharp knife by making a slit in the skin from the neck to the tail; then cut the flesh and scrape it from the bone to the ribs on either side, breaking through the wing and leg bones, leaving these bones intact. Break through the ribs and remove the large backbone, but leave the breastbone, wing, and leg bones in the bird.

When the bony frame is removed from the back of large birds, and then well filled with seasoning or force-meat and sewn up again to resume the shape and size of an unboned bird, it makes it possible to cook a large bird comfortably, and also to carve and serve more easily.

When the birds are prepared cover with greaseproof paper, bake slowly to preserve the juices, and baste frequently with a good supply of hot dripping. A sprinkling of flour and salt helps to brown the birds nicely, and removing the greaseproof paper about half an hour before serving also helps the browning.

The time for cooking a large turkey is about 2½ to 3½ hours slow cooking, and geese and ducks require about 1½ to 2½ hours, according to size and age of the birds.

Old fowls, when boiled slowly, are made tender by the moist and slow method of cooking, also if a little vinegar is rubbed over the fowl it will help to make the flesh tender. There are several ways of dealing with old birds to make them appetising. An "old hen" can no longer be despised if dished up in some of the following ways:—(1) A very nice dish can be made by boiling an old fowl until it is tender, then take out all the bones, and when cold mince it up with some ham or bacon, season with thyme, pepper, and salt, and mix together with a beaten egg. Fry in breadcrumbs until a nice brown, and serve with gravy as for rissoles. Boil the fowl until tender, then put it into a baking dish with dripping, and serve with baked batter pudding, vegetables, and gravy. Gently simmer a fowl in a saucepan with a sliced onion, a pint of water, and some dripping. When it is cooked allow to cool, then cut off slices of meat and dip them in flour and place them in a piedish in layers with a few slices of ham or bacon. Add pepper and salt to taste, and sprinkle some finely-chopped parsley over each layer. When the dish is full pour over it some good stock or the liquor in which the fowl was boiled. Cover with some short pastry, and bake for ½ hour. Serve hot with vegetables.

To make stuffing for geese and ducks:—Boil some onions until they are tender, then strain and mince them with a fork on a dish. Add some breadcrumbs, pepper and salt to taste, and a few crushed sage leaves, a sprinkle of thyme, and a dessertspoonful of butter or dripping. Mix all together and stuff the breast and body, sewing the opening so that the seasoning will keep intact while it is cooking.

For turkeys and fowls the seasoning is made with breadcrumbs, thyme, salt and pepper to taste, and a grated lemon; mix together with a beaten egg. To stuff the breast of a turkey fill it with forcemeat, and sew the slit in the skin. When serving the turkey the sliced pieces of breast are very helpful to make this supply go further, especially at a large gathering when more is needed. Boiled ham or fried bacon should be served with all poultry.

There are several ways of using up cold poultry that is left over, and the following are some recipes that may be very helpful when one has got some pieces of meat on hand.

LEFT-OVER POULTRY PIE.

Remove all the bones and cut up the pieces of meat and scraps of seasoning. Line a baking dish with pastry or batter, and put the pieces into the dish with a sliced onion. Pepper and salt to taste, and a spoonful of Marmite or stock and a little chopped parsley. Sprinkle some breadcrumbs over the top, and add a few small pieces of bacon. Put into the oven, and bake until a nice brown. Serve hot with fried tomatoes or other vegetables.

JELLIED POULTRY.

Cut up pieces of cold cooked poultry, and put into a basin or mould. Mix separately a dessertspoonful of Marmite or good gravy with some boiling water, add some dissolved gelatine, and season to taste. Stir well together, and pour it over the meat, then place it in a cool place to set. Turn it out on to a plate, serve with slices of cold bacon or ham, and garnish with parsley. This is also a delicious filling for sandwiches.

KNITTING.

[Miss K. M. KOCH, Clare.]

Knitting is one of the most fascinating pastimes for winter evenings, and many useful garments as well as toys and novelties can be made. For summer jumpers, underwear, and infants' wear 2-ply wool is most suitable, but for winter jumpers, cardigans, scarves, cosies, cushion covers, &c., 3 or 4-ply is required. Odd scraps of left-over wool may be made into gay cushion covers for the breakfast room or verandah.

There are only two stitches used in knitting—plain and purl—and it is just a matter of how they are put on the needles that makes a pattern. When these two stitches can be made, it should be possible to follow any directions and be able to accomplish any garment, no matter how intricate the pattern. Stocking stitch is the most commonly used—this being obtained by knitting one row and purling the next. For summer jumpers, a more open pattern is essential, and many pretty lacy designs may be found in some of the knitting books. Fancy ribs have now become very popular for winter cardigans. For men's and boy's pullovers and cardigans—both cream and coloured—nothing is more popular than the cable stitch.

HINTS TO KNITTERS.

Wool should never be wound into a hard ball; this stretches it and makes it thin and poor. Wind loosely over three or four fingers and the wool retain its softness.

In commencing the first row always knit into the back of the stitch, and a firm edge will result.

When starting a garment always cast on a few stitches and knit three or four rows to see what tension you knit. If you do more stitches to the inch than the pattern indicates less will be required for the garment.

To keep the work smooth and even be careful to knit the same tension all the time.

Do not leave the work in the middle of a row or poke the needles through the knitting; the latter will make holes.

When starting a row always slip the first stitch.

If using two colours do not draw the wool on the back too tightly.

To keep white knitting clean rub the hands occasionally with talc.

When working a large pattern with several colours it is better to work each section of the pattern with a separate small ball of wool to avoid carrying the wool across the back of the work.

A great help to indicate where stitches have been decreased is to knit in a coloured thread at the decreasing row, which can be pulled out easily.

Before making up a garment press all pieces thoroughly with a damp cloth and a hot iron.

When using different wools, to prevent them from becoming knotted, place in a cardboard box and pierce as many holes in the lid as there are balls of wool, and thread through the holes.

When buying wool for a garment always buy sufficient to finish it, or there may be some difficulty in obtaining the same shade again.

To join wool neatly darn one end into the other.

When buying knitting needles choose a contrast colour to the wool that is being used as it is not so trying to the eyes.

CONFERENCE OF WOMEN'S BRANCHES AT BEETALOO VALLEY.

Mrs. P. Curtin occupied the chair at the Conference of Mid-North Women's Branches of the Agricultural Bureau, held at Beetaloo Valley on 12th March. Delegates and visitors to the number of over 100 were present from Belalie, Wirrabara, Narridy, Gladstone, Nelshaby, Georgetown, and Beetaloo Valley.

Addresses were delivered by Miss E. Campbell (Education Department), and Messrs. H. B. Barlow and C. F. Anderson, of the Department of Agriculture.

The following papers were read and discussed:—

CITRUS FRUITS AND THEIR USES.

[Mrs. D. Brooks, Belalie.]

Of all articles of diet, probably fruit has the most important claim to general use, with its abundance of those vitamins which are most essential to human growth and well-being. Of all fruits, possibly those belonging to the group known as citrus fruits would be considered the most important and indispensable. To this group belong Oranges, Grape-fruit (described in the dictionary as a form of orange that grows in clusters), and also known as the Shaddock, the Bitter Orange, the Seville and Poorman's varieties, Citrons, Lemons, and Limes. Oranges have been described as "stored sunlight," and when one pictures a tree in full bearing one can quite appreciate the description. They are said "to supply all valuable minerals to build strong teeth and bones, rich blood, nerve tissue, and help to regulate the body. They stimulate the appetite and aid digestion."

In a country like ours, the natural home of such fruit, it would be a sin if the claims of these wonderful gifts of Nature were ignored or overlooked.

The first form of diet prescribed as additional to the natural feeding of an infant is the juice of an orange, and as the child advances to more mature development, not only do the oranges still perform a great function in nourishing and regulating his body, but they should be given in ever increasing proportions.

Even as the saying, "An apple a day keeps the doctor away" has a deal of truth in it, so we might apply the statement to oranges with equal force and suitability.

The lemon, too, in its raw state has great medicinal as well as appetising value. It is being increasingly used for the wonderful properties of its juice, and to some palates is even welcome as a fruit.

Both oranges and lemons are greatly appreciated when used in the making of cooling summer drinks. The lime, too, is used commercially for lime juice.

The grape-fruit is a recognised breakfast dish, being a particularly useful fruit to open a light meal. The other varieties of citrus fruits are mainly used in jams and preserves, and may be dealt with as a group rather than singly.

MARMALADES AND SWEET CITRUS JAMS.

Make sure that all the fruit is very fresh and not over-ripe. Always soak and cook the fruit until the skin is completely tender before adding the sugar and remember that the sugar, when added, immediately hardens the fruit. Boil all jams steadily and evenly, and bottle while hot. Place in clean dry bottles, and keep, when sealed, in a cool place.

Sweet orange fruit—especially when kept a while before using—is a welcome addition to the jam supply, being palatable even to those who do not care for marmalades. All forms of citrus fruit may be used in the making of marmalades, and if the fruit be good, the method of making seems to be capable of wide variations, both as regards time and quantities of sugar and water to be added.

The grated rinds of the different fruits may all be used with good effect as flavourings, particularly in cakes and puddings.

THE LEMON.

The lemon clears the throat, sweetens the breath, keeps the gums in a healthy condition, and is excellent for internal disorders, such as biliousness. The lemon is also a valuable toilet requisite, and if the hands need to be cleansed of stains, a little lemon juice will do the work. Brass and copperware take an added lustre when cleaned with lemon juice, while it will make still whiter a scoured table or sink. Lemon juice and milk applied freely to ink stains will completely remove those stains.

Another attractive use of these fruits is in removing the skins in halves and using them as baskets for jelly, fruit salads, or any other mixtures we wish to dispense. These are particularly suitable for a children's party.

There is a variety of ways in which slices of lemon may be used for garnishing purposes. A fish dish is improved both in appearance and flavour if slices of lemon are served with it. A slice of lemon floating on a finger bowl is a dainty as well as useful addition to that useful article. In many prepared drinks, too, slices of lemon add much both to flavour and attractiveness.

CANDIED PEEL.

Make a brine by boiling 1 pint of water and ¼ cup salt. Cut oranges, lemons, or citrons in halves. Pour the brine over them, and allow to soak for 3 days. Lift out, and drain on a wire drainer for about 24 hours. Make a syrup by boiling together for 10 minutes 1½lbs. sugar and 1½ pints water. Remove the pulp from the skins without bruising the skins. Place skins in the boiling syrup, and boil very gently for 20 minutes. Allow to stand in the syrup for 12 hours. Then repeat the same process every day for 3 days, soaking for 12 to 24 hours each time. Drain from the syrup, and allow to dry on a wire drainer. Sprinkle with sugar, and, when quite dry, pack in airtight jars.

GRAPEFRUIT JAM.

Cut the fruit into slices, not too thinly, and remove any seeds. Allow 3 pints of water to each large grapefruit. Pour this over the fruit, and allow to stand for 24 hours. Bring to the boil, and strain away the liquor, measuring it. Replace this with fresh hot water, and allow to stand for another 24 hours; then boil steadily, without stirring, until the fruit skin is quite soft. Weigh this, and allow 1lb. of sugar to each 1lb. of pulp and liquor. Make the sugar hot, and have the pulp boiling before putting together. Boil steadily until it will jelly. Bottle while hot, and seal when cold.

MANDARINE CONSERVE.

Use thin-skinned mandarines. Cut them in halves, and remove the seeds. To each quart of fruit allow 1 pint of water. Allow to stand again for 24 hours.

Weigh the pulp and liquid, and allow 1lb. of sugar to each 1lb. of pulp. Cook about 1 hour, or until syrup thickens. Bottle while hot and seal when cold. Keep for some time before using.

ORANGE RINGS.

Cut large ripe navel oranges into 4 thick rings. Cover them with a brine made by boiling ½ cup of salt and 1 quart of water. When quite cold pour over the fruit, and allow to soak for 48 hours. Drain, wash and cover with fresh unsalted water, and stand again for 48 hours. Drain and weigh the fruit. Cover with fresh, cold water in the preserving pan, and bring very gently to the boil. Cook without disturbing until the fruit is soft enough to rub the skin to a paste in the fingers. Lift rings out carefully with a wire lifter, taking care not to break them. Drain carefully. Make a syrup by boiling sugar and water in the proportion of 1lb. sugar to 1 pint of water in which the rings have been boiled. Allow this quantity to each 1lb. of the fruit. Bring the syrup to the boil. Lay the rings in it. Boil steadily without disturbing until it will jelly. Place the rings in wide-necked jars. Cover with the syrup. Seal when cold, and keep for some time before using.

ORANGE TART.

Puff pastry, 3 eggs, 3 oranges, 4ozs. sugar, 3ozs. butter. Beat the yolks, add the sugar, rind, and juice of oranges, melted butter, and then the beaten whites. Make the pastry. Line a deep plate or sandwich tin. Pour in the orange mixture. Bake in a hot oven until set and brown. Serve cold with cream or custard.

STEAMED ORANGE PUDDING.

2ozs. butter, 2ozs. sugar, 1 egg, rind and juice of 1 orange, 4ozs. S.R. flour. Cream the butter and sugar; add well-beaten eggs, then juice and rind, lastly well-sifted flour. Pour into a well-greased mould. Cover with greased paper. Place in a steamer. Steam for 1½ hours. Turn on to hot dish. Serve with orange sauce.

ORANGE SAUCE.

6 tablespoons orange juice, 6 tablespoons water, rind 1 orange, 1 tablespoon sugar, 1 heaped dessertspoon arrowroot, 1 teaspoon butter. Boil the water, juice, rind, sugar and butter; then pour on to blended arrowroot. Return to saucepan. Stir until it boils and thickens. Pour into hot sauceboat. Serve with steamed or boiled pudding.

ORANGE JELLY MOULD.

3 oranges, 3 gills stiff lemon jelly, ½ pint cream, 2 tablespoons sugar, ¾oz. gelatine, 1 gill milk. Divide the fruit into quarters after peeling and removing all pith. Line the bottom and sides of a plain mould with jelly. Lay in the orange quarters. Cover with jelly, and allow to set well. Whip the cream, add the remainder of jelly and the milk, in which the gelantine has been dissolved. When beginning to set, pour into the mould. Leave on ice until filling sets. Turn out on to glash dish. Garnish with whipped cream.

ORANGE FRITTERS.

Oranges, sugar, fritter batter, frying fat. Peel oranges, remove all pith, cut into slices. Lay on a plate and sprinkle with sugar. Make the batter in the usual way. Dip slices of orange in batter, then into boiling fat. Fry till a golden brown all over. Drain on white paper. Serve at once, sprinkled with sugar.

ORANGEADE.

4 oranges, 1 quart water, 2ozs. loaf-sugar. Wash the oranges and dry well. Rub sugar on the outside of the oranges until all the oil is extracted, then peel very thinly. Put half the rind, juice and sugar into a jug. Pour on boiling water. Cover and leave until cold. Strain at once. Chill, and serve.

ORANGE ICING.

8ozs. icing sugar, 2 tablespoons orange juice. Sift icing sugar into a basin, add juice, mixing to a thick consistency. Warm over the flame until thin enough to pour, but it must not boil. Pour over the cake. Leave until cold before cutting.

ORANGE CHEESE.

2 eggs, 8ozs. sugar, 4ozs. butter, rind and juice 4 oranges. Beat eggs well, add sugar, oranges and butter. Cook over boiling water until thick, stirring occasionally. Bottle at once. Use as filling for tarts or cakes.

ORANGE CURLERS.

8ozs. plain flour, ½ teaspoon baking powder, 3ozs. butter, 1 dessertspoon sugar, 2 tablespoons water, jam, frying fat. Sift the flour and baking powder, rub in butter, add sugar. Make into a dry dough with water. Roll out ¼in. thick, cut into rounds 2in. in diameter. Place ½ teaspoon jam on a round, wet edge, cover with another round. Press edges well together. Wet fry till a golden brown. Drain on paper. Sprinkle with sugar, and serve very hot.

SOME OF THE USES OF CITRUS FRUITS.

[Miss J. Halse, Beetaloo Valley.]

As the production of this particular kind of fruit has so increased in recent years, it is only natural that the various uses it may be put to increase accordingly, and as this district is recognised as one of the citrus-growing centres of the north, the subject should be of interest to the women at this Conference.

Oranges, the most popular of citrus fruits, are of very great value if eaten as fresh fruit. If this were done to a greater extent it would not only provide a better market for the quantity produced, but would be of very great benefit, for children especially.

The Navel orange is used mainly for eating in the raw state, but a very nice marmalade can be made from it also, as well as it being one of the main ingredients of the ever-popular fruit salad.

MARMALADE.

The most common marmalade for household use is made from either Poorman oranges or citrons. If the fruit is picked before it is fully coloured the marmalade is a lighter colour. Recipe for Poorman marmalade:—4lbs. oranges, 4 lemons, 16 cups water, 12lbs. sugar. Method:—Cut fruit very thinly, put in pan, and cover with water over night; boil 1 hour without sugar and 1 hour with sugar.

The Citron is more bitter than the Poorman orange, but it makes excellent marmalade. The most suitable recipe is:—Slice fruit very thinly, and remove all seeds. To every pound of sliced fruit add 2 quarts water (cold), and let stand for 24 hours. Then boil quickly for 2 hours, or until tender. Next day weigh, and to every 1lb. of fruit add 1lb. of sugar and boil until it will jelly. Seeds can be set in water, and jelly used from them.

LEMONS.

This fruit may be put to a multitude of uses, but is mainly used for drinks, especially in summer. Lemons are also a very valuable remedy for colds. The lemon has its other minor uses, such as juice for cleaning hands; a few drops in the rinsing water after washing hair leaves the hair soft; juice added to blue rinsing water when washing white silk will keep the silk white. For cleaning aluminium pans, if they become black, dip a soft cloth in the lemon juice and apply; afterwards rinse in warm water. For freshening stale vegetables soak for 1 hour in water to which the juice of a lemon has been added. Lemon juice in hot coffee will relieve headaches. It also has many table uses.

To candy peel of either lemon, orange or citron:—Place peel in salt and water for 4 days, changing water daily. Then boil peel until soft and drain. Make a thin syrup with 1lb. sugar and 1 quart water. Boil peel in this until clear. Make a thick syrup, add peel, and boil slowly until syrup candies. Dust peel with castor sugar, and leave in a warm oven over night.

THE VALUE OF WHEAT MEAL IN THE HOME.

[Miss IDA PEARCE, Beetaloo Valley.]

The wheat grain has three parts:—(1) Bran, or outer covering; (2) germ, or young plant; (3) kernel, or store of food for the germ. The bran and the germ are both removed in milling in order to obtain a white flour, which is made from the kernel. This entails considerable loss of protein, fat and mineral matter. Flour, as prepared by milling, consists of 57.8 per cent. starch, 9.5 per cent. protein, 1.3 per cent. water, 3 per cent. mineral salts, 5.2 per cent. fat, thus leaving 11.5 per cent. in the germ and bran. The bran is a useful laxative, so by using the whole meal one obtains the full value of the wheat. The wheat grown on farms could be used, and expense saved in buying other foods in its place.

It can be used in so many different ways that it becomes very desirable. Mixed with flour, it makes lovely bread; scones and biscuits. When boiled it makes delicious porridge, while baking it with treacle makes a refreshing drink.

To make wholemeal bread, use two-thirds plain flour and one-third wholemeal. For scones use 3 cups S.R. flour to 1 cup wholemeal; and for biscuits, 2 cups S.R. flour to 1 cup wholemeal.

To make coffee, sift enough meal to comfortably fill an ordinary-sized baking tin with the coarser grains, using the fine for porridge. Bake the coarse meal, stirring occasionally to prevent burning, and when light brown pour on 1 cup of treacle. Keep well stirred, as the treacle burns easily if the oven is too hot. When it is a fairly dark-brown it should be allowed to cool, when it can be crushed quite easily with a bottle or rolling pin. Kept in airtight tins, it loses neither value or flavour. To prepare the coffee, use 2 teaspoons to every cup of water. Boil for a few minutes, add some milk, sugar, and a little salt, and bring nearly to the boil again. After the coffee is drained the grains can be eaten with cream and sugar. They are a special favourite with children.

"A Week's Menu" was the subject of a paper contributed by Miss D. Noble, of the Nelshaby Branch, which enumerated a menu for each meal for each day of the week.

Miss D. Jose (Nelshaby) chose as the title of her paper "A Spring Menu." She prefaced her article with the following hints:—

1. See that the dishes chosen are perfectly balanced and seasonable.
2. Bear in mind any whims or fancies among the family. "Food faddists" abound to-day.
3. Arrange menu to suit stove, saucepans, and time-saving appliance available.
4. Study the marketing list intelligently, in order not to squander money.
5. Aim for a touch or originality, and vary dishes as much as possible.
6. The principal ingredient used for one dish should not appear in any other.
7. Two dishes of a similar nature should not appear on a menu.
8. Plan well ahead.

Miss Jose then gave a menu for week-day meals, followed by a number of recipes.

SUMMARY OF REPORTS RECEIVED.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, 1936.

River Murray, at Block E, Thursday, 18th June (Mr. J. O. K. Brigham, Box 65, Renmark, Secretary).

Upper North, at Eurelia, Wednesday, 15th July (Mr. E. S. Wall, Eurelia).

Murray Lands (west), at Karoonda (Yurgo Branch), Tuesday, 21st July (Mr. H. M. McKenzie, Yurgo).

Pinnaroo Line, at Pinnaroo, Thursday, July 23rd (Mr. H. L. Badman, Pinnaroo).

Eyre's Peninsula (east), at Kimba (Kelly Branch), Tuesday, 4th August (Mr. F. R. Illman, Box 64, Kimba).

Southern, at Inman Valley, Thursday, 20th August (Mr. S. F. Hacklin, Inman Valley).

Murray Lands (east), at Alawoona, Tuesday, 6th October (Mr. Angus Thomson, Alawoona).

Fruit (non-irrigated), at Greenock, Tuesday, 3rd November (Mr. A. Schubert, Greenock).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Pruning Competitions.

McLaren Flat, 30th May.

River Murray Branches—

Mypolonga (to be fixed).
Berri, 23rd June.
Barmera, 24th June.
Moorook, 25th June.
Cadell, 30th June.
Waikerie, 1st July.
Championship at Mypolonga, 3rd July.

Grain in Argentina on 1st March, 1936.

The report of the Department of Agriculture and Commerce of Argentina on the position of grain in that country is to hand, and from it the Director of Agriculture (Mr. W. J. Spafford) has made the following extracts:—

The area seeded to maize is estimated at 18,846,100 acres, and although the damage by locusts was great and was persisting at the time, it continued to look as though the yield per acre would equal that of last year. If this assumption is correct, the total yield will be about 455,500,000bush., for the average yield was about 24bush. 10lbs. per acre last year. After a normal deduction for seed and domestic consumption of 51,300,000bush., there will be quite 400,000,000bush., surplus for export. Besides this enormous quantity of maize available for export, there were still about 62,000,000bush., of last year's crop unsold on 1st March.

Although the normal wheat crop of Argentina is about 260,000,000bush., of which about 163,000,000bush., are exported, the drought experienced during the wheat-growing season was so severe that the 1935-36 crop was estimated to yield 145,000,000bush. only. There was a carry-over from the 1934-35 crop of about 19,000,000bush., so that after allowing for 96,000,000bush., for seed and domestic requirements, this year's surplus for export will be down to about 68,000,000bush. The exports of wheat and flour to the end of February reduced the surplus for export to about 68,000,000bush., on 1st March, 1936.

The linseed crop was also affected by drought, and instead of a normal crop of about 73,000,000bush., the 1935-36 yield is estimated to be about 54,000,000bush. Including the carry-over, making the allowance of 78,400,000bush., for seed and domestic requirements, and subtracting the exports to the end of February, there were still about 38,000,000bush., of linseed available for export at that date.

All of the winter and spring-growing crops of Argentina were affected by drought, and the quantities over and above local requirements are less than usual, with the exception of rye, but this appears to be due to the fact that there was a very large carry-over from the previous season.

The oat crops produced about 27,500,000bush., and of this quantity about 25,300,000bush., are required for seed and domestic purposes, but with the carry-over and because of the small amount sold to the end of February, there were just over 3,000,000bush., of oats as a surplus.

About 21,000,000bush., of barley were harvested, and because of a low local requrement of about 630,000bush., and a fairly heavy carry-over, there were about 19,000,000bush., still available for export at the end of February.

The yield of rye was low, only reaching about 5,700,000bush., but the carry-over was nearly equal to this amount, and seed and domestic requirements are only about 2,000,000bush., and so at the end of February there was the large surplus of about 9,000,000bush., not required in Argentina.

Canary seed, which has become important in Argentina, got a setback from the drought also, and the yield was brought down to about 960,000bush., about half of which is required locally, and after all allowances are made, the surplus for export at the end of February was about 650,000bush.

Millers' Prize for Wheat Crop Competitions.

Mr. R. F. Harry (Secretary of the Millers' Produce Company of South Australia, Limited) has intimated that his company has decided again to offer a millers' prize of £5 5s. to each of the districts conducting wheat crop competitions under the control of the Department of Agriculture. The prizes are offered on identically the same terms as those of last year, *i.e.*, that the only wheats ineligible for purposes of the Millers' prizes are Gallipoli, Free Gallipoli, Ghurka, Nabawa, and Waratah.

The inclusion of these prizes contributed to the revival of interest in crop competitions which was noticeable last year. District Secretaries have been informed of this offer, and individual members of Branches are asked to co-operate with Secretaries for the purpose of making further increases on the list of competitors. The highest number of entries was in 1928, when 634 crops were exhibited to the judges. In 1935 there were 407 entries; this number was, however, an increase of 79 over the 1934 entries.

AGRICULTURAL INQUIRIES.

[Replies supplied by W. J. SPAFFORD, Director of Agriculture.]

Availability of Superphosphate.

Clarendon Branch asks: "If an inch of rain falls shortly after superphosphate has been broadcast will the superphosphate be absorbed by the soil or will a quantity remain to be absorbed later?"

Reply—The principal constituent of superphosphate, from an agricultural point of view, is the calcium phosphate, and this is soluble in water, and provided it is kept in contact with water for some little time, all of it is dissolved. If the inch of rain is received from a steady downpour practically all of the water-soluble phosphate will be dissolved and sink into the soil, but if the rain shower is very heavy and of short duration the chances are that only portion of the calcium phosphate will be dissolved.

After the calcium phosphate has been absorbed by the soil, most of the gypsum in the superphosphate is left on the surface of the soil for a considerable time before it sinks in.

Top-Dressing.

"Is top-dressing as beneficial in a light rainfall as in a heavy rainfall district?"

Reply—In most countries soils of low rainfall districts are relatively more fertile than similar types of soils in heavy rainfall districts. This is also the case in South Australia, for most mineral plant foods except phosphorus, and practically all of our soils are equally deficient of the substance. Because of the extreme shortage of phosphorus in South Australia, applications of superphosphate have relatively similar beneficial effects on soils of similar type in low and high rainfall districts, up to the limits of growth controlled by climate and soil. Land in high rainfall districts capable of carrying 1 sheep per acre per year without manure might be made to carry 4 sheep per acre per year by annually top-dressing with 3cwts. superphosphate per acre, whilst land of the same type in a low rainfall district which would carry about half a sheep per acre per year might be brought up to a carrying capacity of 1½ sheep per acre per year by using 1cwt. superphosphate per acre each season. In both cases each 1cwt. of superphosphate would lead to an increased carrying capacity of 1 sheep per acre per year. It must be remembered, however, that there is a minimum average annual rainfall below which it is impossible to expect economic returns for the use of top-dressing of any kind.

HORTICULTURAL INQUIRIES.

[Replies supplied by A. G. STRICKLAND, M.Agr.Sc., Chief Horticultural Instructor.]

Maturity of Apples for Export.

Longwood Branch of the Agricultural Bureau: "How can a grower tell when an apple is 'too forward' for export?"

Reply—Apples must be landed on overseas markets before they reach full maturity, in order that the consumer on the other side of the world may get fruit which will develop full flavour, and be subject to no defects, such as internal breakdown. To make this possible, fruit must be picked at correct maturity, and if not to be placed on shipboard almost immediately, the fruit must then be held under cool conditions, which will retard further ripening—preferably in cool store. It should be realised that fruit held in warm sheds will ripen far more quickly than it would if left on the tree.

The best guide to maturity of apples is the ground colour of the skin; in a red apple like Jonathan, no attention should be paid to the red blush (except in regard to colour requirements), and the fruit should be picked when the green, unblushed portion of the skin is showing the faintest suspicion of yellow. If the ground colour is definitely yellow, at picking time, or at the time of packing, the fruit is then definitely "too forward" for export. As apples which are packed and held at warm temperatures ripen fairly quickly, fruit may easily appear in prime shipping condition at the time it leaves the grower's property, and yet be definitely too forward at the time of inspection and loading on ship.

Green apples such as Cleopatra and Granny Smith should be picked when the dark-green ground colour is taking on a lighter shade of green; here again, definite yellowing of the skin and softness of the pulp indicates over-maturity, and necessitates rejection of the fruit.

If care is taken to pick fruit at optimum maturity, as indicated above, and to hold it under the coolest possible conditions until it is placed in cool store or on board ship, growers should experience very few rejections on the grounds of over-maturity.

Apple Tree Stocks.

Clarendon Branch of the Agricultural Bureau asks: "Will a graft on the apple make any difference to the fruit produced if different stocks are used, and will the trees produce fruit true to type and flavour?"

Reply—It is well known that the particular root stock on which an apple variety is worked has definite influence on the growth and form of tree produced. The stock may affect type of growth, size of tree, and the time at which the tree comes into bearing. In England investigations on stock have been proceeding for many years at the East Malling Research Station, and a huge volume of information is available in regard to stock-scion relations. For instance, apple stocks have been standardised and classed as dwarfing, semi-dwarfing, vigorous, and very vigorous. In England, it is now possible when ordering apple trees, to specify a stock according to the type and size of tree desired.

Apart from the influence of rootstocks on growth, vigour, and cropping of trees, it has also been shown that roostocks may have a direct effect upon size, colour, and keeping quality of fruit produced. Furthermore, Dr. Wallace, of Long Ashton Research Station, has recorded the fact that under similar environmental conditions, rootstocks may occasion differences in the chemical composition of the fruit, and hence differences in quality and flavour.

Much work remains to be done upon the question of rootstock influence on type, quality, and flavour of fruit; however, there is ample evidence of the existence of such effects.

Agent-General's Report.

The Agent-General in London (Mr. C. F. G. McCann) reports on 17th April:—"Early arrivals of Australian apples are meeting with greater competition than is usual. There is quite a lot of Winesaps and Newtown Pippins from North America still in store, the former attractive only because of its wonderful colouring, and the last-named a real good utility apple. Argentine, too, is becoming a factor as an early apple supplier. Her ripening season is identical with ours, but her voyage of only 16 days gives her fruit the opportunity of arriving about three weeks before our first shipments, and this year's crop contains some magnificent Jonathans. South African apples are in greater evidence than usual, and are of good quality. A variety unknown to me, and which I have no recollection of having seen before, is attracting some attention, viz., Laxton Superb. This apple resembles a Jonathan in 3/4 colour, and the flavour is distinctly Cox Orange Pippin. Retailers tell me that they are getting repeat orders for this apple, as consumers like its flavour. Those I sampled were particularly good. The market is low. The abnormally cold weather, with ice, snow, sleet, rain, and, lastly, fog, is not at all conducive to an increase in apple consumption. It is hoped that, with the resumption of seasonable weather, a much better demand for apples will be stimulated. There is not much wrong with our fruit, and the Chief Horticultural Instructor and his officers are to be congratulated upon their care and attention in the supervision of the shipments.

"The *Glasgow Herald* of 9th April draws attention to a shipment by the s.s. *Nestor* of 12 Clydesdales, comprising 4 stallions and 8 mares, purchased by Mr. John B. Hamilton, of Maitland, South Australia. Reading the particulars of the consignment, it is evident that these horses have been selected from the best studs in Scotland, and should be a great acquisition to South Australia's horse breeding stock."

VETERINARY INQUIRIES.

[Replies supplied by the veterinary officers of the Stock and Brands Department.]

Worms in Foals.

"Saddleworth" reports foals that appear rough in coat and passing worms.

Reply—If the foals are running in a paddock with older horses or in a paddock where older horses have been, they would pick up the worms' eggs off the ground. Older animals may have quite a large number of worms without showing any symptoms. Worms are not infectious, but their eggs are passed out on to the ground and other horses grazing in the same paddock will become infected. To clear out the worms give ½ pint of raw linseed oil with 1oz. of turpentine in it, after starving for 12 hours; then give 1 tablespoon of Fowler's solution sprinkled on the food once daily for 14 days. Give chaff, crushed oats and bran. A little linseed meal would help considerably.

Pigs Stiff in Joints.

"Wasleys" reports young pigs very stiff in joints and almost unable to walk.

Reply—Supply the sow with plenty of greenfeed such as lucerne if possible. The trouble is probably due to a deficiency of vitamins which are found in greenstuffs. Give a mineral mixture of 10 parts of bone meal and charcoal and 1 part of salt.

Skin Disease in the Pig.

"Hon Secretary, Frayville Agricultural Bureau," reports mortality in a litter of young pigs, the skin of which goes black.

Reply—The information is not sufficient upon which to base a diagnosis, but suggests that the piglets may be affected with impetigo, a skin disease due to inoculation by bacteria. This disease may be associated with the presence of pig lice, but insanitary conditions may play a big part. Only young pigs (whose skin is soft and tender) contract the disease. Treatment indicated is to wash affected piglets in a solution of creolin (4 to 8 tablespoons to 5 pints of warm water) or dress with:—Kerosene, 4 tablespoons; raw linseed oil, 1 pint; shake well before use. Sump oil is sometimes used instead of raw linseed oil, but in hot weather it is apt to scald the pigs. Pigs should be kept in clean surroundings where they can obtain sufficient exercise in the fresh air. If lice are present, dress the pigs with the kerosene and oil dressing.

Stinkwort Poisoning of Sheep.

"Currency Creek" reports death of sheep running in a paddock in which Stinkwort is growing.

Reply—If a paddock of Stinkwort is to be grazed, the sheep should never be turned in on to it in hungry condition, or while it is wet with morning dew or showers of rain, more particularly when the Stinkwort is in the flowering stage of growth. Supplementary feeding should also be given either by hand-feeding or by alternative grazing on other grass pasture or stubble paddock.

PROFESSOR A. J. PERKINS RETIRES FROM THE DEPARTMENT OF AGRICULTURE.

FORTY-FOUR YEARS OF OUTSTANDINGLY USEFUL WORK.

PROFESSOR ARTHUR J PERKINS,
who retired from the Public Service of South Australia on 11th May, 1936.

"On the occasion of your retirement from the Public Service of South Australia, we desire to express to you our affectionate regards and esteem.

"You have rendered eminent service to the State during the past forty-four years, as Professor of Viticulture, Principal of the Roseworthy College, and finally as Director of Agriculture.

"Your zealous and untiring efforts for the improvement of agricultural practice in South Australia, and your substantial original contributions to agricultural science are widely appreciated. The rapid advancement of agriculture in the State during your period of office as Director of Agriculture is largely due to the influence of your wide knowledge, experience, and mature judgment in rural problems.

"We earnestly hope that you may long be spared to enjoy the leisure which you have so richly earned, and to witness the fruition of your work in the cause of agriculture."

[Such was the text of an illuminated address presented to Professor Perkins (Director of Agriculture), who retired from the Public Service on 11th May. The address, together with a typewriter, desk, and chair, was formally handed to him by the Minister of Agriculture (Hon. A. P. Blesing, M.L.C.), at a largely attended social given in his honour on 15th May by officers of the Department of Agriculture, representatives of the Waite Agricultural Research Institute, members of the Advisory Board of Agriculture and the Governing Council of Roseworthy Agricultural College, and other departments and organisations with which Professor Perkins was associated for many years.]

The retirement of Professor Perkins, on attaining the age-limit set for public servants, was a decided loss to the rural interests of the country, and a cause for the regret of his colleagues in the Department. For the past 44 years he has held prominent positions in the Public Service of the State, and few men have been so fortunate as to be able to inaugurate and carry to useful lengths so much work as he has achieved. The possession of an absolutely fearless nature, nothing diverted him from a course once set, and as a consequence most of his work has, and is, bearing fruit of value to the producers of the country. He remained at all times the friend and kindly adviser of all who approached him on any matter of a private or public nature.

Professor Perkins arrived in South Australia from Tunis in 1892, after having been educated in England and France, to take up the position of Professor of Viticulture and Oenology; and he retained this position until 1901, when he was appointed to the head of the Department under the title of Secretary of Agriculture. In 1904 he was made Principal of Roseworthy Agricultural College, and remained in charge of that institution for 10 years, although one of these was spent in a tour of Europe. During 1910 he investigated the agriculture of several European countries, and reported to the Government in a most entertaining book, the impressions gained during that tour. In 1914 he was appointed Director of Agriculture, which position he has filled with conspicuous ability from that date until the time of retirement.

An extremely versatile agriculturist, Professor Perkins has proved highly successful as an educationist, a very capable administrator, an agricultural economist of some note, and perhaps was even more outstanding as an agricultural experimentalist.

At the time of his arrival in the country in 1892, little was known of the correct method of pruning vines for the natural conditions which obtained, and many unsound wines were being placed on the market, but it was not long before he had taught vine-growers and wine-makers how to correct these serious deficiencies. His work with the production of spirits from raisins showed commercial interests the possibilities in that direction, and had something to do with the installation of distilleries on the River Murray Settlements. Altogether, he played a considerable part towards the prosperous position in which the important wine-making industry finds itself to-day.

As an agricultural experimentalist, Professor Perkins has been particularly prominent, and his wonderful foresight led him to undertake experimental work which was of the greatest importance at the time, and the extent of which was really amazing. He was the first in Australia to arrange permanent experimental plots on the lines followed for years at Rothamsted, the first to conduct actual digestibility tests, when he used horses on cereal hays, the first to undertake the improvement of cereals by systematic selection, and the first to work out the correct depth to sow agricultural seeds in our climate. He was early in the field with the cross-fertilisation of cereals, inaugurated the lamb-breeding experiments at Roseworthy, which eventually became so noted, and conducted experiments in manuring, liming, cultivation, rotation, feeding-off of crops, and in many other directions.

Professor Perkins has always been able to see the great possibilities for the production of pork for export, and has been a stalwart in support of the growing of olives. He also foresaw the trouble that was coming from the too rapid adoption of the tractor as the means of draught for farm implements, and consistently warned producers to go slowly, when practically all other advisers were luke-warm on the matter or actively advising its use. Of recent years, agricultural economics have occupied much of his time, and as a result he has contributed several very useful articles on the subject.

A prodigious writer throughout his official career, all experimental work undertaken by him has been fully and clearly reported upon, and besides these reports an enormous collection of articles dealing with all phases of South Australian agriculture has come from his pen.

A consistent supporter of the primary producer against all opposing interests, and a just head of the Department of Agriculture, Professor Perkins will be

APPOINTMENT OF MR. W. J. SPAFFORD AS DIRECTOR OF AGRICULTURE.

There has probably never been an appointment that was more confidently anticipated by primary producers than that of Mr. W. J. Spafford, R.D.A., as Director of Agriculture. Mr. Spafford has been well known throughout the State as Deputy Director of Agriculture and under his new official title he will be sincerely congratulated and welcomed by all. As a much travelled officer he has obtained, by observation and by personal acquaintanceship with farmers, a thoroughly intimate knowledge of the farming practices as applied to South Australian agriculture in the widest scope of its meaning—not confined to the growing of crops, but including the management of pastures, the raising of livestock, dairying, horticulture, viticulture and other phases of production suited to the State. Such attributes of versatility are essential for the successful control of a department of agriculture and for guiding the development of agricultural pursuits. Primary producers—no matter the sphere in which they may be engaged—should be assured, therefore, that under Mr. Spafford's directorship, there will be a continuance of that sound counsel which has characterized the work of the Department in the past.

MR. W. J. SPAFFORD, R.D.A.,
who was recently appointed Director of Agriculture

Mr. Spafford's first association with the Department of Agriculture was at Roseworthy Agricultural College in 1905 when, two years subsequent to gaining the diploma of that institution, he joined its staff as Assistant Experimentalist and later was appointed to the teaching staff. It was at Roseworthy that he bred varieties of wheats which are of prominence to-day and which have had some influence in increasing the wheat yields of the State. Ford, Sultan and Felix are three of his important wheats. Caliph, Daphne, and Queen Fan are among others bred by him and he had a hand in the selection of King's White from King's Early, Late Gluyas from Gluyas, as well as the purification of Gluyas from other types.

In July, 1914, with Professor Perkins who was then appointed Director of Agriculture, he was transferred to Adelaide and in 1927 he became Deputy Director. In that capacity he visited every part of the agricultural areas of South Australia and has kept in personal touch with producers in their own districts. Accordingly, he has acquired a fund of information on farming practices wherever crops of any kind are grown. As a lecturer, Mr. Spafford has gained a popularity well deserved because of a natural gift of imparting information in every day language on a wide range of subjects. He has been a most regular attendant at conferences where his addresses and his replies to questions have been attractive features of such gatherings. Many articles have been written by him for the pages of this Journal. With the full confidence of the farming community these works are eagerly sought and are regarded as text books on their particular subjects. Commissioned to inquire into the agriculture of countries in the same climatic zone as Australia, Mr. Spafford visited New Zealand, South America, and South Africa in 1934-35 and his report on this visit is well known to our readers. The large number of requests for addresses on this tour testify, not only to the value placed on the report, but to his popularity as a lecturer. Mr. Spafford has served on important Commissions and Committees, such as, among others, the Rural Settlement Commission, the Agricultural Settlement Committee, the Committee appointed to inquire into the effect of legislation for controlling butter and cheese, the Employment Promotion Council (he is the chairman of the Land Settlement Committee of that body) and for a while in 1932 he was Acting Principal of Roseworthy Agricultural College. As Director of Agriculture, he will take a seat on the Advisory Board of Agriculture and on the Governing Council of Roseworthy College.

FARM OUTBUILDINGS.

The above was the subject of a paper read by Mr. A. O. Steinborner at a meeting of the Brownlow Branch on April 8th. He stated that the proper arrangement of the outbuildings was just as important as any farm improvements. The stable should be to the south of the house, with the front facing north or north east, or away from the house. Much expenses in the erection of walls could be saved by building the cocky-chaff shed on one side of the stable, with the engine room and chaff shed on the other. The appearance also was improved by grouping the buildings. Feed was always handy, none being wasted as it often was when carried from one shed to another in windy weather. A stable with stone walls and a straw roof would be warmer in winter and cooler in summer. A wood and iron roof, however, was the most trouble-free and lasting. Separate stalls should be made for each two horses, with an extra stall to accommodate any increase in the team. The cow-shed, pig-sty and fowl house could be grouped together in order to save expense as well as time taken in walking when feeding, as all the stock were usually fed at the same time. The combined building should face east with the back towards the house, thus giving good shelter to the stock and a better appearance to the homestead. The wheat barn and store room containing feed for the fowls and pigs should be to the north side of the house and also under the one roof. The building should be of stone with an iron roof and cement floors. If possible the floors should be about two feet above ground level to facilitate loading and unloading. The implement shed, motor shed, blacksmith and work shop should be close together, and should be of wood and iron contruction to minimize the risk of fire. All outbuildings should be at least 1½ chains distant from the house to prevent dust and dirt reaching the house.

OUR WHEAT GROWING AREAS—PROFITABLE AND UNPROFITABLE.

[By Arthur J. Perkins, Director of Agriculture.]

1. INTRODUCTORY.

It was well known that the State of South Australia had been built upon foundations of Wool and Wheat: preponderatingly Wool in the earlier years of settlement, but eventually Wheat to a greater extent than Wool: so much so that it led subsequently to the complete absorption of the majority of settlers in Wheat growing, and to the neglect of other forms of rural activity. This peculiar phenomenon won for us the early derisive nickname ot the "farinaceous State," and what was worse, as we know to-day to our cost, it led to the settlement of Wheat Farmers in districts in which neither soil nor climatic conditions were suited to Wheat growing, with that cereal overwhelmingly the major farm crop.

In fairness to all concerned it should not, however, be overlooked that practically all land thrown open for closer settlement during the past 30 years has been almost exclusively Mallee land, and that apart from the surveying of farm blocks and roadways by Government officials, the heavy task of clearing mallee scrub of varying densities, and subsequently bringing the cleared land into profit—if such were possible—had been left to settlers whose meagre resources have rarely been equal to the task In such circumstances it can be asserted with confidence that without the assistance of Wheat from the earliest years of settlement, the early reclamation of vast areas of economically useless scrub land would to all intents and purposes have been impossible.

But because with the assistance of Wheat, 10 to 20 years of unremitting toil might eventually have led to the satisfactory reclamation of Mallee scrub, it does not follow that any of the crops grown during this preliminary period would have been profit bearing, *i.e.*, would have left a margin of profit to the grower after due satisfaction of the claims of interest on capital invested, of adequate provision for the replacement of rapidly wasting assets, of costs of necessary purchases of farming material, and labour, &c. And yet this work has usually been undertaken by men of very limited means. We cannot expect much from four or five wheat crops grown successively on the same area of land, nor even from later attempts of Wheat alternating with Bare Fallow on light Mallee lands. Subsequently, a crop of Oats was slipped in between the Wheat Crop and the year of Bare Fallow: and later again, as a concession to the clamour for better farming methods, one year's grazing of natural weed growth has at times succeeded the Oat Crop. The latter practice usually meant that the land would carry a wheat crop in every fourth year, a practice which, whilst satisfactory for good quality mallee land, was not suited to much of the light sandy land of low rainfall districts, from which successful crops cannot be expected more frequently than every seven to 10 years.

2. SUGGESTED REMEDIES.

But what is to be done with such land in intervening years of decennial Wheat crops? And how was the farmer to recoup himself for his considerably reduced wheat areas? As to the last point it can be stated that under the changes contemplated, mean wheat yields per acre would be considerably higher than those registered for these areas during the past 20 years: and as to the first point, in intervening years the land would be grazed by livestock, preferably sheep, besides carrying forage crops for supplementing the deficiencies of natural grazing.

From this it will be noted that I am not suggesting that these farms be converted into miniature station properties: very far from it. The management and handling of livestock on relatively small areas must differ radically from the methods of vast station properties, on which the requirements of livestock were met from the natural growth of grass and edible bush; and when the latter failed, the livestock died of starvation or was shifted to some other property. I am of the opinion that yearly grazing crops, such as Oats, will have to be sown: that forage crops will have to be cut and stacked, as hay or ensilage; and that grain such as Oats or Barley will have to be set aside in anticipation of periods of drought.

Success in animal husbandry of this kind will take years of apprenticeship, during the course of which the average farm will have to be changed to meet the requirements of livestock; smaller paddocks, better fences, adequate provision for water, natural or artificial shelter, &c.: all will have to be met. Hence, if the evil of unsatisfactory Wheat areas is to be given the solution I have suggested, it must be clear that the position could not be rushed, otherwise the cure would probably be worse than the evil. The conversion of these derelict wheat farms into Livestock Farms must therefore be a gradual process, and under adequate technical supervision. It remains to be said that not all of these farms would prove suitable for this purpose, chiefly because of inadequate areas. When such was the case, it would be necessary to group farms together, so as to provide an area sufficient to carry adequately not less than 600 ewes. From such a flock and reduced wheat area, the Labour Income of the Farmer and his family should be very much more satisfactory than from large areas under wheat yielding no more than 3bush. to 5bush. per acre.

3. RECOGNITION OF UNSUITABLE AREAS.

The fact that some of our wheat areas are far from profitable, and because of unfavourable climatic conditions stand little chance of ever becoming profitable, has generally been recognised: no attempt, however, has yet been made to separate apparently unprofitable areas from those that are supposedly profitable· and until this has been acceptably done, it does not seem probable that a definitely satisfactory solution to the problem of unprofitable wheat areas will be reached. It is of course true that, in the final issue decisions will concern individual farms rather than districts: in other words, that competent persons will be called upon to decide as to whether such and such a farm could be expected to grow wheat at a profit within the immediate future: and, if not, to what better purpose could the farm in question be put. On the other hand, since most of these Farms are situated in special districts, in which economic, climatic, and soil conditions are more or less similar, it would simplify the administrative side of the work if such districts were clearly defined: it is the object of this statement to show how, in my opinion, this could best be done.

In the matter of districts I have thought it wise to adopt the lowest territorial unit, of which we have consecutive statistical data, namely, the "*Hundred,*" the mean area of which is according to the Crown Lands Department 75,860 acres, or 118 square miles.

In this connection I have sought to compare the mean wheat performances of each wheat-growing Hundred over a period of 20 years: it seemed to me that if it could be shown that over a period of 20 consecutive years the mean Wheat yield of any hundred had been definitely unsatisfactory. then it was surely time to put the land to some better use. For the purpose I have taken the most modern 20 years' period available from the point of view of statistics, namely, the period closing on 30th June, 1935. Attention should be drawn to the fact that for some of the more recently-settled Hundreds we have not yet got statistical data covering a full period of 20 years: wherever such was the case for any Hundred, the actual number of years of which we have statistical data is shown in the Table at the end of this statement. Obviously, caution should be exercised in passing judgment on Hundreds on the basis of an insufficiently great number of years. It can be added that the particular 20-year period selected—1915-16 to 1934-35 inclusively—is on the whole favourable to unprofitable Hundreds, since it included the finest 12-year period of which we have record, namely, 1915-16 to 1926-27, during the course of which the mean yearly yield of the whole State was 12½bush. per acre and the mean yields of the several Statistical Divisions as follows:—

Mean Annual Yields per acre of Wheat in Statistical Divisions of the State in 12-year period, 1915-16 *to* 1926-27 *inclusively*:—

Divisions.	Mean Annual Yields Per Acre. Bush.
1. Central	14.30
2. Lower North	16.41
3. Upper North	12.83
4. South-East	12.99
5. Western	8.03
6. Murray Mallee	9.06

It will be admitted that the above record was entirely satisfactory: the record of the remaining eight years, on the other hand, was far less so: of these eight seasons, five were definitely unsatisfactory, and the balance no more than mediocre. The annual mean yield of the State which had been 12½bush. per acre in the 12-year period ending in 1926-27 fell to 8.94bush. per acre in the eight-year period ending in 1934-35.

The combination of these two periods, namely, the 20-year period ending in 1934-35, should therefore give us satisfactory standards of comparison, which would represent a reasonable compromise between favourable and unfavourable seasons. During this period the State mean annual yield per acre was 10.70bush., and the mean yields in the various Statistical Divisions as follows:—

Mean Annual Yield per acre of Wheat in Statistical Divisions of the State in 20-year period 1915-16 to 1934-35 *inclusively*:—

Divisions.	Mean Annual Yields Per Acre. Bush.
1. Central	13.88
2. Lower North	15.11
3. Upper North	10.00
4. South-East	14.48
5. Western	6.69
6. Murray Mallee	7.32

The next point is more difficult to settle namely, in the examination of the 20-year mean yields per acre of the various Hundreds: what limiting figure should be adopted in order to distinguish between profitableness and unprofitableness in Wheat growing? At the outset it must be recognised that such "limiting figure" must vary more or less from district to district: in other words on Eyre's Peninsula, for example, Wheat could be grown at a profit on a lower general mean yield per acre than in the South-East or in the Lower North, chiefly because in the latter districts higher land values reflected the fact that higher mean yields were possible than on the Peninsula, and the farmer who was unable to make good in these districts under average conditions must blame his own farming methods rather than the seasons or the land. Nevertheless, for the purposes of the present inquiry it does not seem necessary to stress the differences between district and district, in the matter of profitable or unprofitable wheat mean yields: in the main because the doubtful Wheat Hundreds are to be found chiefly in the two Mallee Statistical Divisions, namely, the Western and Murray Mallee Divisions, and to a less degree in the Upper North. It is fairly certain, too, that owing to similarity in environment, mean yields that would be considered unprofitable in one of these districts would be considered equally unprofitable in the others.

With a view to obviating possible future misconceptions, it is perhaps necessary to stress here that references in this statement to unprofitable or uneconomic mean yields of wheat did not in any way concern the mean yields registered for single seasons, but *exclusively mean yields calculated from the returns of 20 successive seasons.* It must be obvious that we cannot condemn a district because of apparently uneconomic yields in certain individual seasons: in such circumstances the profits of favourable seasons were supposed to make good the losses of unfavourable seasons: and apart from cases of land booms or of urgent personal requirements, it is on this basis that land values were more or less intuitively determined.

4. INFLUENCE OF WHEAT PRICES.

Obviously, too, in any settlement of this question the possible influence of mean prices offering for Wheat must also be given due consideration. For 74 years of which we have records the mean price realised for Wheat at outports has been 4s. 7½d. per bushel: or allowing 4d. for Rail freight, which is the mean rate in South Australia, 4s. 3½d. at railway sidings. On the other hand, for the 20-year period with which we are at present concerned, mean prices paid at outports for each season were as follows:—

	Per Bush.			Per Bush.			Per Bush.	
	s.	d.		s.	d.		s.	d.
1915-16	4	9	1922-23	4	11	1929-30	4	4
1916-17	4	9	1923-24	4	8	1930-31	2	3½
1917-18	4	9	1924-25	6	1	1931-32	3	2
1918-19	5	6	1925-26	6	2½	1932-33	2	9¾
1919-20	9	0	1926-27	5	3½	1933-34	2	7½
1920-21	8	0	1927-28	5	5¼	1934-35	3	0½
1921-22	5	0½	1928-29	4	8¾			

The average price of Wheat for these 20 years was 4s. 8d. per bushel at outports, or 4s. 4d. at railway sidings. In discussing the question of unprofitableness of certain Hundreds, we shall have to discard any idea of the recurrence of prices of 8s. to 9s. per bushel that characterised the early years that followed the Great War. I wish I could say the same of the low prices that have characterised the depression from which we are now emerging. The World has learnt that there was no difficulty in producing in one year considerably more wheat than could be consumed in that year, and until such knowledge becomes legendary by fluxion of time its influence should suffice to check the tendencies of momentary difficulties to encourage speculation and undue rise in price: and in the long run this would be of advantage not only to consumers, but to producers as well. It seems to me that for the next few decades we shall be safe in basing Wheat values on prices that should oscillate between 3s. and 5s. per bushel. At the maximum of 5s. I feel that we shall all agree that the crop returns of the average South Australian Farmer (excluding those situated in the unsound areas) and who according to the seasons should average from 12bush. to 20bush. per acre, should be amply remunerative. But what of those whose mean yields varied from 3bush. to 5bush. per acre? From such farms the gross returns per acre would be from 15s. to 25s.; and by no stretch of imagination can I conceive that such returns would suffice to meet inclusive costs of wheat growing, including interest on capital investments, provision for replacement of wasting assets, purchase of essential farming material, the payment of hired labour (if any), and the upkeep of the farmer and his family. And with wheat at 3s. per bushel the position would be proportionately worse. In the circumstances the continued solvency of those wheat growers who are situated in unsound areas cannot be anticipated; and any attempt temporarily to bolster up their financial position would be mistaken kindness unless they agreed to abandon wheat as the major enterprise of their farms.

5. SUGGESTIONS FOR LIMITS OF PROFITABLENESS IN WHEAT GROWING.

After careful consideration of the whole position, I have come to the conclusion that any farm, and any Hundred, in which the mean yield per acre over a period of 20 years or more could be shown to be less than 6bush., should be declared unsuitable for wheat growing and treated accordingly.

At the end of this statement I have prepared a Table in which all the Wheat growing Hundreds have been set out, grouped together in their respective Counties, and the respective Statistical Divisions to which they belong. The information given in Table V. comprises:—

Column 1.—Name of Hundreds, with the exception of County Adelaide in which the names of District Councils have been unavoidably substituted.

Column 2.—The number of seasons to which mean figures in succeeding columns correspond.

Column 3.—Mean yearly areas under Wheat over a period of 20 seasons closing with 1934-35 season inclusively, or such less number of seasons as Column 2 indicates.

Column 4.—Mean yearly total production of Wheat over a period of 20 seasons closing with 1934-35 inclusively, or such less number of seasons as column 2 indicates.

Column 5.—Mean yearly yield per acre of Wheat over a period of 20 seasons closing with 1934-35 season inclusively, or such less number of seasons as Column 2 indicates.

In Table V. all Hundreds in which the mean yields per acre are less than 6bush. names of Hundreds have been printed in heavier type, and all Hundreds in which the mean yields per acre attained 12bush. and over have been printed in lighter type. Data corresponding to those supplied for each Hundred have also been given for the Counties in which the Hundreds were situated.

6. MAP OF WHEAT GROWING HUNDREDS.

A special Map has been prepared by the Lands Department, to whom I desire to express my thanks, to illustrate graphically data set out in Table V.: but as this Map was unavoidably small in size, in order to avoid confusion, the information conveyed upon it has been confined to matters strictly relevant to the subject matter of this statement. The information given may be summarised as follows:—

1. The Map has been divided up into Hundreds (with the exception of County Adelaide which has been divided into District Councils shown in the enlargement). No attempt has been made to show Counties or Statistical Divisions.

2. In the space allotted to each Hundred (or District Council in County Adelaide) the name of the Hundred or District Council is given coupled with a number as follows:—Caldwell: 4.12, which means that during the 20-season period ending in 1934-35, or such less period as is shown in column 2 of Table V., the mean yearly yield per acre of the Hundred of Caldwell, situated in County Hopetoun

and the Western Statistical Division, was 4.12bush. only. Similarly, Bundaleer: 22.23, means that over the same period the mean yearly yield per acre of the Hundred of Bundaleer, situated in County Victoria and the Lower North Statistical Division was 22.23.

3. All Hundreds the mean yearly yields per acre of which during the 20-year period ending in 1934-35 were below 6bush. have been tinted in yellow: all those the mean yearly yields per acre of which over the same period were 12bush. and over have been tinted in blue: Hundreds with intermediate yields have been left in white.

4. "Goyder's Line" has been shown by a thick broken line coloured in bright red.

5. The isohyets, *i.e.*, lines connecting places with the same mean rainfall have been shown by thin continuous lines coloured in bright red. In the present instance these isohyets do not represent total rainfall, but rain falling during the growing period of the wheat crop, *i.e.*, April-November inclusively.

7. SUMMARISED EXAMINATION OF HUNDREDS YIELDING LESS THAN 6 BUSHELS PER ACRE.

A close examination of Table V. would show that out of the 470 Hundreds which have been producing Wheat in the 20-year period under consideration, there were 156 Hundreds in which the mean yearly yields per acre were less than 6bush. These doubtful Hundreds were distributed as follows in the six Statistical Divisions of the State:—

TABLE I.

Summarised data concerning Hundreds with Mean yields of less than 6bush. to the acre in 1915-16 to 1934-35 20-year periods—

Statistical Divisions.	Number of Hundreds.	Mean Yearly Area Under Wheat.	Mean Production.	
			Total.	Per Acre.
	Nos.	Acres.	Bush.	Bush.
Central	9	21,415	97,168	4.54
Lower North	4	3,667	17,716	4.83
Upper North	26	55,396	282,343	5.10
South-East	3	275	1,423	5.17
Western	87	407,925	2,026,439	4.97
Murray Mallee	27	198,804	1,045,462	5.26
The State..	156	687,482	3,470,551	5.05

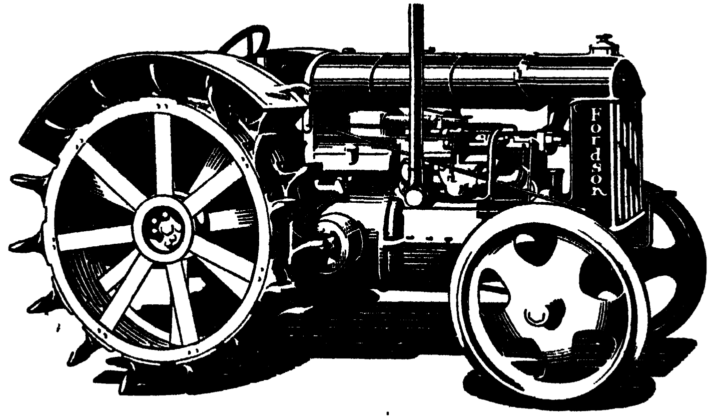
From the above it will be observed that during the 20-year period ending in 1934-35, the 156 doubtful Hundreds were responsible for a mean yearly total of 687,482 acres of wheat, or nearly one-quarter (23.5 per cent.) of the State mean total for the same period, namely, 2,925,248 acres: whereas for the same period the production of these hundreds was 3,470,551bush., or about one-eighth only of the State's mean production, namely, 31,309,130bush.

The depressing influence of the production of these doubtful Hundreds upon the State's mean yields per acre may be illustrated by the following example: for the 20-year period ending in 1934-35 the State mean yearly yield per acre was 10.70bush. only: if on the other hand we deducted area sown and wheat produced by the doubtful Hundreds from corresponding State figures the State mean yield per acre would rise from 10.70bush. to 12½bush.

8. HUNDREDS YIELDING LESS THAN 5 BUSHELS TO THE ACRE.

It is possible that it may be argued that 5bush. was a better limiting figure between profitable and unprofitable wheat crops than 6bush.: and although I do not admit the truth of any such contention, I submit below in Table II. data corresponding to those included in Table I.

SAVE TIME and MONEY IN PLOUGHING . . .
with a FORDSON



14 H.P. AT DRAWBAR — 26 H.P. ON BELT
(Tests by Mr. E. J. C. Rennie, Melb. University)

FORDSON IS POUNDS UNDER THE PRICE OF ANY OTHER TRACTOR OF EQUIVALENT POWER

COUNTER-BALANCED CRANKSHAFT . . . . HEAVY-DUTY TRANSMISSION . . . GOVERNOR CONTROL . . . SPECIAL AIR CLEANING SYSTEM . . . CRANKCASE VENTILATION . . . "HOT-SPOT" VAPORISER . . . CLUTCH PULLEY . . . POWER TAKE-OFF (optional at extra cost).

The English Fordson is the lowest-priced tractor per horse-power on the market. It saves time and money on every job—ploughing, harvesting, haulage or stationary work. Fordson is available with pneumatic tyres or approved wheel grips. Your local Ford dealer will explain the easy purchase terms provided by the special Fordson finance plan.

TABLE II.

Summarised data concerning Hundreds with Mean yields of less than 5bush. to the acre in the 1915-16 to 1934-35 20-year period:—

Statistical Divisions.	Number of Hundreds. Nos.	Mean Yearly Area Under Wheat. Acres.	Mean Production. Total. Bush.	Mean Production. Per Acre. Bush.
Central	8	21,195	95,881	4.52
Lower North	3	1,928	8,864	4.60
Upper North	11	13,604	56,438	4.15
South-East	1	17	66	3.88
Western	47	209,905	945,420	4.50
Murray Mallee	12	61,746	274,893	4.45
The State..	82	308,395	1,381,562	4.48

It will be observed that in the 20-year period ending in 1934-35 there were 82 Hundreds the mean yearly yields per acre of which were less than 5bush.; that the mean yearly area harvested for Wheat in these Hundreds was 308,395 acres, or 10.45 per cent. of the State mean area harvested for Wheat in that period; that the mean production of these Hundreds was 1,381,562bush., or 4.41 per cent. only of the mean total State production.

9. HUNDREDS WITH HIGH MEAN WHEAT PRODUCTION.

We shall now turn to the more gratifying consideration of the Hundreds with relatively high mean yields per acre: data concerning the latter have been summarised in Table III. below:—

TABLE III.

Summarising 1915-16 to 1934-1935 (20 seasons) data concerning Hundreds that averaged 12bush. and over:—

Statistical Divisions.	Number of Hundreds. Nos.	Mean Yearly Area Under Wheat. Acres.	Mean Annual Production. Total. Bush.	Mean Annual Production. Per Acre. Bush.
		12bush. but under 14bush.		
Central	24	99,242	1,288,398	12.98
Lower North	5	108,872	1,424,138	13.08
Upper North	1	14,074	169,099	12.02
South-East	7	1,845	23,817	12.96
Western	2	11,907	149,874	12.59
Murray Mallee	1	36,002	435,872	12.10
The State..	40	271,962	3,491,198	12.83
		14bush. but under 16bush.		
Central	16	119,809	1,854,952	15.48
Lower North	13	241,621	3,588,522	14.85
Upper North	3	45,968	680,734	14.81
South-East	6	8,793	136,841	15.56
Western	2	11,680	170,269	14.58
Murray Mallee	—	—	—	—
The State..	40	427,871	6,431,818	15.03
		16bush. and Over.		
Central	14	164,773	2,886,569	17.52
Lower North	22	284,536	5,131,996	18.04
Upper North	3	30,788	526,023	17.09
South-East	9	19,584	368,301	18.81
Western	—	—	—	—
Murray Mallee	—	—	—	—
The State..	48	499,681	8,912,889	17.84

From the above it will be observed that in the 20-year period ending in 1934-35:—

Forty Hundreds with an aggregate mean yearly area under Wheat of 271,962 **acres, or 9.30 per cent. of the State total mean area, and an aggregate** mean yearly **production of 3,491,198bush., or 11.15** per cent. of the State total mean production, **averaged** 12.83bush. per acre.

Forty Hundreds with an aggregate mean yearly area under Wheat of 427,871 acres, or 14.62 per cent. of the State total mean area, and an aggregate mean yearly production of 6,431,318bush., or 20.54 per cent. of the State total mean production, averaged 15.03bush. per acre.

Forty-eight Hundreds with an aggregate mean yearly area under Wheat of 499,681 acres, or 17.08 per cent. of the State total mean area, and an aggregate mean yearly production of 8,912,889bush., or 28.47 per cent. of the State total mean production, averaged 17.84bush. per acre.

In contrast with the disappointing yields with which we have hitherto dealt, those set out in Table III. are much to the credit of the farmers responsible for them.

Finally, I have indicated in Table IV. in order of merit all Hundreds which averaged 18bush. or over in the 1915-16 to 1934-35 period.

TABLE IV.—*Showing data concerning all Hundreds that yielded* 18*bush. or over per acre in the* 1915-16 *to* 1934-35 *period.*

Order.	Name of Hundred.	Name of County.	Mean Area per Annum.	Mean Production per Annum.	
				Total.	Per Acre.
			Acres.	Bushels.	Bushels.
1	Gambier	Grey	147	3,709	25·19
2	Mount Muirhead	Grey	1,992	44,650	22·41
3	Bundaleer	Victoria	13,858	308,128	22·23
4	Darling	Frome	582	12,697	21·83
5	Hindmarsh	Grey	775	15,880	20·49
6	Blanche	Grey	215	4,237	19·74
7	Maitland	Fergusson	21,502	421,109	19·58
8	Milne	Stanley	12,111	232,826	19·22
9	Anne	Victoria	5,417	103,694	19·14
10	Stanley	Stanley	18,497	352,967	19·08
11	Saddleworth	Light	9,808	186,640	19·03
12	Andrews	Stanley	13,001	246,486	18·96
	Hart	Stanley	14,901	282,550	18·96
14	Wongyarra	Frome	7,781	147,232	18·92
15	Narridy	Victoria	11,251	212,304	18·87
16	Tatiara	Buckingham	12,779	240,046	18·79
17	Curramulka	Fergusson	12,119	237,449	18·76
18	Yackamoorundie	Stanley	9,481	176,540	18·62
19	Hanson	Stanley	13,958	258,985	18·55
20	Alma	Gawler	17,392	317,831	18·27
21	Reynolds	Victoria	12,409	224,733	18·11
22	Yangya	Victoria	13,183	238,254	18·07
	22 Hundreds		223,159	4,268,947	19·13

The area covered by the Wheat crops of these 22 Hundreds corresponded to 7.63 per cent. of the total State area only; whereas the production of the same Hundreds corresponded to 13.63 per cent. of the Total State Production.

10. "GOYDER'S LINE."

"Goyder's Line" has been shown as a thick broken bright red line on the Map that accompanies this statement. This line was laid down in 1865, that is to say, 29 years after the foundation of the Colony, by G. W. Goyder, who at the time and many years subsequently held the position of Surveyor-General. His object had been to set down a line of demarcation between pastoral areas that had suffered intensely from the effects of two consecutive years of drought and those that had not so suffered. The special requirements of cultivated crops were certainly not in his mind, as at that time cultivation does not appear to have extended much north of Clare. Later on, however, a tendency arose to make use of this line for the purpose of distinguishing between land that was suitable for farming purposes and land that was not suitable. Needless to add that only land to the South of the line was considered suitable for farming. Later on, however, the gradual absorption into cultivation of land available South of the line, led to farming excursions outside the line, and particularly so in recent times. Hence, it will be of interest to ascertain how those Hundreds that are situated outside Goyder's line have fared during the 20-year period which ended in 1934-35. But before examining available facts in the matter, I propose giving a brief description of the line for the benefit of those who are not familiar with it.

Goyder's Line makes an easterly start from the Victorian border about 4 miles south of Peebinga: it proceeds in a north-westerly direction, cutting off a narrow triangle of the southern portion of County Albert, about four-fifths of the area of which lie outside the line. The latter enters County Eyre at Swan Reach, and proceeds steeply in a north-north-westerly direction, leaving one-half of County Eyre outside the line. It subsequently enters County Burra a mile or so from Robertstown, taking an almost northerly direction, and leaving three-quarters of the County outside the line. It then cuts across the South-west corner of County Kimberley, and proceeds in a north-westerly direction by way of Yatina to the centre of County Dalhousie. From this point it dips steeply in a south-south-westerly direction into County Frome to the level of Murraytown, but about 19 miles east of the town: the line then rises again on an equally steep grade but in a north-westerly direction, skirting the Northern foothills of Mount Remarkable, and falling steeply in a regular south-easterly curve to the level of Crystal Brook, and thence in a south-westerly direction, until it reaches the sea at Port Hughes.

Across the Gulf, on Eyre's Peninsula, Goyder's Line starts from the seacoast at a point four miles west of Point Gibbon: thence it proceeds north-westerly, without appreciable change of direction, coming to an end in the Hundred of Hague, about eight miles North-west of Nunjikompita. In this regular North-westerly progress the line passes successively through the following Hundreds:—Boothby, Mann, Yadnarie, Smeaton, Darke, Cootra, Mamblin, Wannamanna, Wudinna, Pygery, Pinbong, Minnipa, Pildappa, Condada, Kaldoonera, Yantanabie, Wallala, Petina, Nannyah, and Hague. All land west of this point has been deemed to be outside the line.

Let us now consider the extent to which Wheat growing outside Goyder's Line can be considered to have succeeded.

MURRAY MALLEE DIVISION.

Starting from the Victorian border, Goyder's Line divides the Murray Mallee Statistical Division into two approximately equal parts: to the north Counties Young, Hamley, Alfred, approximately seven-eighths of County Albert and one-sixteenth of County Chandos are outside the line. The balance of the area falls within the line.

In Counties Hamley and Young, north of the River Murray, the highest mean yield per acre secured during the 20-year period under consideration by any Hundred was 5.55bush. per acre (Hundred of Parcoola): and we can safely claim that neither county is suited to the growing of Wheat as a major farm crop.

In County Alfred, which lies south of the River, but is also wholly outside Goyder's line, one Hundred only, namely, Hundred of Allen, did not reach 6bush. per acre in the 20-year period ending in 1934-35. It is apparent therefore that there is no reason for discountenancing Wheat farming in County Alfred.

In County Alfred, which lies south of the River, but is also wholly outside partly without Goyder's Line, there were eight Hundreds out of 13 which averaged less than 6bush. per acre in the 20-year period under consideration, namely: Bakara (5.83bush.), Cadell (5.04bush.), Holder (4.76bush.), Mantung (5.40bush.), Moorook (5.45bush.), Paisley (5.75bush.), and Waikerie (4.54bush.), all of which lie outside the line and do not appear to have justified themselves as Wheat growing hundreds. Of the Hundreds lying outside the line Murbko alone had a mean yield of 6bush. or over, namely, 6.52bush. per acre.

On the other hand in County Chandos, the four Northern Hundreds which are partly outside the line averaged less than 6bush. per acre in the 20-year period, namely, Auld (3.39bush.), Billiatt (3.41bush.), Kingsford (4.49bush.), and Peebinga (4.50bush.). They cannot therefore be said to have justified themselves as Wheat-growing Hundreds, as yet: I say as yet, as none of them has completed a full 20-year test: the records varying from nine years in Billiatt to 16 years in Peebinga.

Although County Buccleuch was wholly within Goyder's Line it included six Hundreds out of 16 the mean yields of which did not reach 6bush. in the 20-year period, namely, Kirkpatrick (5.16bush.), Livingstone (5.34bush.), Molineux (5.95bush.), McPherson (5.99bush.), Sherlock (5.71bush.), and Strawbridge (5.56bush.). It is probable that the failure of these Hundreds is attributable more to soil than to climatic condition: and the position may possibly be improved in the course of time: it is generally possible to improve faulty soil conditions, but rarely those that relate to climate.

In County Russell, which was wholly within the line, the Hundred of Ettrick alone fell below the standard, namely, 5.31bush.: this was due mainly to unfavourable soil conditions.

CENTRAL DIVISION.

Goyder's line enters the Central Division at Swan Reach, and proceeds diagonally across County Eyre to Robertstown. This County includes eight Hundreds out of 13 that do not come up to the requisite standard, namely, Anna (4.90bush.), Beatty (4.55bush.), Bower (4.36bush), Brownlow (4.48bush), Eba (3.63bush.), Fisher (5.86bush.), Hay (3.41bush.), and Skurray (3.28bush.), all of which are wholly or partly outside the line. None can be said to have justified attempts to farm with Wheat as the major crop.

LOWER NORTH DIVISION.

From County Eyre the line enters the Lower North along the Western quarter of County Burra: this County includes three Hundreds that failed to reach the requisite standard, all of which were situated outside the line, namely, Bundey (4.69bush.), Lindley (4.17bush.), and Maude (4.07bush.). In none of these three Hundreds is continued Wheat-growing justified.

From County Burra Goyder's line cuts across the South-western corner of County Kimberley on its way to the Upper North Division. County Kimberley contains one out of four Hundreds that was below minimum requirements, namely, Parnaroo (5.09bush.). The remaining Hundreds although all outside the line have mean yields varying from 6.03bush. to 10.10bush.

Apart from the above the coastal areas of Counties Victoria and Daly are also to a shallow extent outside Goyder's line: but in every instance individual mean yields of the Hundreds of these two fine Counties are considerably above the mean requirements of successful Wheat-growing: the lowest mean yield in County Daly was 11.20bush. (Mundoora) and in County Victoria 8.32bush. (Pirie).

UPPER NORTH STATISTICAL DIVISION.

In the Upper North Division there are 10 Counties, eight of which are wholly outside Goyder's line and the remaining two of which—Counties Frome and Dalhousie—have three-quarters of their areas outside the line. In seven out of these 10 Counties Wheat is being grown more or less extensively.

In County Frome, Hundreds of Coonato (3.79bush.), Davenport (3.55bush.), and Winninowie (3.94bush.) should be definitely discarded as Wheat growing areas: and the same can be said of Hundreds of Erskine (5.24bush.), Oladdie (5.21bush.), Walloway (5.09bush.), and Yalpara (1.45bush.) in County Dalhousie.

In County Herbert, apart from Coglin (6.68bush.), the remaining five Hundreds should be discarded as Wheat growing propositions. In County Newcastle the same can be said of Hundreds of Coolcunda (5.32bush.), Kanyacka (4.92bush.), Moockra (5.66bush.), and Palmer (5.48bush.). And the same, again, of all the Hundreds of County Granville with the exception of Hundreds of Wirreanda (6.83bush.), and Yednalue (6.98bush.): and of all the Hundreds of Counties of Blachford and Hanson, with the exception of Wonoka (6.19bush.) in Blachford, and Moralana (7.30bush.) in Hanson.

SOUTH-EAST STATISTICAL DIVISION.

The whole of this Division is well within Goyder's line, and the low yields in some of the Hundreds of this Division are attributable in the main to soil poverty or defective drainage, both of which as a rule can in time be remedied. Attention is drawn to apparently unsuitable Hundreds, namely, County Buckingham: Archibald (5.25bush.), and County Robe: Ross (5.27bush.), Waterhouse (3.82bush.).

WESTERN STATISTICAL DIVISION.

It is in this Division that doubtful Hundreds are most frequent: out of 140 Hundreds in which Wheat was grown more or less extensively, 74, or more than one-half, have mean yields per acre very appreciably below minimum in requirements: it must not be forgotten, however, that in many Hundreds the process of reclamation has not yet gone sufficiently far to permit of definite judgment in the matter.

Out of the 13 Counties in this Division three are wholly within Goyder's Line, namely, Counties Flinders, Musgrave, and Robinson: Counties Jervois and Le Hunte are one-half within and one-half without the line, and County Dufferin one-third within and the balance without. The remaining seven Counties are outside the line.

In the three Western Counties—Hopetoun, Kintore, and Way—there are 20-year records for each Hundred, with the exception of Sturdee (18 years): in the circumstances and in view of the fact that mean yields of all Hundreds in these Counties were below minimum requirements with the exception of those of Miller (6.33bush.) in County Hopetoun, and of Catt (6.07bush.), and Guthrie (6.19bush.) in County Way, I am of the opinion that the practice of farming these hundreds on the basis of Wheat as a major crop should be abandoned.

The same can be said of all the Hundreds in County Dufferin with the exception of Petina (7.03bush.). It should be added, however, that Koolgera (16 years), Nannyah (11 years), and Pureba (11 years) have not completed the full cycle of 20 years, and that due weight should certainly be given to this fact.

In County Robinson, which with the exception of its extreme north-eastern corner is within Goyder's line, there were nine out of 22 Hundreds that were below minimum requirements. Of these five have completed the 20-year cycle, namely, Cungena (5.53bush.), Finlayson (5.54bush.), Ripon (5.15bush.), Tarlton (5.72bush.), and Travers (5.19bush.), and should probably be withdrawn from the list of Wheat-growing Hundreds. The balance have been farmed for shorter periods, namely, Moorkatabie (eight years), Carina (16 years), Chandada (16 years), and Karcultaby (18 years), and should probably be kept under observation.

One Hundred only has been proclaimed in County Bosanquet, namely, Pildappa, which over a period of eight years has yielded 5.53bush. per acre: its future progress should be watched.

Approximately one-half of County Le Hunte is situated outside Goyder's Line. Nine out of 14 Hundreds in this County had mean yields below minimum requirements: of these one only completed the 20-year cycle, namely, Wannamana (5.53bush.); Balabie (5.33bush.) has records of 19 seasons: Kappacoola (5.13bush.) and Warramboo (5.21bush.) of 18: Mamblin (3.96bush.) of 17: Pinbong (4.45bush.) of 10: Pordia (5.02bush.) of seven: Cootra (4.62bush.) and Koongawa (5.57bush.) of six. Hence I am inclined to suspend judgment as to the future possibilities of this County.

County Buxton, which is wholly outside Goyder's Line, has three Hundreds only in which mean yields have been satisfactory, namely, Cortlinye (6.22bush.), Kelly (8.06bush.), and Solomon (6.76bush.). The nine remaining Hundreds have mean yields much below minimum requirements. It remains to be stated that in no one case has any of these doubtful Hundreds completed the 20-year cycle: and the only one that has approached it is the Hundred of Moseley (4.06bush.) with 19 years to its credit, and which can probably be definitely recognised as unsuitable for Wheat growing. The records of the other Hundreds vary from seven to 11 seasons, and whilst it is highly probable that most of them will eventually be found to be unsuitable for Wheat growing as a major farming operation, I hesitate to express a definite opinion on a period which had been characterised by an exceptionally large majority of unsatisfactory seasons.

Approximately one-half of County Jervois lies outside Goyder's Line, and 14 out of 31 Hundreds in this County have unsatisfactory mean Wheat yields. It should be pointed out, however, that seven Hundreds that have yields above 6bush. are situated outside Goyder's Line: namely, Campoona (7.58bush), Hawker (8.19bush.), Jamieson (10.11bush.), Mangalo (8.21bush.), Mann (9.26bush.), Miltalie (7.55bush.), and Pascoe (7.88bush.). Of the doubtful Hundreds 10 have a record of 20 seasons, and should therefore be discarded, while four have records varying from three to 14 seasons, and should be carefully watched.

Counties York and Manchester are both definitely outside Goyder's Line: although with the exception of Hundreds of Ash (20 years) and Randell (18 years) none of these Hundreds has been carrying wheat for any considerable time, one can, I think, consider them to be unsuited to Wheat growing from the viewpoint of the persent statement.

In County Musgrave there are four Hundreds out of 14 that are below minimum requirements, and in Flinders three out of 15; both Counties are well within Goyder's Line, and in both rainfall conditions are usually satisfactory. In the circumstances I see no reason why special steps should be taken to discourage Wheat-growing in the apparently doubtful Hundreds.

11. APRIL-NOVEMBER ISOHYETS.

These Isohyets which are coloured bright red indicate the limits of mean April-November rain throughout the State: the lines have been shown at intervals of 3in. of mean rain.

It will be noted, in the first place that there are very few Hundreds with a mean Wheat yield of 6bush. or over outside the 9in. April-November Isohyet. The exceptions are Murtho (6.36bush.), Paringa (6.19bush.), Gordon (8.57bush.), Bookpurnong (7.56bush.), and Pyap (7.33bush) in County Alfred: Coglin (6.68bush.) in County Herbert: Wirreanda (6.83bush.) and Yednalue (6.98bush.)

in County Granville: and Petina (7.01bush.) in County Dufferin. On the other hand there are many Hundreds within the April-November 9in. isohyet, the mean yields of which were below 6bush. *We are entitled to assume therefore that any district with a mean April-November rainfall below 9in. was open to suspicion from the standpoint of Wheat-growing.*

On the other hand the most consistent satisfactory Wheat returns seem to have been registered for those Hundreds in which the mean April-November rainfall varied from 15in. to 18in.

12. CONCLUDING REMARKS.

The fact that this Report has been prepared and written in the busy closing days of my occupancy of the office of Director of Agriculture must be my excuse for its roughness and unavoidable imperfections. I have endeavoured to set up a standard which should enable us to distinguish between profitable and unprofitable Wheat-growing Hundreds, whenever Wheat was made the dominant factor on the farm. In this connection, I have suggested a mean yield of not less than 6bush. to the acre over a period of 20 successive seasons. And for the purpose I have adopted in this Report the most recent 20-year period of which we had adequate statistical data, namely, the 20-year period closing in 1934-35 inclusively. These mean yields of all the Wheat-growing Hundreds of the State coupled with other relevant data have been shown in detail in Table V. at the end of this Report: the mean yields have also been shown on a Map of the Hundreds which accompanies this Report.

If such a standard were adopted or any other one, the next step would concern its application in practice. It should be made clear that in the great majority of cases the landholder himself was not to blame for the low yields of his Wheat fields. For the most part these unsatisfactory holdings were situated in areas comparatively recently thrown open to occupation, and the landowners have given years of toil and all the capital they could command to the reclamation of areas which have eventually been found to be unsuitable for wheat-growing. In the circumstances there would seem to be some moral obligation upon the community to re-establish these men who have spent so many years of their life in the national task of endeavouring to reclaim the wilderness. But assistance towards such an end which took the form of monetary bonuses to be spent in continued attempts to grow wheat at a loss was surely the worst possible form of assistance that could possibly be given, from the standpoint of both the State and the settler: in reality it was no assistance at all. If assistance were to be given—and in my opinion it must be given—it should be towards assisting occupants of unprofitable wheat farms to convert their holdings into livestock propositions upon which Wheat would occupy only a very secondary position. I have not in view so many miniature station properties, which could not possibly succeed, but farms upon which sheep husbandry would be practised on relatively small areas: and with the latter should be associated a few cows wherever a reasonable outlet for cream existed. Crops would still have to be raised, but not for sale, but for consumption by livestock. I have suggested a flock of 600 Ewes: and I realise that some of the properties in question were not sufficiently large for the purpose. This would imply the necessity of merging two or more farms into one, and the transference of some families to other districts. Some such scheme should be put in hand, but to no greater extent than was absolutely necessary.

I have had many statements and reports to prepare during my 44 years of service: and it is some satisfaction to reflect that for the most part they have been written for the benefit of others. It is too much to expect that all should have succeeded: but I trust that some at least will have been helpful to the community. Whether such will be the fate of this my last official Report, I do not know; but I hope that it may be.

TABLE V.—*Showing Mean* 1915-1935 (20 *seasons*) *Statistical data concerning Wheat grown in the several Hundreds of the State.*

Names of hundreds in which mean yields per acre are less than 6bush. are printed in heavier type, and hundreds in which mean yields are 12bush. and over are printed in italics.

Note.—In County Adelaide, District Council areas have been unavoidably substituted for Hundreds.

SOUTH AUSTRALIAN F.A.Q. WHEATS.

The Acting Director of Chemistry (Mr. C. E. Chapman) has submitted to the Minister of Agriculture (Hon. A. P. Blesing, M.L.C.) the following report on the results of the milling, chemical and baking tests on the 1935-36 season's F.A.Q. wheat.

WHEAT.

	1934-33.	1934-35.	1935-36.
Moisture	9·9%	10·1%	10·8%
Impurities (Screenings, &c.)	—	4·2%	4·0%
Protein (N x 5·7)	11·1%	10·7%	11·1%
Bushel Weight	60lbs.	60½lbs.	63½lbs.
Flour Yield	71·1%	70·8%	72·1%

The Protein was calculated on wheat containing 10 per cent. moisure.

FLOUR.

	1933-34.	1934-35.	1935-36.
Ash	0·44%	0·44%	0·45%
Protein (N x 5·7)	9·2%	8·3%	9·1%
Wet Gluten	24·2%	23·8%	27·3%
Dry Gluten	8·6%	8·1%	9·0%
Water Absorption	56·0%	56·0%	56·0%
Hydrated Maltose	1·36%	1·70%	1·55%
Colour	Excellent	Excellent	Very Good
Standard Loaf Volume	437mls.	425mls.	442mls.
Standard Loaf Weight	133·4 grams	131·4 grams	131·1 grams

The analyses of the flour were calculated on flour containing 13·5 per cent. moisture.

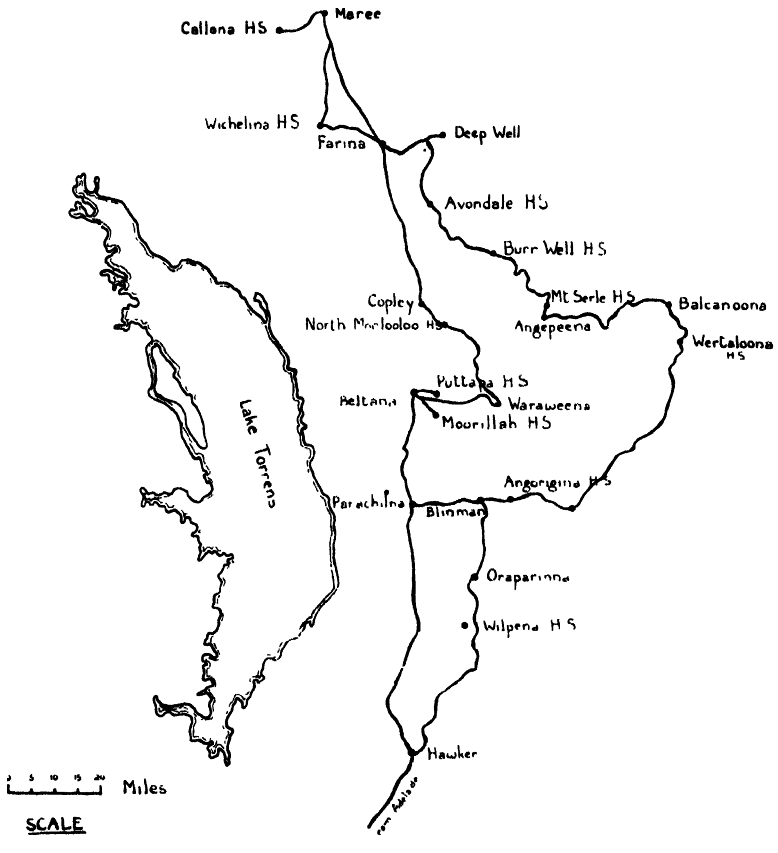
The figures obtained show that this season's wheat is of superior quality to that grown last season, and is equal to that of the year 1933-34.

Unfortunately there are no complete records of tests made on South Australian F.A.Q. Wheat previous to that of 1933-34, and therefore it is not possible to determine whether there has been a decline during recent years in the quality of South Australian Wheat. It is, however, gratifying to note that there is a decided improvement in this season's sample when compared with that grown the previous season.

A PRELIMINARY SURVEY OF THE FAR NORTH DISTRICT AS A POSSIBLE ENDEMIC AREA FOR PLAGUE GRASSHOPPERS.

[By H. G. Andrewartha, Waite Agricultural Research Institute, University of Adelaide.]

A previous paper discussed preliminary surveys of the north-eastern pastoral district and the north-western (Gawler Ranges) district.* During the present trip a survey was made of the area made up of the Flinders Ranges and the plains immediately to the west and east of them. The accompanying sketch map shows the route which was followed. As in previous surveys, information obtained from making collections at intervals along the route, was supplemented by conversation with pastoralists living in the district.



SKETCH MAP.

Showing route followed in survey of the Far North pastoral district, April, 1936.

The whole of the area which was traversed is at present suffering from drought; it had a desolate, drought-stricken appearance, the plains to the west of the ranges appearing even more barren than the ranges. Yet *Chortoicetes terminifera* was present over the whole area. It was strikingly the dominant species. Certain other *Acridids* were present in limited numbers in specialised habitats (*e.g.,* in ti-tree or gum creeks), but *Chortoicetes* appeared to be the only occupant of the more generalised type of habitat such as the open plain, the stony hillside, the flat water-course or depression, or the crab-hole. It was found in all these places. No attempt was made to form a quantitative estimate of the density of the grasshoppers. They occurred only sparsely in the more barren places, such as stony plains or hillsides, where there seemed to be little or no food for them. In such situations one or two adults might be disturbed in a mile. They tended to be more numerous in local areas (such as crab-holes, creek beds, and depressions) where there was a little green herbage; but nowhere were they observed to be at all dense or to show any tendency towards gregariousness. In certain of these areas the density was such that an adult might be disturbed every two or three yards.

There was no uniformity in the plants growing on those small areas in which *Chortoicetes* appeared to be concentrated. In some, saltbush (*Atriplex*) was dominant, in others various grasses and in others there was a wide variety of herbaceous plants. The general impression was that the nature of the plant was unimportant; so long as it could provide green food it was attractive to the grasshopper.

Another striking feature of the *Chortoicetes* population was the unusually high proportion of large green forms. No quantitative figures are available but the general impression gathered was that more than 50 per cent. of the individuals seen were green or tending to be greenish.

It was not possible to trace back the history of the last outbreak in this district with sufficient accuracy. There can be little doubt that there were swarms of *Chortoicetes* flying in the Flinders Range in the spring of 1934. Some, at least, of these were bred locally, from eggs which were laid probably in the autumn of that year. There is some evidence that grasshoppers were dense (but not gregarious) in the spring of 1931. There is no record from the Flinders Ranges of swarms during 1932 or 1933. At Callana (west of Maree) a swarm was observed flying in a southerly direction, probably about May of 1933. It seems probable that the Flinders Ranges district was not an important intermediate breeding ground during the outbreak which reached its climax in the wheat belt in the spring of 1934.

* 1936, Andrewartha, H. G.: *Journ. Agric. Sth. Australia,* Vol. 39, p. 1031.

FOOTROT IN SHEEP.

At the April meeting of the Koppio Branch Mr. F. Whittaker spoke on footrot in sheep. He had had experience of footrot, and considered it to be the worst disease that sheep could become affected with. It was difficult and expensive to cure, involving constant attention to the infected animals and isolation from the remainder of the flock. He recommended a footbath solution of 1lb. of bluestone to 2galls. of water, the sheep being treated in a trough once a fortnight until cured. The hoof should be cut away and cleaned, with all abscesses drained and dressed with a disinfectant solution of Stockholm tar and lysol. Footrot might occur in the district when top-dressing became universal practice and more feed was grown on low-lying, muddy country. He had seen footrot in a district of 17in. rainfall.

RED LETTER DAYS

IN

South Australia's Centenary Calendar

SEPT. 5 to SEPT. 12.

Royal Spring Show

7 Days and 7 Nights.

ENTRIES CLOSE–

PIG PRODUCTS IMPORTED BY THE UNITED KINGDOM IN 1935, EXTRACTS FROM REPORTS OF THE IMPERIAL ECONOMIC COMMITTEE.

A.—Bacon.

In 1935, Denmark was much the most important source of imported bacon, but shipments were reduced by 11 per cent. on the 1934 figures. Canada, the second largest source continued to advance, and imports from this country were 3 per cent. higher than in the previous year, while there was a further increase of 25 per cent. in imports from the Irish Free State. Imports from most other principal foreign sources of supply declined. The arrangement allowing foreign countries not specifically restricted to ship not more than 400cwts. bacon per week encouraged several countries which previously scarcely figured as sources of supply, and of these some Southern European countries and France showed the greatest relative increase.

C.—FRESH PORK.

All imports of fresh pork into the United Kingdom are from the Irish Free State, and although the decline in imports from this source were very considerable from 1932, when 262,151cwts. were imported, they were in 1935, about the same as in 1934. The imports in 1933 were 194,695cwts., in 1934 they were still further reduced to 143,771cwts., and in 1935 amounted to 142,841cwts.

D.—CHILLED AND FROZEN PORK.

New Zealand and Australia are particularly interested in the import trade of the United Kingdom in Chilled and Frozen Pork, and the most marked feature of the trade in recent years has been the rapid development of supplies from these countries. Empire supplies increased by 23 per cent. in 1935, and accounted for 70 per cent. of all imports.

FOR THE *FAST* MOTORIST

Ethyl has it!

POWER! Power for SPEED—all the speed your engine was built to give—you'll get with Super Plume Ethyl. Knockless power for taking steep hills FAST, in top, without harm to your engine. Economical Power for higher speeds with lower fuel consumption. Try 5 gallons! You'll be surprised at its Split-second Starting, too.

PAPERS READ AT CONFERENCES.

LOWER SOUTH-EAST, KYBYBOLITE, 8TH APRIL, 1936.

OUR KYBYBOLITE EXPERIMENTAL FARM.

[E. C. H. Schinckel (Kybybolite).]

Comprising an area of 1,000 acres surrounding the homestead of the old Kybybolite Estate, it was established as an experimental farm in 1906, just 30 years ago. Its original experiments were conducted in the growing of cereal crops, but in recent years, through the sowing of Subterranean Clover and various grasses with manurial dressings, a transformation has taken place, and we see it to-day devoted almost entirely to improved pastures and livestock.

One is here reminded of wise words spoken by our Director, Professor Perkins, before pasture improvement or top dressing was seriously attempted in this district. Unimpressed by the possibilities of successful wheat growing, we were told that our farms eventually must be converted into livestock propositions with pasture development. Wise counsel indeed, and surely Kybybolite must remain among the most pleasant recollections of his efforts that he carries with him from office. Efforts that I am sure every producer in the State is ready to acclaim.

I am indebted to Mr. Cook, the Manager, for statistics showing the development that has taken place since 1921, when pasture improvement was first undertaken. To simplify, it is set out in 5-year periods as follows:—

Sheep.

Period.	Av. No. Carried Per Annum.	Av. No. Ewes Mated Per Annum.	Av. Annual Wool Production. Lbs.
1921-26	592	338	3,496
1926-31	1,057	490	7,802
1931-36	1,587	768	13,131

At present there are 1,800 sheep on the farm and nearly 1,000 ewes mated.

BIG STOCK.

Period.	Av. No. Cattle Carried Per Annum.	Av. Annual Cream Production. Lbs.	Av. No. of Horses.
1921-26	68	10,342	35
1926-31	108	21,062	34
1931-36	137	23,136	24

For the period 1935-36 the Farm carried 147 cattle, 22 horses, and produced 26,430lbs. of cream. These figures speak for themselves, and show that to-day the property is in a very high state of production.

To the visitor unaccustomed to the sight of highly-improved pastures our Farm presents—particularly in the spring months of the year—an impression that we are nearing the millenium. I plead guilty myself to such an impression when first I saw the magical combination of Subterranean Clover and superphosphate. In fact, one hears not infrequently—from unthinking people, I admit—that our Farm has done all it can, and has outlived its usefulness. To the writer, however, it has not commenced to live. The title of this paper is "Our Experimental Farm." I look forward to the day when it shall be known as the Kybybolite Research Farm, equipped with a complete staff of highly-qualified research workers.

I know these remarks will be received with derision by some, but those experienced in pasture development and with an appreciation of the potentialities of the South-East and other vast areas in the southern coastal regions of the Commonwealth, will realise the urgent need for more intense research work, and it is with this hope that I contribute this paper.

The Health of Livestock.

A great deal of useful and interesting experimental work in pasture improvement is being carried out at the Farm at the present time, but the full value and the greatest value of these experiments—I refer to nutrition and health of stock—cannot be determined because of the lack of facilities thoroughly to test out the experiments.

It is a known fact that quite a number of landholders are retarding the development of their properties because they fear, rightly or wrongly, the introduction of fresh ailments to their stock.

That the running of 4 or 5 sheep where one previously grazed will bring some trouble is only natural, but the gains from pasture improvement so outweigh the losses that we are not going to revert to the old conditions; for it has been the writer's experience that for every sheep lost on our clover pastures 10 died for want of it. Nevertheless, we must admit that troubles do exist, and will increase with the heavier stocking which is bound to continue.

The question of liming and its bearing on the health of stock is in my opinion one requiring urgent investigation; in fact, this question is becoming an obsession with the writer.

Knowing our soils to be deficient in calcium, a certain amount of experimental work with lime has been done on the Farm, but only as it affects plant production, and results show its use at present prices to be uneconomical. But its value in regard to health of stock—probably where its real value will be found—has never been tested. I feel convinced that lime in the manurial treatment of our pastures will become an essential factor in the healthy development of our stock.

In a recent issue of a leading Victorian weekly, there appeared in its agricultural columns a report on pasture improvement on a well-known grazing property in that State, and it is the assertion of its owner "That since he adopted the use of lime in conjunction with superphosphate as a manurial dressing there has not been a case of milk fever, mammitis, or any other disease among dairy cattle, or an infestation of sheep or cattle with animal parasites." A remarkable assertion, sufficient to make us urge for a more thorough investigation into the use of lime in the manurial treatment of pastures in these parts of our State.

If our Farm could establish the claim of this Victorian landholder it would not be difficult to imagine the benefit this district alone would derive.

The cash value of experimental or research work is inestimable; though I do remember when Federation wheat, for instance, was first introduced into Victoria —it was estimated that the increased yield obtained from this variety was worth £200,000 per annum to the wheatgrowers of that State.

Recent Wheat Crop Competitions in this State show Roseworthy College bred wheats to be well in the front of the prolific yielders. If the cash value of these increased yields could be computed and credited to its rightful source, Roseworthy College would show some handsome balances.

Who could place an estimate of the increase in wealth in our own State, or even in our own district, due to the advent of superphosphate, the result of scientific research?

We seem ever ready to avail ourselves of the material advantages and comforts that science has handed to our civilisation, but seldom to realise or express appreciation of the wealth it pours into the lap of the community. Should we not urge, then, for an extension of this work at our own Farm, the need for which is so apparent?

Truly much helpful laboratory work is being done, and I do not wish to detract from or underestimate the value of the work of the analytical chemist, but one does wonder at times if we are paying a little too much regard to high nutritive values in our pasture plants and overlooking something either in lower values or manurial treatment that might better the health of our stock. Only field tests can ascertain this, and we must rely on our research workers for such help.

It is interesting here to note that the question of nutrition is a matter of world-wide concern to-day. Our own High Commissioner, Mr. Bruce, as readers of our leading dailies will observe, has appealed to the League of Nations for the co-operation of all countries towards the realisation of the ideal of "marrying health and agriculture." Mr. Lyons promises an inquiry, and says Australia will not be behind other nations in investigating her own conditions and contributing to the general knowledge.

Considering that the human and animal structures are built and sustained by products of the soil, such an inquiry should have far-reaching effects, not only in a material sense, but in the more important aspect of its bearing on the health of the community.

Agricultural Research.

One does not have far to look to realise that Australia lags far behind other countries in its agricultural research work. Compared with South Africa, the sum spent on such work is infinitesimal, while our own State spends only a fraction of that spent by Victoria, though South Australia depends to a far greater extent on its primary industries. Yet it is pleasing to note that our own Experimental Farm is in the van so far as pasture work is concerned, and its work seems to be of a more practical nature than that of similar institutions in Australia.

The fact that its work is published in leading scientific journals overseas, and inquiries are received from some of the leading farming countries of the world regarding its experiments, is evidence of growing interest and appreciation of its work. A glance at the visitors' book reveals the names of many interstate visitors, and not a few from overseas, including Downing Street. The high percentage of Victorian visitors is noticeable, and a great deal of interest is manifested by Western District landholders in particular. To those of us familiar with the southern portions of the State of Victoria, this is not surprising, for conditions there, generally speaking, approximate very closely to our own in relation to soil and rainfall.

As great as the influence of our Experimental Farm will have on the development of pastures in the South-East, one sees an even wider sphere in that wonderful stretch of country embracing practically the southern half of Victoria; in fact, one could include similar areas in New South Wales and Western Australia where Subterranean Clover is being used in the development of pastures.

The writer believes that this clover will be recognised as the basic plant in all pasture development in the major portion of the areas mentioned, especially on soils showing a calcium deficiency.

Now this raises the question whether in view of the wide sphere of influence of our Farm the cost of maintaining such an institution should not be contributed to by other States receiving benefits from its work, though the writer contends that it should be established as a National Research Farm backed by the Commonwealth Government.

In view of this Government's attitute toward the nutrition problem, I think immediate steps should be taken to have it established as such, and a strong case could be presented for the following main reasons:—

1. Its adaptability to practical field work.

2. Its approximation to soil and seasonal conditions of a tremendous area of the southern coastal country of the Commonwealth where pasture improvement is gradually developing.

3. The valuable data already collected through its experimental work gives it a long lead over any other institution of its kind in Australia.

To me the stage is set at our Experimental Farm for the expansion of research work of great national importance—work that is urgently needed, because I believe that to-day our advanced pasture men have got ahead of the scientists. I mean that he has brought his pastures to such a high state of productivity through the use of superphosphates alone that he does not know where to look for help in the troubles that have come in its wake, and we look anxiously but in vain for such assistance merely because of lack of research work being done.

Truly the farmer can do a certain amount of experimental work for himself, but he cannot get far without the research worker, and as a close observer of our Experimental Farm I should like to see it devoted to this work entirely.

I wish my remarks not to be construed as criticism of the management of the Farm under Mr. Cook, but would like here to express appreciation of his ability and keenness for his work which is outstanding in Australia to-day. I do criticise the limitation of the scope imposed on our Farm through lack of funds and facilities more thoroughly to carry out his important work.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April, 1935; to 30th April, 1936.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal, 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 31st March, 1936.	No. Eggs Laid Month of April, 1936.	Total Eggs Laid 1st April, 1935, to 30th April, 1936.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on 28th April, there being present:—Hon. A. L. McEwin, M.L.C. (Chairman), Messrs. J. W. Sandford, S. Shepherd, J. B. Murdoch, A. J. Cooke, F. Coleman, H. N. Wicks, P. J. Baily, Professor A. J. Perkins (Director of Agriculture), and H. C. Pritchard (Secretary).

Apologies were received from Messrs. A. M. Dawkins, G. Jeffrey, and Dr. Richardson.

Congress, 1936.—The Secretary was instructed to seek approval for the holding of the 1936 Congress. The Chairman, Vice-Chairman, Messrs. A. J. Cooke, H. N. Wicks, and the Secretary were appointed as a Committee to supervise arrangements.

Approval was given for the formation of Branches at *Cambrai* and *Owen* (*Women's*) and the re-organisation of the *Meadows* Branch, with the following as foundation members:—Cambrai—R. Miller, R. Hutton, D. H. Hutton, R. L. Hutton, K. Royal, L. Royal, D. Brophy, K. Brophy, F. W. McGorman, J. Starick, R. H. Pietsch, B. H. Braunach, H. Liersch, L. Haydon, A. T. Schultz, C. Schultz, E. H. Schirmer, G. B. Payne, B. H. Mickan, J. Baker, H. Mickan, F. W. Fiegert, H. F. Stevens; Meadows—G. Joyce, A. K. Surridge, L. A. King, E. Portlock, E. G. Mitchell, J. Turner, J. J. Teague, J. F. Smith, G. W. Bignell, F. J. Buck, H. C. Stacy, H. G. Egarr, W. C. Sickert, R. Bartley, C. R. Wharton, E. W. Young, J. F. E. Bensch, F. W. Gage, J. J. Devlin, J. M. Lawton, R. J. Underdown, J. J. Lomman; Owen Women's—Mrs. W. J. Marshman, Mrs. O. E. Hancock, Mrs. H. Moeller, Mrs. J. I. Williams, Mrs. E. S. Hancock, Mrs. H. Bradley, Miss M. Lake, Miss D. Jeffrey, Mrs. H. Helps, Miss G. Hancock, Miss D. McFarlane, Miss M. Helps, Miss D. Moeller, Mrs. T. L. Dunstan.

In the case of the Meadows Branch, the Secretary reported that this Branch had applied for an exemption from payment of *Journal* subscription fees, as had been granted other similar settlements in the Hills districts. This was agreed to, and the Secretary was instructed to ask the exemption for a period of 12 months.

Branches to be Closed.—The Board decided to close the North Booborowie, North Bundaleer, and Naracoorte Branches.

New Members.—The following names were added to the rolls of existing Branches:—Allandale East—A. W. Earl, Wm. L. Laslett, Gordon Thompson; Arthurton—H. J. Cadd, Ross Henderson; Balhannah—K. Robinson, W. Prosser, T. E. Grivell, J. Morris; Beetaloo Valley—Hurtle Sanders, Clem Giddings; Carey's Gully—S. Horsnell; Frayville—B. O. Kubenk; Green Patch—Colin Stephens, Geoffrey Pope, John Pope; Hilltown—Stan Sawley; Longwood—J. C. Dunstan; Maltee—Leslie Higgins; Mount Barker—T. G. Symonds, A. C. Hinton, J. F. White; Narridy Women's—Mrs. R. Smart; Nelshaby Women's—Mrs. L. E. Neagle; Penola—R. R. Rymill, Alan McDonald, E. Walsh, N. J. McBain, G. Clifford, M. Ricketts, M. Kidman; Petina—L. C. Kaehne; Pinnaroo Women's—Mrs. Teschendorf; Shoal Bay—Ronald Schaefer; Strathalbyn Women's—Mrs. A. Garbutt, Mrs. J. Stanton; Sutherlands—L. O. Worrall; Tantanoola Women's—Mrs. A. Jordan, Mrs. J. Kennedy; Tatiara—E. J. Buckley; Ungarra—A. R. Butler, F. C. Telfer; Watervale—Rex Glaetzer; Yandiah—Douglas Stirling, E. C. Michael, R. Llewelyn.

Retirement of Professor Perkins.—The Chairman, in informing members that this was the last meeting which Professor Perkins would attend as an official member of the Board, made reference to the long and active association that the Director had had with the Board, and with the agricultural activities of the State. The Director took with him the best wishes of the Board, and the appreciation of members of the services that he had rendered to the primary producers of the State. Each member present also spoke.

On the suggestion of Mr. Baily, it was decided that the Minister should be asked to recognise the Director's work by appointing him a life member of the Board.

Recognition of the Director's Services by Agricultural Bureaux.—The Secretary read a letter from the Sandalwood Branch of the Agricultural Bureau, suggesting that some action should be taken by Branches of the Agricultural Bureau to show their appreciation of the services rendered to the primary producers of the State by the Director. The Secretary was instructed to take preliminary steps to give effect to the suggestion of the Sandalwood Branch, and, when communicating with Branches, to ask for suggestions as to what form any presentation that might be made should take. A letter of appreciation of the work of Professor Perkins from the Inman Valley Branch was also read, and the Secretary was instructed to forward it to Professor Perkins.

Several items were taken in Committee.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. Sandford & Co. Limited, reported on 1st May, 1936:—

Butter.—Production during April was very disappointing as, except for a light to moderate rain received in some parts, the month was fairly dry. The feed which had germinated was badly needing additional rains and until the pastures are more forward there can be little improvement expected in butter production. Throughout the month there was a shortage of choicest grade so that it was necessary to obtain consignments from the eastern States to augment supplies. The London market showed some improvement at the latter end and the rate at present is 87s. per cwt., and local values are:—Choicest creamery fresh butter, in bulk, 1s. 4¼d. per lb.; prints and delivery extra. (This price is for local sale only, and under the quota system, the equalised price manufacturers will receive will be 1s. 0¾d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines from 1s. to 1s. 1d. per lb. for choicest; stores, 8d. to 9d. per lb. (These prices are subject to equalisation levies.)

Cheese.—In the Mount Gambier districts conditions have been drier than for 70 years past, and consequently, the tonnage turned out has fallen back considerably. However, there was enough available for local and Westralian trade, although exporting overseas has now ceased. Values were without change, being:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. to 1s. 1d. per lb.

Eggs.—As is usual in the cold weather the supplies of eggs have declined, and as there was a strong demand maintained, values firmed throughout the month. Rates in the eastern States were much firmer and this also had an influence on the local market. Present values are:—Ordinary country eggs, fair average quality, from 1s. per dozen net; selected new laid clean eggs, full-sized, to 1s. 5d. per dozen net.

Bacon.—As the supplies of live hogs kept up well, curers were able to supply the markets with ample quantities of bacon from week to week. There was a hardening in rates but this did not affect the sale, and turnover was well maintained. Hams, however, have been difficult to quit owing to the heavy surplus stocks offering. Values are:—Best quality sides, 10d. per lb.; middles, 10d. to 10½d.; heavy middles, 9d.; rolls, to 8½d.; hams, 11d. to 1s.; cooked, 1s. 2d. to 1s. 2½d. per lb.; lard, bulk, 6d. to 6½d.; prints, 7½d. per lb.

Almonds.—Trading in most lines was well maintained, although at the end of the month the interstate inquiries were disappointing and a lull in sales was recorded. This was expected to be only temporary, however, and, therefore, rates were unchanged. Kernels, however, were in good request and sold readily at quotations:—Softshells and Brandis, 8½d. to 9d.; hardshells, 5d. to 5½d.; kernels, 1s. 9½d. to 1s. 10½d. per lb.

Honey.—With the setting in of colder weather the sale of honey showed a little improvement, but stocks were not materially reduced and some outside overseas markets are urgently needed to reduce the surplus. Rates are:—Prime quality clear extracted, 2d. to 2½d.; lower grades, 1d. to 2d. per lb.

Beeswax.—Was in moderate supply, but much heavier quantities could have been placed. We advise consigning. Quotations are:—1s. 2d. to 1s. 2½d. per lb., according to quality.

Live Poultry.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms. The quantities handled in our sale rooms this month were heavy, but there was a large attendance of buyers at each of the auctions, and all classes of birds submitted readliy changed hands. We could dispose of greater quantities, and have special facilities for displaying the birds for buyers' inspection. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. to 4s.; nice conditioned cockerels, 2s. 4d. to 2s. 10d.; fair conditioned, 1s. 8d. to 2s. 2d.; chickens, lower; heavy-weight hens, 2s. to 3s.; medium hens, 1s. 7d. to 1s. 11d.; light hens, 1s. 2d. to 1s. 6d.; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. to 3s. 9d.; young Muscovy ducks, 1s. 8d. to 2s. 3d.; ordinary ducks, 1s. to 1s. 9d.; ducklings, lower; geese, 2s. 8d. to 3s.; goslings, lower; turkeys, good to prime condition, 8½d. to 10d. per lb. live weight; turkeys, fair condition, 7d. to 8d. per lb. live weight; turkeys, poor and crooked breasted, lower; pigeons, 3d. to 5d. each.

Potatoes.—New season's, 9s. 6d. per cwt.

Onions.—Brown Spanish, 11s. per cwt.

COMING SOON—A NEW
"CATERPILLAR" DIESEL FARM
TRACTOR—THE "RD4."

Smaller than any of the Diesel tractors that have, until now, been included in the "Caterpillar" line, the "RD4" extends Diesel economies to new thousands of power users.

Let us send you particulars of this new model which marks another important advance in "Caterpillar" leadership.

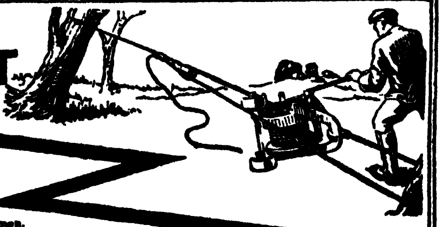
The popular Models "Twenty-two" and "Thirty" (for kerosene) will continue as at present.

Illustrated Catalogue posted with pleasure. Address your letter—

THE S.A. TRACTOR COMPANY,

Box 524E G.P.O., Adelaide. Showrooms : 231, Flinders St., Adelaide.

THERE IS ONLY ONE "CATERPILLAR.."



TEARING THEM OUT

is the regular job of the Monkey Grubber: in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barn truck, and worked in the same manner as a boat is rowed. It develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

Patentees and Makers—Monkey Grubber, Monkey and Wallaby Jacks:
TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC., AUSTRALIA.

ROSEWORTHY AGRICULTURAL COLLEGE

AFFILIATED WITH THE UNIVERSITY OF ADELAIDE.

GOVERNING COUNCIL:

A. M. DAWKINS, J.P. (CHAIRMAN)

F. COLEMAN, J.P. A. E. V. RICHARDSON, M.A., D.Sc.
L. T. COWAN, B.Sc. PROF. A. J. PERKINS
D. A. LYALL, ESQ. W. J. ADEY, ESQ.

H. C. PRITCHARD, A.F.I.A. (SECRETARY)

PRINCIPAL:

DR. ALLAN R. CALLAGHAN.

A thorough and well-proportioned course of instruction in the theory and practice of General Agriculture, including Viticulture and Oenology, as well as all phases of Livestock Husbandry.

The Diploma Course includes three years of class-room tuition and practical work, and carries the academic distinction of R.D.A.

Excellent opportunities offered for the training of boys of 16 years of age or over. Splendid food and accommodation, hot and cold water. Ample sporting facilities, gymnasium, sports oval, tennis courts, and swimming pool.

FEES.—£50 per annum, which covers board and lodging, instruction, medical fee and dispensary expenses.

SCHOLARSHIPS.—Six scholarships are open for competition annually, each valued at £136 10s.

Write for further particulars, and prospectus, to—

BARLEY

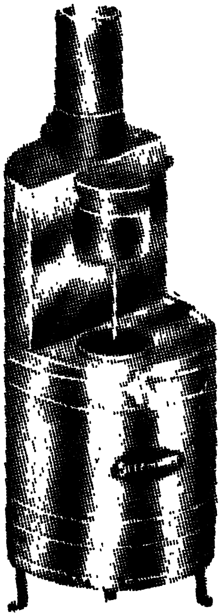
We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

F. W. HANCOCK & CO.,

CRANBROOK CHAMBERS, BENTHAM STREET, ADELAIDE.

TELEPHONE: CENTRAL 4855 and 4856.



The "Steemway" Steriliser.

DAIRY FARMERS

The "STEEMWAY" Steriliser is here.

It gives complete STERILISATION TO ALL DAIRY UTENSILS.

NO DELAY

In 15 minutes a continuous and plentiful supply of boiling water is available for any purpose.

ECONOMY. Low operation cost, specially designed to work on either Fuel Oil, Diesoline, Power Kerosene, Wood or Chips.

Write to the Sole Agent:

H. & C. F. CLUTTERBUCK,

61, Hindley Street, Adelaide.

THE "HOME" TRAIN.

Work over for the day, man and maid, young and old are intent upon "getting home." All day they have been concerned with business, mostly someone else's business, for the majority of the homeward-bound travellers are salary or wage earners.

Have they—have you—found time for personal business.

The Commonwealth Savings Bank is open all day in City, Town, Village and Country Post Office, and its convenient services are therefore easily available to all.

Opening a Savings Bank account—and using it—costs little time and no money, and it will pay you well in the long run.

Commonwealth Savings Bank of Australia

(Guaranteed by the Commonwealth Government.)

There is only One Best
SEPARATOR
THE
"ALFA LAVAL"
Holds the

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from 1st August, 1934, with the following exceptions:—Life members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

Services of Geologist.—The Director of Mines has intimated that it has been decided by the Government that, in future, a charge of £2 2s. must be made for the services of a geologist who selects sites for wells or boreholes on small holdings, and that a larger fee must be charged where larger areas are examined geologically for this purpose.

MEN'S BRANCHES.

WHEAT VARIETIES SUITABLE FOR THE TATIARA DISTRICT.

[Address given by Mr. E. S. Alcock, R.D.A., Agricultural Instructor for the South-East, before the Wolseley Branch of the Agricultural Bureau.]

A perusal of the list of varieties in Australia shows that varieties which are grown to any extent are those which have been raised in the Commonwealth. Wheats which have been introduced from time to time have been used for cross-breeding, and the results of the work of the respective Departments of Agriculture are being carefully watched by progressive growers in the various States in order to give a trial to any promising varieties. According to the Government Statist, nearly 200 varieties of wheats are grown in South Australia, and it might be said that many of these could be discarded on account of yield. The number of varieties grown in the Tatiara district is not, however, very large, but nevertheless, the total production of the district would be improved by the more general use of more suitable wheats.

Improvement in Quality.

Much dissatisfaction has been lately heard in regard to the quality of Australian flour, and although the grower might state that this is the concern of the miller, there is another aspect to be considered. If the primary products of Australia are to be placed on the world's markets, they must be such that will find a ready sale. If the goods offered to a buyer are what he wants, he will pay the seller's price, but if the seller offers him something which is not up to the standard of his requirements, the buyer takes it at his own price. Experience has shown that those varieties of wheat which produced strong flour were poor yielders, and were, therefore, not favoured by wheatgrowers. The Wheat Improvement Committee in South Australia has recommended the following varieties for general planting in this State:—Aussie, Canberra, Crossbred 53, Currawa, Dundee, Federation, Felix Ford, Gluyas, Late Gluyas, Minister, Quality, Ranee, Sword, and Nabawa. The Committee has strongly urged that the following varieties should no longer be grown:—Free Gallipoli, Gluclub, Waratah, and Ghurka.

In 1925, Federation represented 75 per cent. of the total wheat sown in Victoria, Huff's Imperial 8 per cent., Penny and Major 4 per cent., Dollar and Wannon 2 per cent. In 1934 Free Gallipoli had displaced Federation and represented 57 per cent. of the wheats in Victoria, Ghurka 21 per cent., Ranee 9 per cent., Nizam 3 per cent., Federation and Wannon 2 per cent. In South Australia Free Gallipoli held third position in the list of the most popular varieties. During the seasons 1932, 1933, and 1934, 300,000 to 400,000 acres were sown to this variety. In New South Wales it was the fifth most popular wheat in 1934 and eleventh in Western Australia. It was claimed that Gallipoli increased the yield by 2bush. per acre. This variety would still have been the most popular in this district had not a ban been placed on it on account of its poor baking qualities. At Salisbury (Victoria) where the soil conditions and climate are somewhat similar to those in the Tatiara district, the undermentioned varieties gave the following results for four seasons (1931-1934):—Ghurka (39bush.), Gallipoli (35.3), Mogul (34.6), Rajah (34.6), Nizam (33), Ranee 4H (32.5), Federation (30.4). Mr. J. Brake (Agricultural Superintendent), speaking at a Field Day recommended Ranee 4H which, he said, had done well in Departmental tests in Victoria.

In another series of trials over four years, earlier than the above, the results were as follows:—Gallipoli (28.1), Rajah (29.1), Ranee 4H (26.7), Mogul (27.1), Federation (24.9).

Wheat varieties have been sown on Mr. W. Gill's property at Keith, and the results (1928-1932) were—Bena (20bush. 43lbs.), Sultan (18bush. 52lbs.), Dan (16bush. 46lbs.), Federation (16bush. 37lbs.), Major (16bush. 24lbs.); and for 1930-33—Federation (15bush. 37lbs.), Gallipoli (19bush. 25lbs.). From these figures, Bena, Gallipoli, and Sultan show the best results for this locality. Whilst on the heavier land Ghurka and Gallipoli, followed by several varieties which have never been popular in this district, except Nizam and Ranee 4H.

VARIETIES WORTH CONSIDERING.

Since Federation yielded so well in this district, it is desirable to look at those varieties which have Federation strain in them. The main reason why these Federation strains are so popular here is because they are short-strawed and do not grow rank like so many other varieties are inclined to grow on heavy land.

Federation was bred by crossing Purple Straw with Yandilla King, Ranee (Federation x Indian F), Dundee (Hard Federation x Cleveland) x Sands, Union (Federation x Nullah), Duchess (Federation x Minister), Ghurka (Indian H x Federation x Currawa), Gallipoli (Club x Yandilla King), Nizam (Indian F x Federation), Mogul (Indian F x Telford's), Rajah (Indian F x Telford's), Bena (Hard Federation x Marshall's), Sultan (King's White x Caliph), Dan (Daphne x Fan), Major (Federation x Wallace).

Ranee 4H.—This variety is increasing in popularity. It was the fourth most popular in 1932 and has been second in the list for the last three years and for 1934-35; 14.31 per cent. of the total area sown in this State was Ranee (495,175 acres). In other States it is increasing, and in New South Wales it is said to be displacing Nabawa. It is, however, subject to rust and Flag Smut.

Dundee.—A New South Wales bred wheat which is now on trial. It grows a medium height, with strong straw, holding its grain well, and stands up better than Gallipoli. Gluten quality is good. Resistant to Flag Smut but subject to rust. It is worthy of a fair trial in this district because it is reported to do well where Federation is popular.

Duchess.—Said to be of medium height wheat, producing excellent grain of good milling quality, but owing to straw weakness and liability to disease, despite holding its grain well and also yielding well in favourable seasons, this variety is not likely to be very popular.

Ghurka.—A Victorian variety which is gaining popularity on account of high yielding ability in that State. It yields well and resists disease very well, but is not recommended for general sowing in this State on account of its low flour strength.

Nizam.—This dark-chaffed club-tipped variety has been grown in this district and has yielded quite a lot of grain in favourable years, but as it is subject to rust and flag smut, is not likely to be largely grown.

Mogul and Rajah.—These two Victorian varieties claim the same parents, but are quite different in appearance. Neither have very much to recommend them.

Bena.—This variety was given a trial here some years ago, but it did not give sufficient promise and is not grown now. It is subject to both rust and Flag Smut.

Sultan.—This Roseworthy variety has not found favour in this district because of its tendency to lodge. It is much more suitable for the light mallee soils.

Dan.—This variety did well at Keith, and was also tried out at Millicent, but grew too tall.

Major.—This variety was grown here some years ago, but made too much growth of straw, but yielded well. It is now grown in the lower South-East, and yields well unless there is too much rust.

Bencubbin (Gluyas x Nabawa).—This variety was bred in Western Australia, where it is the most popular wheat. White chaffed and holds its grain well, and also has the power of crowding out weeds, but its weak straw and tall-growing habit will not make it very suitable for this district despite the good yields. It is now on trial in the district.

Baringa (Gullen x Bomen).—Raised in New South Wales. A white-chaffed wheat earlier ripening than Gallipoli, hard to thresh. Susceptible to rust. Has been very successful in New South Wales. A little has been sown, but does not seem to be favoured by many.

Baldmin.—Bred at Dookie, Victoria. A medium strong wheat, which has yielded well at Dookie. Rather weak in the straw and inclined to lodge. Has been tried, but not very successful here.

Ford (Fan x Comeback x Tardent's Blue x Zealand).—This Roseworthy College variety is very disease-resistant, especially to bunt. It is now well known and making great progress in New South Wales as well as outside the Commonwealth. When grown in this district, it grows rather tall, and being a white-chaffed wheat, is not as popular as some other varieties. Has been used by Roseworthy College to check the variations which occur in the different parts of the State regarding flour strength.

Sword.—Bred at Roseworthy. This variety was grown in the district after its good performance at Roseworthy, and in other parts of the State. It was inclined to grow too tall and did not yield as well as the more popular varieties in this locality.

Minister (Dart's Imperial x Fife-Indian x Dart's Imperial).—This variety was grown in the district some time ago, and yielded well with some growers. A bonus was paid by some millers for this grain. Susceptible to rust and Flag Smut.

Resistance to Disease.

This district does not suffer badly from disease, when compared with some other districts in this State, but those that have been noticed are as follows:—

Flag Smut.—This disease has appeared in small areas in several paddocks, and it is only occasionally that it makes a serious effect on the yield. The heavy rainfall must help to pack the soil and form a compact seedbed, thus helping to control this disease.

Take-all.—This disease like Flag Smut, does not take any serious proportions in this district, unless the seedbeds are exceptionally loose.

Loose Smut.—This is easily the worst disease in the district, and must be responsible for considerable reduction in the wheat yields annually. More care is needed in the selection of seed in order to reduce the severity of this disease. No easy method of prevention is available, as the spores of this fungus are located inside the grain. The only treatment for control is rather cumbersome for the farmer, because it is necessary to immerse the wheat in hot water for a considerable period and, at the same time, to keep the temperature fairly consistent or else the grain will not germinate.

Bunt or Stinking Smut.—This disease is so well known and well under control that it is seldom seen in the Tatiara district.

Rust.—This is a seasonable disease, but it does not do the damage to wheat crops as in the early days. Nevertheless, unless care is exercised in sowing only varieties that are not susceptible, the yields in some years will be greatly affected.

Eel Worms.—These small insects do quite a lot of damage to cereal crops in some soils, especially where the seedbed is left open and loose, and also in fields that have been over-cropped.

● FULL MOON

SUMMARY.

Sow only varieties which are suitable for the district—those which have yielded well and are recommended from districts similar in climate and soil. Give some attention to quality as well as quantity, because buyers judge the produce on quality.

Varieties which might be worth trying:—Ranee 4H, Dundee, Union, Duchess, Dan, Baringa, Bencubbin, Sword, Minister, Nizam, Ford.

Give some consideration to the resistance of varieties to various diseases such as Flag Smut, Rust, and select seed free from Loose Smut.

BALHANNAH AGRICULTURAL BUREAU SHOW.

The second competitive show organised by the Balhannah Agricultural Bureau was held on Saturday, 28th March, and the increased number of entries and better quality were evidence of the interest aroused. Bureau members hope to enlarge the show into a full-sized agricultural event for the autumn, and already are looking for a show ground. The classes on this occasion were restricted to indoor sections, but in a few years the Balhannah event should be the equal of any of the Hills shows.

The show was opened by Mr. Playford, M.P., and Messrs. Morphett, M.P., and Young, M.L.C., also spoke. A vote of thanks was moved by Mr. H. N. Wicks (Advisory Board of Agriculture). Mr. E. W. Mattner supported him.

"The export apples were excellent, and if all those sent overseas were of equal quality there would be no complaints," said the judge (Mr. E. Leishman). "The pears and other apples were of outstanding quality, but competition was poor."

The vegetables were judged by Mr. Bert. Gore, of Piccadilly, who said that the standard was extremely high. Cabbages, cauliflowers, and carrots were outstanding, while the potatoes, onions and peas were particularly good.

Mr. W. Hughes, of Unley, judged the flowers, and was very favourably impressed by their quality. The roses were excellent for the time of the year, and he commented favourably on the other classes.

Mrs. I. Park judged the preserves, cookery, and needlework, which was generally of good quality, while she was particularly impressed with the jams and jellies.

CROP COMPETITIONS IN THE SOUTH-EAST.

PRESENTATION OF TROPHIES.

"My recent trip to New Zealand has more than ever convinced me of the almost unlimited agricultural and livestock possibilities of the South-East, and that with proper development the South-East will, in the future, support as many people as the whole of the other rural areas of South Australia—this future may not be as far distant as we think."

This statement was made by Mr. L. DeGaris (Mayor of Mount Gambier) in the course of an address on the occasion of the presentation of prizes awarded in the Mount Gambier Agricultural Bureau and Agricultural Society's Annual Crop Competitions in the local town hall on Thursday, 23rd April. Continuing, Mr. DeGaris said New Zealand exports amounted to approximately £50,000,000 each year, 91.4 per cent. of which was derived from her pastoral industry. Normally, every acre under cultivation returned £3 in exportable produce every year. He made reference to the valuable investigational work which was being carried out at the Kybybolite Experimental Farm. The Lincoln College at Christchurch comprised an area of 1,000 acres, and was supported by private endowments, Government subsidies, and donations from farmers and millers' associations. The farmers gave 1½d. per bushel on the whole of the crop they produced, and the millers subscribed a like amount on all wheat which passed through the mills. The scope of work of the College covered cereal breeding, stock raising, improving grasses. Although New Zealand grew only sufficient wheat to feed her own people, farmers received a guaranteed price of 4s. 4d. per bushel. The average wheat yield of New Zealand was 32bush. to the acre, 75 per cent. of the wheat being of the Tuscan variety. The object of the wheat-breeding experiments at the College was to evolve a wheat suitable to local conditions, and secondly, to produce a wheat with high milling qualities, at the same time maintaining the highest possible yields. This, said Mr. DeGaris, was one reason why the millers subscribed so willingly to the upkeep of the College. Speaking to Mr. Calder, who had charge of the grass and pasture experiments, the speaker had learned that the College advised a period of 6 months' fallow before laying down a paddock to pasture. South-Eastern graziers, Mr. DeGaris said, would have to pay more attention to the initial preparation of the land which was going to carry their grasses and clovers.

At the Massey College the South Australians had been particularly interested in the work which was being done in regard to hairiness in wool. This work involved the testing of every Romney Marsh stud flock in the Dominion. Mr. DeGaris believed that this was a field for research work in Australia which would pay for exploration. On being asked to make some reference to the lamb industry, the speaker said the fat lamb of New Zealand was practically a standardised form of produce. Practically all the lambs were by a Southdown ram from a Romney Marsh mother, and were remarkably even. The best lambs of the South-East, he believed, were better than those of New Zealand; the flavour of our lambs was definitely better. New Zealand's big advantage, however, was that something like 90 per cent. of their lambs were killed the same day that they were taken off their mothers.

Mr. L. J. Cook (Manager of the Kybybolite Experimental Farm) supported Mr. DeGaris in his remarks concerning the possibilities of the South-East. Pasture, he said, was the most important crop in the South-East. The district was using considerably more superphosphate than in the past, which was a good indication of the progress that was being made. Too many landowners, however, were prone to thing that top-dressing was the beginning and end of pasture management. There was a much bigger lesson to learn than that. The crowding of large numbers of stock on comparatively small areas had already brought in its wake diseases which they previously had not encountered. They need not, however, be unduly dismayed. Research work was already in hand, and was meeting with success.

Mr. DeGaris had referred to the production of £8 per acre from New Zealand pastures. There were many fields on the Kybybolite Farm that had carried 3 ewes and 3 lambs to the acre—the lambs being sold for 15s. and the wool from their mothers, 14s.—the returns per acre being in the vicinity of £4, and there were thousands of acres in the South-East now lying idle capable of giving those figures. He agreed with Mr. DeGaris that fallowing in preparation for laying down of a pasture would give best results.

Mr. DeGaris made the following presentations:—Barley Section—First prize, D. A. Norman; Second, A. H. Allen. Pastures—First, C. T. Major; Second, F. C. Caine. Oats—First, L. H. Patzell; Second, F. W. Button. Maize—First, J. T. Carthew; Second, J. Hyde. Messrs. S. Shepherd (Advisory Board of Agriculture) and F. C. Richards (Asst. Secretary, Agricultural Bureau) also addressed the meeting. An excellent programme was provided by Mrs. Reid's and Mr. Prime's orchestra, Miss McPherson, Mrs. A. Williams, and Miss E. Dodd. Mr. C. T. Major presided.

POTATO COMPETITION—MOUNT COMPASS SCHOOL BOYS.

[H. H. Orchard, Horticultural Instructor.]

For the fifth year a potato growing competition for boys attending the Mount Compass school was conducted by the local Branch of the Agricultural Bureau. Each boy receives 1lb. of seed, and, in the presence of stewards appointed by the Branch, cuts the tubers (this year 10 in number) into as many sets as he desires, and plants them as he thinks best. The allotment of seed, cutting and planting, and later on the digging of the crop are closely watched; other operations, such as the preparation of the land prior to planting, subsequent treatment, and the use of fertilisers are left to the discretion of the landowner. The prinicpal prize goes to the boy who digs the highest yield. This year Messrs. Pitt Bros., of Ashbourne, kindly donated selected Carmen seed of their own growing, and the results obtained by the boys must be very gratifying to the donors, who, in addition, presented the prizes for the competition.

Cutting and planting was done on 29th October, 1935, and the number of sets obtained from the 10 tubers supplied ranged from a minimum of 34 up to a maximum of 92, the average being 57. The plots were dug on 12th March, 1936, with the following results:—

Yields of Potato Competition, 1936, *Mount Compass School Boys.*

Competitor.	Sets Planted.	Sets Shot.	Sets Dug.	Yield. lbs.
Linton Jacobs	92	91	90	438
Don Jacobs	67	61	61	294
Ben Peters	40	40	40	281
Fred Dreyer	45	45	45	207½
Kelvin Peters	39	37	37	170
Douglas Chigwidden.. ..	89	85	85	152
Sam Miller..	37	37	32	139½
Laurie Garden	34	32	32	118½
Kevin Harris	63	63	63	95½
Harry Garden	35	33	33	78½
Brian Simons	85	60	30	63
Average	57	53	50	185¼

Average yield per set, 3.721lbs.

Altogether, 11lbs. of potatoes were planted, which yielded 2,037½lbs., or an average of 185¼lbs. of potatoes for every plot planted.

The previous record yield of 278lbs., established by Don McKinley in 1934, was easily broken this year by Linton Jacobs, and two other boys, Don Jacobs and Ben Peters, also exceeded the previous best.

Highest Yield from 1lb. of Seed Potatoes, Mount Compass School Boys.

Year.	Winner.	Yield. lbs.
1932	Kelvin Peters	108
1933	Linton Jacobs..	217
1934	Don McKinley	278
1935	Don McKinley	270
1936	Linton Jacobs	438

The average yield per set of the leading competitors is interesting, as the following table shows:—

Competitor.	Sets Dug.	Yield. lbs.	Average Weight per Set. lbs.
Linton Jacobs	90	438	4.87
Don Jacobs..	61	294	4.82
Ben Peters	40	281	7.00
Fred Dreyer	45	207½	4.61

The fertilisers used on the two leading plots comprised:—

	s.	d.
20lbs. blood and bone, estimated cost	1	6
20lbs. 48 super, estimated cost	0	10
10lbs. sulphate of ammonia, estimated cost	1	2
2 bags fowl manure	1	8
Total	5	2

The potatoes from these two plots were purchased by the donors of the seed at the ruling market price of 6s. per cwt., so that these two boys, for an outlay of 5s. 2d. for fertilisers, received 22s. and 18s. respectively.

When the foregoing figures are worked out on an acreage basis the following interesting results are obtained:—

Potato Competition, Mount Compass School Boys.

Competitor.	Area of Plot. sq. ft.	Yield. lbs.	Cost of Fertiliser per acre rate. £	s.	d.	Yield per acre rate. T.	c.	lbs.	Gross returns at £6 per ton. £	s.	d.
Linton Jacobs	480	438	23	5	0	17	14	100	106	10	0
Don Jacobs	441	294	25	10	4	12	19	97	77	15	9

The top growth, or growth of haulms, was remarkable in some of the plots, the heaviest amount from one set being 24lbs. on the prize-winning plot. The heaviest tuber was 3½lbs., dug by Sam Miller.

Most of the competitors dug good shaped, clean skinned tubers, with an absence of disease. At the local show, held two days after digging was completed, all the produce was exhibited, in accordance with the regulations governing the competition, and judged from a commercial point of view. This award finally went to Don Jacobs, after a close contest with Fred. Dreyer.

The two leading crops were grown in well-prepared black peat swamp land, and were watered three times with sprinklers during the season. The third crop was planted in a dark sandy loam, and was irrigated, and the fourth was in a heavy peat land, cropped for the first time after clearing.

Congratulations are extended to the boys on their splendid efforts, and to members of the Bureau, who have fostered an interesting competition for the boys.

POTATO GROWING—YUNDI SCHOOL BOYS.

[MR. H. H. ORCHARD (Horticultural Instructor).]

The Yundi Branch of the Agricultural Bureau conducted a potato growing competition for school boys along similar lines to the Mount Compass event, differing only in the allotment of the prizes. Chief prize went to the boy who obtained the highest yield of marketable potatoes, and other prizes were allotted to the second highest yield of marketable tubers and to the best sample.

The same seed as at Mount Compass, selected Carmens grown and donated by Messrs. Pitt Brothers of Ashbourne, was used. The results obtained are highly gratifying, especially when it is realised that two years ago the land was scrub.

Altogether 18 plots were planted but for various reasons the number was reduced to 12 at the time of digging and of this number, three could not be included because of extraneous circumstances greatly affecting the yields.

The winner proved to be Douglas Smith who planted and dug 67 sets and obtained 279lbs., representing 86.51 per cent. of the crop, of good, clean skinned, marketable potatoes. Sydney Guthridge was second with 214lbs., representing 77.25 per cent. of the crop, and Clyde Smith, an older brother of Douglas, a close third with 201lbs. with the good percentage of 86.27. The prize for the best sample was awarded to Harold Normandale. The following are the results:—

YIELDS OF POTATO COMPETITION, 1936, YUNDI SCHOOL BOYS.

Competitor.	Yield from 1lb. seed— Marketable.	Small and Inferior.
	Lbs.	Lbs.
Douglas Smith	279	43½
Sydney Guthridge	214	63
Clyde Smith	201	32
Harold Normandale	85	37
Douglas Marshall	62	23½
Ross McAlister	61½	45½
Keith Lomax	43½	22½
Max Sykes	34½	30
Frank Field	29½	45

The average number of sets planted per pound of seed was 60, and the average number dug 43.

Douglas Smith used bone-dust and fowl manure at an approximate cost of 3s. 10d.; Sydney Guthridge used blood and bone manure and fowl manure costing about 2s. 10d.; Clyde Smith used similar fertilizers at the same cost as his brother Douglas.

POTATO EXPERIMENTS AT CAREY'S GULLY.

At the April meeting of the Carey's Gully Branch the Chairman reported on the potato experimental plots carried out in his garden. Plots of one square rod were measured out on hill slope land typical of the district. Ordinary market garden methods of planting, cultivation, and irrigation were adhered to as nearly as possible. The plots were planted on 9th October and were dug on 16th March. Results are shown on the accompanying table. In discussing the results members considered that the mixtures generally recommended for potato growing were not suitable for the district, the results from the experiments confirming this opinion. Bonedust was the artificial manure most favoured, although a dressing of sulphate of ammonia after tubers were formed would probably have given even better results. Cow manure, if available in sufficient quantities, gave splendid results. The quantity used in the experimental plot was equal to a dressing of 32 tons per acre. The 2-2-1 mixture (super, ammonia, and potash) appeared to be worthy of further trial. The 2-2-1 plot was still fairly green at the time of digging, and gave the largest tubers, 14 weighing 28lbs. Twelve sets failed to come through, probably being burned by coming into direct contact with the fertiliser. A competition to produce the best crop of potatoes from a square rod of ground was suggested as a means of trying out a greater variety of manures, and was held over to the next meeting for consideration.

SOCIAL AT HILLTOWN.

Under the auspices of the Hilltown Branch a social was held on 16th April, when prizes won in the Midland District Wheat Crop Competition were presented. A splendid gathering resulted. Addresses were delivered by the Minister of Agriculture (Hon. A. P. Blesing, M.L.C.), Hon. W. G. Duncan, M.L.C., and Mr. W. J. Spafford (Deputy Director of Agriculture). The Hon. Minister presented trophies to the following competitors:—First—Mr. R. L. Sluggett, Hill River (93 per cent.). Second—Mr. P. McD. Smythe, Salter's Springs (91½ per cent.). Third—Mr. H. Schunke, Manoora (90½ per cent.). Fourth—Mr. S. Garrard, Mintaro (90 per cent.).

The prize donated by the Millers' Association for wheats other than Gallipoli, Ghurka, Waratah, and Nabawa was presented to Mr. R. L. Sluggett (Dan variety), with Mr. P. McD. Smythe (Ford) second. A special trophy for the cleanest crop (highest points in all sections except yield) was awarded to Mr. R. F. Thomas, Hallett (62.5 per cent.). A supper and dance followed. Thanks are due for the assistance given by the ladies.

CARE OF LIVESTOCK.

Paper by Messrs. T. A. Earl and C. N. Wallace, given at the Allandale East Branch meeting on 3rd April:—"*Horses.*—It is both wasteful and dangerous to feed hay loose to horses, as at this time of the year as well as in the middle of winter they tramp a lot into the ground, and in the dry weather, as they are picking around for the straws, they get a lot of dirt, &c., which is apt to cause digestive trouble, such as sand. Another common complaint among horses at this time of the year, when the hay is new, is colic, which is due to two factors. The horse relishes the new chaff, and bolts it without chewing it, and the moist, immature hay ferments more easily in the stomach, and causes an accumulation of gases. Wet or musty chaff will also cause colic. Horses should be well groomed in the morning to remove dirt and hair, especially on the shoulders. The skin cannot perform its functions properly unless it is kept clean. Shoulders and neck are liable to be chafed with the collar if grooming is neglected. Water horses regularly, and when a horse is over-heated allow him only a small quantity of water until he has cooled down. When working, always have the chains of equal length in order to avoid throwing undue strain on either shoulder. *Cattle.*—Dairy cattle, being more delicate than other farm stock, consequently need more attention. The cows should be kept in the best paddock available, and hand-fed during the winter months and dry periods. For green feed, if the rain comes early, barley makes good feed, but if the rain is late, oats are more suitable. A few acres of millet will greatly increase the milk production, and help to keep the cows in better health. It is advisable to feed hay or chaff during the winter months, as the cows relish some dry feed at this time. It is not necessary to feed during the spring, but as the feed goes off and one wants to keep up the milk supply, it is advisable to have a standby of summer fodder, such as maize, chou moellier, turnips, or mangolds. It is advisable, when feeding cows with chaff, to add a handful or two or bran and a small quantity of salt; also a quantity of Meggit's meal. A packet or two of drench should be on hand in case of sickness with stock. If there is not sufficient shade or shelter in a paddock it is a good plan to plant trees or shrubs. *Sheep.*—The Allandale land is more adapted to sheep raising than anything else. The most payable proposition generally is to raise lambs, either for fattening or for wool. It is always advisable to keep a good supply of coarse salt in the paddocks, as it keeps the sheep healthy, and aids digestion. Change the sheep regularly, and do not keep them too long in one paddock. Crutch sheep before the first sprout of green grass, preferably about the 1st of May. Ewes require the most attention at lambing time, because every lamb saved means at least 10s.

CARE OF FARM HORSES.

In the course of a paper read at the March meeting of the Booborowie Branch, Mr. H. Phillips stated:—"It is not a wise plan for farmers to breed the big, heavy stock for this district; the medium, "nuggetty" horse is preferable. This type of horse stands up to the work and conditions better, does more work in less time than the heavy horse, and requires less feed and water. As his livelihood largely depends on his horses, it behoves the farmer to give them reasonable care and attention. A good stable, warm in winter and cool in summer, will go a long way towards keeping horses fit and in good working condition. After long spells, horses should be stable-fed for a few days before beginning to work. Give them only a small amount for a start, and gradually get them used to feed. It is advisable to work them 2 or 3 hours on the first day, gradually increasing the length of time, until at the end of the week the teams should work full days without showing signs of distress. If horses are worked full time from the start they rapidly fall away in condition, besides getting badly scalded shoulders. Working horses are only capable of doing a given amount of work each day; if pushed beyond this point they lose condition, and one will not accomplish any more work—in fact, not as much, because the teams will be worn out, and not be able to travel so well. To get the maximum work from horses they should be carefully stabled, and have as much water as they will drink at least three times a day, and good, nourishing food—for preference, oaten hay chaff. Regular, punctual feeding is of paramount importance. Always feed enough, but not too much. Be sure that they always eat all the feed which is given to them. Horses should have free access to water; often times, when they first come in from work, they do not drink properly. Do not work horses after sundown, because the sweat is not likely to dry overnight, and therefore may cause a chill. To work horses half an hour after sundown is much more detrimental to their health than to work them several hours earlier in the morning. When driving horses do not ''push'' them. They will go their own pace, and will do much more work than ''pushed'' horses in the long run. Horses should be well groomed each morning before they are put to work. This not only adds to their appearance, but also assists in keeping them in good health. Horses should on no account be tied up overnight; if they are managed correctly they will all feed together at a long manger quite contentedly. The teams should be driven home from work, and not let run on their own accord, especially when there are brood mares among them. The teeth of horses should have careful attention. A large number of internal troubles are caused through bad teeth. Amateurs should not attempt the filing and cutting of the teeth. The hoofs should also be cut and trimmed whenever necessary. If they are left unattended for any length of time they split, and very often cause lameness. *Sore Shoulders.*—Prevention is always better than a cure; slight sores at times may be difficult, and perhaps impossible to avoid, but if a team of horses are well cared for one will seldom find sore shoulders. Collars should fit well, and be kept well lined and stuffed; sweat marks and dirt should be cleaned off the collars, and the horses' shoulders each morning before commencing work. The chains should be equal in length, and free from wire links. Mares in foal should be worked on the outside of the team, where they are not so likely to be bumped, and thus cause the loss of either the mare or foal. Mares in foal should not be turned out in paddocks to spell; they are likely to become over-fat, and when in this condition there is a danger of serious trouble at foaling. Mares that are used for breeding purposes should be kept out of any very heavy pulling; ordinary work will not hurt them, in fact, they should have light work until within a few days of foaling. When mares are about to foal they should be put in a separate paddock, away from the other horses, and, if possible, near the house, so that they can be watched and have attention, if necessary. Until foals are strong enough to look after themselves keep them with their mothers, away from the other horses. When weaning foals put them in a paddock where they can get plenty of exercise, water and feed, and out of sight of their mothers and other horses. If foals are properly handled from birth they require very little breaking in, and if the following method is adopted it will greatly minimise the risk of injury to both man and foal:—When the foal is only a few days old it should be caught and handled and stroked and have its legs lifted. A small halter should be put on the foal, and it should be tied up for a few minutes. This handling should be repeated every few days until the foal is thoroughly used to it; then it should be taught to lead. Foals should not be tied up with a rope around their necks; use a halter and a rope, and this will prevent choking down. If it is well grown a colt can commence light work at 2½ years, but only for about 2 hours a day for the first few days, gradually increasing the length of time until it is quite fit to work with the rest of the team. Commence working a young horse in fallowing time. At that period a few hours lost is not so important as at harvest or seeding.''

At the April meeting of the Morchard Branch a paper written by Mr. B. Koch advised breeding horses which were not too heavy in the legs. Heavy-legged horses carried a quantity of long hair around the fetlocks and if worked on wet or muddy land were liable to collect mud on their feet, becoming very slow and tired before the day was finished. An endeavour should be made to obtain a team even both in size and pace. A foal or two should be bred each year to keep up the strength of the team. Horses should be watered before being fed, otherwise they would contract indigestion or colic. They should be watered at least three times a day in summer. The trough should not be too close to the stable. If it were, the horse would carry a good deal of chaff and hay to the water. A team on heavy work would keep up its strength better if stable fed. Hay chaff should be fed morning, noon and evening, with plenty of crushed oats, and long hay at night. Grooming should be done every morning. If time could not be spared to groom the horse all over, the shoulders should be brushed to remove dried sweat, grooming being a great help in preventing sore shoulders. Collars should be a fairly tight fit, as a loose collar would soon cause a sore patch. With a team of more than seven horses tandem working was best, each horse being obliged to do his share of the work; the pull on the shoulders was less than with the shoulder swing. The stable should be open to the north; it would not be so cold at night, and the sun would shine in during the middle of the day.

The following paper was read by Mr. J. Kostera at a meeting of the Whitwarta Branch held on 16th March:—

The mainstay on most of the farms in South Australia is its team of horses. With a little care and careful management in the way they are fed, in the manner in which they are trained, and the attention to their health, they can be a team of good appearance and be admired by many a passer-by On a large proportion of farms, the horse is the most neglected animal; it does not get half the care and attention to which it is entitled.

Watering.—Horses should, if possible, be watered first and fed afterwards; this should be the general rule. However, it is not always convenient or possible to water before feeding, and very often the horse has a mind of its own and will not drink when one wants it to. In such a case if some little time elapses between feed and watering, the horse should not suffer any ill effects. The question also often arises whether a horse should drink when hot. It will not hurt him if he is used to it. Horses when grazing in the paddock should have access to water whenever they like, and attention should be paid to the watering troughs to see that they are kept clean and in good order.

Feeding.—This is a very important item of horse management, and the farmer must use his own discretion to a great extent. The mangers should not be filled and then left until empty before another refill. There are two wrongdoers in feeding horses—the man who under-feeds and the man who tips in too much at a time. I recommend feeding four times a day and giving each horse as much as it will eat and no more. The feed overnight should be heaviest, so that the horse will not be hungry in the morning and will require only a small feed for breakfast. Dinner should be the richest feed of the day, because the horse is usually given only a short time to eat. Oats rank as one of the best grains for horses, and have been found to be the finest feed for horses of speed and for those in very hard work. Horses will eat oats in preference to all other grain, and they may be fed whole or crushed.

The proper way to keep horses is to have a stable—a straw one will do if you cannot afford a better one. The managing of the horses in the stable is made much easier if every horse has its particular place or stall and is tied up, especially for the morning and mid-day feeds. The practice of tying up is by far the best, and has many advantages over other systems. Every horse learns to know its place, and will go to it at a word from its master. This system also has the advantage that every horse will get its share of feed and will not be bossed from one end of the stable to the other by one or two unruly horses. The harness can be hung on a peg at each horse's stall, which saves the necessity of running around the yard with a pair of winkers for a particular horse. Not only does this method save one's own energy and time when harnessing a team, but it teaches the horses to be quiet. Horses should be let loose at night so that they may go to water whenever they wish.

Grooming.—Each horse should be thoroughly brushed and groomed before going to work. Do not brush the shoulders alone, but go all over the animal, removing all sweat from the previous day's work. The little extra time involved is made worth while, it enhances the coat and helps to make the horse feel more comfortable, and also puts a better appearance on the animal. A straw stack near the stable may save a great deal of time when grooming, but do not let the straw stack do it all. A straw stack can also provide some shelter and warmth on a winter's night.

Harnessing and Sore Shoulders.—The collars should be close fitting, not too wide nor too long. Big collars are the cause of many sore shoulders. The hames should be fitted well up to the collar with the draft hook fairly high up from the point of the shoulders, for it is on the point of the shoulder that most sores occur. It is a common fault to see the points of the hames hanging down two, three, and even four inches from the collar. That is another source of sore shoulders. The hames should fit snugly around the collar and should be strapped tight. Tight hames also help to keep the collar together better. Sore shoulders are mostly caused by carelessness, lack of humanity, and bad management.

If a team is fed and handled on the lines suggested, with a good man in charge, the owner will have something to be proud of, and will not be far behind the tractor man at the end of five years.

RIVER MURRAY PRUNING COMPETITIONS.

At a Conference of River Murray Branches, held on 1st May, at Barmera, to consider rules and conditions of the forthcoming Competitions, the Secretary (Mr. J. J. Odgers) presented the following report on last year's competitions:—

The River Murray Pruning Competitions held during the past year were again successful, and at each district (Mypolonga, Barmera, Berri, Moorook, Cadell, and Waikerie) keen interest was shown, one pleasing feature being the number of junior competitors. In 1933 Mr. W. Langdon Parsons donated a fine silver cup for competition between districts, the ultimate winner being the most consistent pruner over a period of 3 years. This aroused interest, and each year the contest has been keen. The winner in 1933 was E. A. Liddicoat, Moorook, 548 points; 1934, H. M. Perkins, Berri, 539 points; 1935, C. Curtis, Waikerie, 549 points; whilst the most consistent over the period was C. Curtis, of Waikerie, with 1,618 points, closely followed by H. M. Perkins, Berri, with 1,615; A. Wedd, Mypolonga, 1,613; E. A. Liddicoat, Moorook, and W. E. Rout, Berri, 1612.

The Championship was held at Moorook, 15 competitors taking part, and the pruning was, as it should be, very good, only 3 points separating the 5 top competitors in the aggregate. The results were:—

Vines.—1st, H. M. Perkins, Berri, 283 points; 2nd, E. A. Liddicoat, Moorook, 282 points; 3rd, S. Loxton, Moorook, 281 points.

Trees.—1st, A. Wedd, Mypolonga, 266 points; 2nd (equal), G. Elliott, Waikerie, and W. H. Harris, Berri, 260 points.

The aggregate trophy, valued at 3 guineas, was presented by the Dried Fruits Board, and the winner was W. H. Harris, Berri, with 538 points. The other trophies were 2 cups, donated by the Royal A. and H. Society, for vines and trees respectively, and valuable manure trophies from Wallaroo-Mount Lyell Fertiliser Co. and Adelaide Chemical & Fertiliser Co. The donors of these various trophies have been staunch supporters of the competitions, and the committee appreciate their valuable assistance, which has added to the interest of the competitions.

A well-attended meeting was held in the evening at Moorook. Mr. J. B. Murdoch, member of the Advisory Board, addressed the meeting. The Secretary stated that Mypolonga had asked for a championship to be held there, and he asked pruners to discuss, and make a recommendation. This was done, and, after a good discussion, the pruners unanimously recommended the next championship to be held at Mypolonga.

MILLING QUALITY OF WHEATS.

At the April meeting of the Booleroo Centre Branch Mr. R. W. Reichstein reported on the results of tests conducted by him, and carried out by the Laura Milling Co., to ascertain the milling quality and gluten content of 8 varieties of wheat grown in the Booleroo Centre district. The wheat samples were tested by the "Pelshenke" wholemeal fermentation method, and the results were as follows:—

No.	Variety.	Soil.	Super.	Time of Sowing.	Test No. Mins.	Remarks.
1	Ranee ...	Red Clay	90lbs. Guano 33%	Mid June	35	About average.
2	Ranee ...	Dark Loam ...	60lbs. 45%	Early May	45	Fairly Good
3	Teakle ..	Red Clay	90lbs. Guano 33%	Late May	61	Very good (worth 1d. above F.A.Q. price).
4	Teakle ..	Dark Limestone	90lbs. 45%	Late May	44	Fair.
5	Nabawa .	(Rain 5·40in.)..	—	—	44	Good for Nabawa.
6	Ghurka .	(Rain 5in.)	91lbs. 45%	Mid June	29	No good.
7	Gallipoli .	Red Hard soil .	91lbs. 45%	Early July	33	The best we have tested for Gallipoli. (Usually under 25 minutes.)
8	Ranee 4H	Black loam (Rain 4·40in.)	120lbs. 45%	—	53	Good, should be worth 1d. over F.A.Q.

Mr. Reichstein stated that the test was made with the intention of finding out if there was any difference in the same wheat grown on different soils. Each sample had varied. No. 1, grown on red clay soil, was not as good as No. 2, the same wheat grown on a dark loam. With Teakle the position was reversed, that grown on a red clay giving a better test than that from a dark limestone soil. Ghurka showed a poor test, while Gallipoli gave a better test than was usual from samples of that variety. The 53min. test from Ranee 4H was very good for that variety. The dryness of the season might have contributed to the enhanced milling quality and gluten content of the wheats.

HARVEST REPORTS.

Members present at a meeting of the Frayville Branch on 5th March gave reports of their harvest results as follows:—W. Lindner: Ranee 8 bags, Sword 7, Nabawa 7½, stubble 10bush. H. Rosenzweig: Nabawa 8 bags, Sword 5, Ranee 5, ploughed ground 3 bags. W. R. Pese: Ranee and Sword 8 bags, Ghurka 6 bags (finished very badly), ploughed land, oats 5 bags, barley 4 bags. H. B. Scheer: Sword 19bush., Nabawa 11bush., oats 6½ bags. E. Hoffman: Gluyas 8 bags, Currawa 6, Sword 5, Nabawa 5, late sown Sword 3½ bags. O. Rosenzweig: Oats 15-16 bags; where super was sown 6 weeks before usual seeding time no apparent difference resulted. H. Krause: Sword and Ranee 7 bags, Ranee 4H 4½ bags (badly rust infected), oats 7 bags (badly shaken). G. A. Quast: Best return from Nabawa, 6 bags. S. A. Bretag: Ranee 4H 27-28bush., Ghurka 22 bush. (infected with rust), Sword 22bush., Nabawa 17bush.

WARRAMBOO.—A meeting was held on 3rd April, when 8 members gave reports of their harvest results. Members agreed that stubble ground gave best results where sown early and dry. Cape barley seemed to be more suitable for feed than malt. One member had sown both in the same paddock. The stock lived on the Cape barley, leaving the malt alone. Two members reported best results from grass land cultivated early and worked after the rains. Members agreed that fallow should be ploughed early and worked as little as possible until the autumn in order to avoid drift, keeping the land as clean as possible by the use of sheep. Ranee wheat gave promise of yielding well in the Warramboo district.

QUESTION BOX.

A "Question Box" was the subject of the meeting of the Wallala Branch on 14th March, nine members being present. Among the questions dealt with were the following:—*Question:* Is it safe to use a poison cart for poisoning rabbits where sheep are being grazed? *Reply:* Yes, provided care is taken to see that the baits are properly covered. The use of a drill harrow would assist in covering the baits. *Question:* Best method of dealing with rabbits? *Reply:* The poison cart followed with cyanide Sulphur and saltpetre were also recommended. *Question:* Best oil to use in farm machinery? *Reply:* Vegetable oils were best, but owing to their high cost, mineral oils of the best grade were recommended.

Millicent.—At a meeting of the Branch held on 27th March the following questions were dealt with:—

"Top Dressing Twice Yearly."—Mr. Skeer asked if any member had had experience with top dressing twice a year. He had heard that two applications were given in parts of Victoria. Messrs. Reschke and Soper, of the Coonawarra Branch, gave some interesting information. Mr. Reschke said he had tried it with success on a 20-acre paddock. The first application was a cwt. of superphosphate, and the second application was 80lbs. Mr. Soper said that in Victoria it was the usual custom to top dress twice annually. For the first three years a cwt. of super to the acre was used, but after that 1cwt. to the acre in two dressings of equal quantity. He found that in some seasons feed grew prolifically and to a great height, and he would not advise the double dressing unless it was proposed to cut the grass for clover hay. One objection to the denser growth was the encouragement of footrot. Mr. R. A. Hately said he did not think double dressings were advisable in areas where the rainfall was under 20in.

"Footrot."—The statement that increased growth would encourage footrot caused quite an interesting discussion. Mr. Skeer said he had read quite a lot about the subject recently. One authority claimed that the germ was in the soil, but if sheep were not in the paddock, it would not stay in the ground more than 30 days. Another authority claimed that infestation was caused by carriers, and if these were not treated, trouble would necessarily follow.

Mr. R. A. Hately quoted his experience of 12 months ago, when he purchased two flocks of sheep on the same day. They were put together in one paddock. One of the mobs developed footrot, but in the other there was no sign of the disease.

Mr. L. L. Hately said he had known a case where affected sheep were running in the same paddock as other sheep which did not become affected.

Mr. Reschke said footrot was easily overcome with foot baths. He said he had an instance where 30 lambing ewes in a flock of 1,000 sheep were affected. They were treated with formalin and spirits of salts, and the following year there was no sign of trouble. He was satisfied there were two distinct types of footrot; one was a germ in the blood, and the other was in the soil.

Mr. Skeer said he had treated affected sheep with formalin, and one application had been sufficient.

Mr. H. J. Hutchesson said he had constructed footbaths and had used bluestone with success. He had not been greatly troubled with the disease.

Mr. Reschke advocated making footbaths 25ft. long, 10ft. wide, and 6in. deep. He said sheep should be left in the bath for about two hours. If sheepowners all had footbaths there would be little trouble with footrot.

Pygery.—At a meeting on 7th April, when eight members were present, Mr. Edmonds asked why various brands of super ran through the drill at different rates? *Reply:* New super appeared to be moist and ran slowly, while old, dry super ran more quickly. *Question:* Best quantity of super to sow per acre? *Reply:* Members preferred to sow at the rate of 1bush. per acre. *Question:* Has any member tried shares on harrows? *Reply:* They were effective if used when weeds were young. With four leaves of harrows an extra horse would be required.

CARE OF THE FARM ENGINE.

In the course of a paper read at a meeting of the Boor's Plains Branch on 2nd April; Mr. A. Adams stated that overloading was an enemy to any engine and was unfortunately too often in evidence. Overloading was particularly hard on a tractor or stationary engine, which had to perform its task hour after hour without any respite. Cooling was important. An engine could not give best results if it was overheating. Overheating could be caused by such factors as dirty tanks or radiator, slipping fan belt, weak or late ignition, worn piston rings allowing gases to escape between piston and cylinder walls, faulty lubrication, or excessively weak fuel mixture. If the above items were in order and the engine was not overloaded the minimum of trouble should be experienced. Ignition of most farm engines was by the magneto system. The magneto should be kept clean, with the contact breaker points working freely and adjusted correctly to a gap about 1/32in. Emery should never be used for cleaning the distributor, because it roughened the surface, thus causing rapid wear of the carbon brushes and consequent misfiring; a drop of petrol or kerosene on a clean rag was the best method. Filing of the contact breaker points should be done sparingly, more points being filed away than were burnt out. For grinding valves a fine valve grinding paste was best. After grinding, the head of the valve should be dipped in kerosene, the seat thoroughly cleaned to remove all grinding paste, and the valve rotated in its seat in the same manner as when grinding. The result would be a glassy finish on the valve and seat. Valve seat cutters should be used very sparingly and all valves kept in their respective places. Slightly more tappet clearance on the exhaust valves than on the inlet would help to avoid burnt exhaust valves. Before fitting new rings, all carbon should be scraped from the grooves in order that the rings should not bind. The rings should then be fitted to the cylinder leaving a small gap for heat expansion. To avoid rings dropping into the wrong groove the rings could be slipped on over three thin strips of tin. In the case of oil engines it was important that the blow lamp should work correctly. The engine should be well heated before attempting to start it, although overheating should be avoided, because it tended to cause the engine to smoke and back-fire, as well as damaging the heat coil. Petrol-kero. engines should be well warmed before switching on to kerosene. An insufficiently warmed engine could not burn unvaporised fuel, which would find its way past the pistons, destroying the lubrication of the cylinders and diluting the oil in the sump. It was important to be sure that the engine had an ample supply of good lubricating oil. Where an engine was running well it was not advisable to tamper with it in order to correct some fancied trouble. Cleaning of the outside surface was not as important as regular attention to the working parts.

BEE KEEPING.

Paper read by Mr. W. G. Ahrens at a meeting of the Greenock Branch on 16th March, 1936:—For most successful beekeeping, I consider the following five points to be the most important:

1. A good locality.
2. Mobility.
3. Standard hives.
4. A good strain of bees.
5. Young queens.

1. *Locality.*—By a good locality, I mean one where there is sufficient honey-yielding flora within a radius of two miles of the apiary for the bees to work on. The red gum constitutes the chief source of supply in South Australia. The quality of red gum honey is second to none, excepting perhaps, lucerne honey. The drawback of the red gum is that it flowers only every other year, and large beekeepers are therefore compelled to move their bees to other parts during the off season.

2. *Mobility.*—It is very important that a man who relies on beekeeping for a living, should be in a position to take advantage of every honey flow that may take place, within reasonable distance, and for this purpose a motor lorry is very necessary.

3. *Standard Hives.*—Most of you have had the experience of stacking fruit trays of uneven sizes, and you are well aware that apart from the inconvenience and waste of time, the moral influence is very bad. The same applies to hives only more so. Hives and frames, must be absolutely standard if the owner wants to avoid an early grave.

4. *Strain of Bees.*—The two most popular strains of bees in Australia, are Golden Italians and leather-coloured Italians, although the Carnolian black bee appears to be gaining favour in some localities. Of the first two, I prefer the leather-coloured Italians. The Goldens are often better honey gatherers, but do not stand the winter so well, and sometimes come through very weak, or die altogether. Black bees work very well at times, but are inclined to swarm too much. The chief aim of a beekeeper should be the production of honey. The amateur beekeeper is inclined to lose sight of this important point, and concentrates on the multiplication of colonies, with the result that by the end of the season, he has a lot of bees, but not much honey, because bees that are rearing excessive brood cannot store a great deal of honey.

5. *Queen Bee.*—No beekeeper can hope to be successful unless he is prepared to devote a fair amount of time to requeening. That means replacing the old queen by a young one, not when the old one is worn out, but as soon as she is past her prime. To emphasise the importance of this point I quote a few figures. (1) A strong colony contains anything from 30,000 to 50,000 bees; (2) the average life of the worker bees, during the busy season, is about 6 weeks. The wastage of bees during the long summer day is tremendous, and this wastage must be replaced to keep the swarm up to strength, and for these reinforcements we rely wholly and solely on the queen. Now everyone knows that to keep a Leghorn hen laying at the rate of one egg per day she must be young, and in good condition. The same applies to a queen bee if she is to lay 1,000 eggs per day, which she should be quite capable of doing. To accomplish this, it is also necessary that she should be fed on highly concentrated food. The workers attend to this. In fact the queen is quite incapable of feeding herself. If shut in a cage with an abundance of food she will be dead within a few hours. In view of the fact that in this district we have a honey flow only every other year, and that it lasts only about six weeks when it does come, it will be readily seen how disastrous it would be should one's queens become feeble or die just at the commencement of the honey flow. The last of her progeny would emerge from the cells within 21 days and then the swarm would dwindle very rapidly. The swarm is composed of three kinds of bees—drones, workers and the queens. Most people seem to be under the impression that drones are absolutely useless, but that is not the case. They certainly do not work, but are very necessary all the same. The beekeeper will obtain no young bees unless he has drones in his apiary; they are the male bees.

Workers.—Gale (page 64) states:—"Working bees are the rank and file of the hive: the architects, the builders, the preparers of building materials, the purveyors, the cooks, the nurses, the inspectors of nuisances. and scavengers, the sentinels, and the defenders. All and every bee, when at home, has to fulfil these and many other other duties, at some time during her indoor life, from the day she escapes from the chrysalis, till she goes out to procure home supplies."

Queen Bee.—The queen lays two kinds of eggs, male and female, and she can determine the sex of the egg as she lays it. These eggs if not interfered with, will hatch two kinds of bees, drones (males) and workers (females). Now the question arises, "Where do the young queens come from?" They are simply manufactured by worker bees, from worker eggs. It is possible for the bees to produce a perfect queen from any worker egg. The eggs selected for queen production are supplied with a special food commonly called royal jelly, which completely alters their development. The effects produced by this special food are:—(1) The young queen reaches maturity in 16 days instead of 21 (that being the period required for the development of a young worker bee) although being more fully developed it should, according to ordinary analogy, require longer; (2) its organs of reproduction are completely developed, so that it can fulfil the office of a mother; (3) its size, shape, and colour are greatly altered, its lower jaws are shorter, its head rounder, an its abdomen without the receptacles for secreting wax, its hind legs have neither brushes nor baskets. The first thing the young queen does, when she emerges from the cell, is to search the hive for other queen cells and destroy them should she find any. On the sixth or seventh day after emerging from the cell, she will leave the hive in search of a mate. This is the only time a queen leaves the hive, excepting when she issues forth with a swarm, and as beekeepers don't encourage swarming, the majority of queens leave the hive but once during their lifetime. The mating takes place in mid-air, and the queen then returns to the hive. She is now fertile for life, one mating being sufficient. The drone also mates but once, as he dies the same day. About four days after mating the young queen will start laying, and will continue to do so until displaced by another queen. Remember that in beekeeping over 50 per cent. of the diseases originate in the "side-liner's" apiary, therefore, for the sake of those who rely solely on beekeeping for a living, look after your two or three swarms, and keep them free from disease. Never try to nurse a weak swarm through the winter, unite it with a stronger one. See that your bees have ample stores before the cold weather sets in, then leave them severely alone until the following spring. Do not expect the bees to get to know you; they are here but a little while, you are here a comparatively long time, therefore it is your place to get to know the bees and treat them accordingly. Do not get excited if you happen to get more than your usual quota of stings. Excitement is contagious, and when bees get excited their temper is not improved. If you must retire, do so with as much grace as possible; an orderly retreat is never so humiliating as an absolute rout.

SEEDING PREPARATIONS.

The following paper was read by Mr. W. A. Mills at the April meeting of the Booleroo Centre Branch:—

At this time of the year quite a lot of preparatory work can be done in readiness for seeding.

Seed wheat can be graded and pickled, and if horses are being used a good quantity of hay can be chaffed. Swings and chains can be overhauled, harrows prepared, and other implements seen to.

As far as working the land is concerned, one cannot do much when the land is dry, but if rain falls it is quite a good idea to go over the fallows with the harrows, thus helping the weeds to germinate and at the same time conserving the moisture, leaving the land in good order for the combine and helping to form a good solid seed bed.

No definite time to start seeding can be set down; this entirely rests with the condition of the fallow and the weather conditions. If one waits for the rains, the land works better, one can deal with the weeds, the grain germinates better, and the crop stands the hot winds better in the spring on land seeded damp. The month of May is preferable for seeding if conditions are favourable but the last two seasons have shown that no definite tim can be laid dow.n

The quantity of seed and super to use per acre rests with the individual farmer. In sowing Ranee 50lbs. of seed per acre for this district is quite sufficient. Ranee stools out well, and if sown very thick the heads are inclined to be small as well as the grain. If an early variety is sown for hay more seed per acre is needed to ensure a thick crop.

The quantity of super depends entirely on the nature of the soil. Red stiff land needs more super, but on mallee and limestone ground 60lbs. per acre is quite a fair dressing.

The above was the subject of a paper read at a meeting of the Redhill Branch by Mr. I. L. Jones who stated that the recognised basis for sucessful wheat farming was fallowed land. The benefits of fallow were (1) Conservation of moisture (2) Accumulation of nitrogen (3) Control of weeds (4) Larger area of land in good condition for seeding. For years it was thought that the main aim in fallowing was to conserve moisture. It was now found that the fallowing promoted nitrates in the soil essential to the growing plant. The accumulation of nitrogen in the soil occurred most in Spring when the temperatures were rising and in Autum when temperatures were falling. It was obvious that early fallow would have a big advantage. Spring workings of early fallow would result in increased aeration of the soil, which played a big part in the accumulation of nitrogen. Lack of nitrogen in crops was evidenced by the yellowing of the flag, poor stooling, and spindly plants. With a good fallow was associated a good, firm seedbed, in which plants would thrive better than if sown in loose, cloddy soil. The surface soil covering the seedbed should be free from clods, which held no moisture. Sheep played an important part in forming a good surface mulch by tamping the ground and breaking up soft clods. Fallow should not be ploughed too deeply. Deep working required more attention and was liable to promote take-all. Stubble should not be ploughed in, as it keep the soil too open. Good fallow shoud be sown with good, selected and graded seed. Dry pickling was more satisfactory as well as more convenient than the bluestone method.

In the course of a paper read at the April meeting of the Monarto South Branch Mr. H. Patterson said that recent summer rains had made quite a lot of fallow working necessary. Where a springtooth was used it was very necessary to use it often and at the correct time, especially where dandelion was troublesome. The use of shares which were no longer efficient was a bad practice, especially just before seeding. All heavy land should be fallowed where possible. The best treatment for light soils was to plough or cultivate early, and after leaving the land for the time, harrow it and sow with barley and oats by means of a combine. Seed should be graded or recleaned and pickled, dry pickle being recommended. One bag of super per 2 acres was a suitable dressing for average soils, and with the reduced price it was better to use a little more rather than a little less. The time of sowing suggested was from the last week in April to the second week in June.

BARLEY GROWING.

[Paper by Mr. G. G. Pearson read at a meeting held at Yeelanna, 1st April, 1936.]

Soil and Climatic Conditions play so important a part in barley production as to make a few remarks under this heading essential. So far as the bulk of the area sown in South Australia, other than the extreme south-east is concerned, most is in the good rainfall districts with a subsoil of good clay not too deeply removed from the surface. Areas where broom and mallee thrive together in their natural state can be relied on to produce a reliable sample of barley almost every year. Much harm has been done to the industry by attempting to grow barley in unsuitable areas and producing poor samples which depress the market both by reason of their quantity and quality and thereby prevent the grower in suitable areas from receiving adequate return for his better product. The district here should, in my opinion, be the equal of any place in South Australia as a barley-growing area.

Marketing Conditions also have a considerable bearing on the question, so much so that the area sown, type, and rotation have to be considered in relation to them. Quality should be the first consideration, for only a good type is readily saleable and a lighter crop saleable as first grade barley should be aimed at in preference to a heavy crop which has far less chance of good maturity. I would strongly stress this point in the interests of the industry generally, and think it will be found that only unusually good finishing conditions will mature a heavy crop.

Types.—The Chevalier and Pryor types are most popular as a two-row type and are generally known as English barley. They suit local maltsters, are a good stubble crop following wheat, mature early so as to be out of the way before wheat is ripe, and provide very palatable dry feed for stock when grass paddocks are nearly done. In addition, the straw is easily converted into a mulch and provides an easy way of getting good humus into the soil if ploughed under at fallowing time, which on older land is to be preferred to burning. The six-row type has many disadvantages, and although it often yields more heavily and does not lodge or break off much, has a much smaller market, particularly if not of the best quality. It has a coarse, fibrous straw not nearly so much relished by sheep and, so experts warn us, makes a very much greater demand on the components of the soil needed by the wheat crop. This is proved by the experience of a neighbour of mine who grew five crops of English barley in successive years on the same piece of land. His last crop returned nearly 20bush. per acre, after which he fallowed the land and grew 30bush. of wheat without any sign of weakness whatsoever. In contrast to this we are warned by experts to be wary of the effect of even one crop of the Californian type on the ensuing crop of wheat.

Stubble-Grass or Fallow—Barley on fallow is rarely practised and is to be discouraged for reasons of the quality of the grain. The plant invariably makes prodigious straw growth and matures a poor grain, though, of course, a heavy yield, but not sufficiently heavy to compensate for the cost of fallowing. Some farmers on Yorke Peninsula have stated that they intend to discontinue sowing barley on stubble land after wheat on account of unsatisfactory returns and intend to use ley land entirely for this crop. This is wrong, for several reasons. The state of the market is probably the strongest reason, as has been cited earlier. An analysis of my experience seems to suggest that the stubble crop is almost as payable as the grass. Soil preparation is cheaper, super dressings lighter, a better rotation is possible, and the quality is almost assured. I have never grown a second grade sample on stubble land, and have reaped 15 bags per acre. With the correct method of soil preparation stubble land will produce a satisfactory crop, and if practised more generally would pay the grower better in the long run.

Soil Preparation—Grass Land.—If a heavy body of dry feed covers the land, burn off the grass where it will run. Generally speaking, grass that will not carry a running fire is no deterrent, either to the working or to the crop. If time permits plough the land with the opening rains and give it a harrowing, but no advantage is gained by ploughing too early. I have frequently left the breaking up to be done during wet spells at seeding time and found it quite successful. Ploughing too early will probably mean an extra working to kill weeds which is not otherwise needed. Do not work dry nor too fine. What is good wheat preparation is not necessarily good for barley. Later ploughing kills a good crop of weeds and probably the bulk of the dandelion; then when wheat is sown or early in June a working with the combine will get another crop of weeds. The crop may be sown almost immediately afterwards. It may seem possible to do the sowing together with the cultivation and thus save a working, but I would strongly discourage this. The extra run over will pay in a cleaner crop and better yields. If conditions are so dry as to kill all weeds in one operation then be assured that it is too dry to be working barley ground at all. A suggested dressing is 60lbs. seed and 100-112lbs. high grade super. Barley may be sown very wet, if not planted too deeply, and good results will follow.

Stubble Land.—Burn stubble as late as may assure a clean burn, and on as calm a day as possible. Burn on small areas if convenient and harrow each piece at once. The cooler the day and the calmer it is the greater bulk of valuable ash will be conserved. The land may now be left until it is convenient to work it, the green growth being kept in check with sheep. Do not be tempted to work up dry, although it may work up well and cheaply. It may be all right if wet conditions follow, but in dry years it is fatal to good results. Work up well when convenient with a share-plough or heavy bridle-cultivator. If very rough give a harrowing before or after sowing with about 60lbs. seed and half a bag of super about the middle of June but not before. If early ploughed it may be necessary to work again, but unless the land is dirty no advantage is gained. However, do not work dry.

Subsequent Treatment.—There are some who advise and practice harrowing the crop when stooling, say about the third week in August. Although not always necessary, it is beneficial to crops sown earlier, and in dry years when wet workings are not always possible. The need is indicated by a period when growth seems to stop and the crop seems inclined to thin out instead of stooling. The colour lightens and the plant assumes a stale, frost-bitten appearance. Harrow heavily at this stage. If the ground is not too loose and the plants well established, a few plants pulled out will not matter. If crop has been sown and worked wet, and not too early, and has a deep green bunchy appearance and is stooling well, harrowing is not warranted. The crop may now safely be left to the climatic conditions to mature.

Summary.—Sow clean seed pickled wet with formalin. Use the plough or heavy cultivator for first working up. Work as wet as you can and not too finely. Give grass land the extra cultivation, and use harrows on the crop if necessary. Do not sow too deeply nor too heavily.

This BETTER tractor fuel is BRITISH

As Britain is Australia's best customer it is fair enough to suggest that Australian primary producers should use a British-Australian tractor fuel. And by using "C.O.R" Power Kerosene you'll work more acres per gallon and gain smoother, trouble-free running.

Available in convenient 24-gallon drums.

WOMEN'S BRANCHES.

SUBJECTS FOR BUREAU MEETINGS.

If you have no other subject in mind, here is a list from which you might choose when asked to contribute to your branch programme.

The Farm.

- Dairying—
  - Care of Milk and Cream
  - Buttermaking
  - Cheesemaking
- Pigs—
  - Bacon Curing
- Beekeeping—
  - Honey
- Horticulture—
  - Vegetable Growing
  - Flower Growing
- Poultry—
  - Dressing
  - Incubation
  - Rearing Chicks
  - Turkeys
  - Ducks

The Home.

- Home Management—
  - Furniture—
    - Choice
    - Repairing
  - Needlework
  - Knitting
  - Rugmaking
- Clothing—
  - Choice
  - Repairing
- Dressmaking
- Pattern Afternoon
- Children—
  - Care and Management
- Cooking—
  - Recipes
  - Recipes for Christmas
- Lunches
- Jam Making
- Fruit Preserving
- Fruit Drying
- Fruit, Value of
- Pickles and Sauces
- Sweet Making
- Exhibition of Home Crafts
- Christmas Gifts
- Home Nursing

General.

- Inter-Branch Visits
- Competitive Exhibition
- Flower Show
- Practical Demonstrations
- Social
- Music in the Home
- Good Reading
- Hobbies
- Physical Culture
- Labor Saving Hints
- Spring Cleaning
- Entertainment in the Home.

BUREAU CONFERENCE AT KYBYBOLITE.

Mrs. E. C. H. Schinkel presided over the Women's Sessions of the Lower South-East Bureau Conference, which was held at Kybybolite on 8th April.

A demonstration of Rug Making was given by Mrs. Harrison, of Naracoorte, and Miss E. Campbell (Education Department) delivered an address, "Balanced Diets."

'FANCY WORK.'

[Miss Audrey Marks, Penola.]

During the past few years fancy work of various kinds has become a very popular form of relaxation for most womenfolk, and instead of being regarded as merely a pastime for idle hands, as it possibly was a generation or two ago, the art of embroidery work can now be looked upon as being something of a necessity in a household, and many an hour can be spent in the long winter evenings as a pleasant pastime, especially for those who live in the country, where there are not the attractions that there are in the cities.

For years "fancy work" stood at almost one thing, and the ideas for linen work were not so varied or fascinating as they have become of later years.

The most necessary item for needlework is neatness. Loose ends, big knots, and jump-over stitches are most unsightly and unnecessary.

Always have clean hands. White work is very easily soiled, and this often loses points for one's work when it is judged. A lemon cut in halves and rubbed well into the hands cleans them well after gardening or any rough work. A very fine needle, and one strand of the cotton gives the best results when doing fine work.

It is better not to handle the work more than necessary, as it soon loses its sheen. There are numerous kinds of stitches, the three types of stitches which are used most frequently, and especially by the beginner, being Lazy Daisy, Satin, and Stem stitch. These are very easy to learn, and very effective.

There are other stitches, more intricate, that may be used at later stages, such as Indian Filling, Eyelets, Bullions, Richlieu Embroidery, Hedebo, and Drawn Threadwork.

Indian Filling is mostly used when doing coloured work, and is very effective when the shades used are blended. It is a long and short Satin Stitch alternately, the length of stitches varying according to the work being done. When working this stitch on poplin, always have stitches running with the grain of the material, otherwise it will pucker.

Satin Stitch is another much-used stitch, which must be well padded to raise it and give it the desired effect. Padding braid can be obtained in various widths, and saves a great deal of time in padding stems or ribbon bows.

The *Bullion Stitch* is used for rosebud designs.

Hedebo has come into prominence just recently, and is a very dainty and effective stitch.

Richelieu Embroidery is a beautiful work when executed properly in a good design. Richelieu washes well, and will stand a great amount of hard usage. In this work always buttonhole bars first, then buttonhole outlines, catching bars firmly at the same time. Richelieu work should be thoroughly pressed before it is cut out. Adding buttonhole picots to the centre of each bar gives a very pretty effect. The blending of colours can create a very interesting study, and one which any person can accomplish as there are now so many pastel shades on the market from which to select.

By the introduction of coloured threads and embroidering in these lovely shades the present-day fancywork is extremely fascinating. When one views the lovely specimens of work exhibited at shows and exhibitions one realises how high a standard of excellence can be obtained by anyone who may take care and patience in their stitchery.

Edges are another point to be considered. While there are many crochet edges, needlepoint, and the old form of handicraft known as tatting have now become very popular.

Embroidery must never be washed before being entered for competition at shows; if it has gone a little yellow in the making it is better to leave it alone rather than try to clean it. Judges realise that in some instances this is unavoidable.

When pressing the work place it on several thicknesses of turkish towelling or blanket, and press it on the wrong side with a damp cloth placed on it.

Careful mounting of the work makes all the difference, and it is always better to do this on fresh blue paper or cardboard rather than on other shades. This, of course, applies to white work—the blue will counteract any yellowness in the work.

"BENEFITS ARISING OUT OF BUREAU MEETINGS."

[Mrs. E. GOLDING, Mundalla.]

There is an old saying that we learn by our mistakes, but it is rather an expensive method. It is far cheaper to learn from the mistakes—or the experience—of others.

In the Bureau there are many women who excel in various branches of what is regarded as "women's work," such as the making of butter, jam and preserves, the baking of bread, dressmaking, and the hundred and one other things incidental to housekeeping.

The Bureau confers on its members the right to obtain knowledge under very happy social conditions. The Bureau also provides lecturers from various Government Departments, who are able to advise on matters relative to our work.

To the more fortunate members there is a visit to Adelaide to attend the Conference of Country Branches—the Annual Congress. Here one comes in contact and makes freinds with women from all parts of the State. Lectures are given by experts in various subjects, and interesting visits of educational value are arranged.

The social side of the meeting must not be overlooked. It affords great pleasure to meet and make new friends. I appeal to all those who are not as yet members of the Bureau to join, especially the younger ladies, for to them the Bureau can provide a fine training in domestic science. Keep your Branch together by your regular attendance, and make it interesting at all times.

EXHIBITION OF WOMEN'S HANDICRAFT AT KARTE.

Truly the women of the Mallee areas of our State, and especially those who live in the more isolated districts, are wonderful people. On Wednesday, 14th April, the writer was privileged to be present at the Exhibition held at Karte under the auspices of the local Men's and Women's Branches of the Agricultural Bureau.

Karte is a very small township, nearly to the end of the Peebinga line, and its nearest town of any importance is Pinnaroo, 20 miles distant. The farmers of Karte have not had a very encouraging time during the past 5 or 6 years, and it would not be surprising, if after such a depressing period, they and their women folk had lost all interest in organisations of this description. Yet the concensus of opinion of all those who attended, including visitors from Pinnaroo, Parilla, Parilla Well, Murray Bridge, and Adelaide, was to the effect that the Exhibition was a tribute to the wonderful public spirit of these pioneer women.

The residents of Karte have an enviable reputation in that whatever they do they do well, and certainly this, their first attempt at a fixture of this description, was an unqualified success, and one of which many a larger country town might be justly proud.

Mrs. F. N. Atze, an indefatigable worker for Women's Bureaux, has only been resident at Karte for a little over 12 months, but she has welded the women of the district into an energetic and capable band of workers. To her much of the credit for the success of the Exhibition is due. She was very ably supported by Mr. and Mrs. M. E. Small.

One of the farmers said, "This is a red letter day for Karte. We have never had anything like it before, and having been so successful we can confidently anticipate an even better Exhibition next year." In all, 268 entries were received.

Mr. F. C. Richards (Asst. Secretary of the Agricultural Bureau) declared the Conference open, and the following awards were made:—

COOKERY (Judges—Mesdames Young, Mattiske, and Webster, of Pinnaroo): *Loaf of Bread*—1st, Mrs. Freeman; 2nd, Mrs. Freeman. *Yeast Buns*—Mrs. Bierworth, Mrs. H. Gould. *Scones*—Mrs. A. Mattchoss, Mrs. Freeman. *Coffee Cake*—Miss D. Trowbridge, Mrs. Mattchoss. *Ribbon Cake*—Miss G. Fiebig, Miss D. Trowbridge. *Sponge Sandwich*—Mrs. Bierworth, Miss A. Trowbridge. *Chocolate Sponge*—Miss G. Fiebig, Miss E. Atze. *Jam Tarts*—Mrs. H. Trowbridge, Mrs. Atze. *Cream Puffs*—Mrs. C. Gum, Miss A. Trowbridge. *Biscuits*—Miss D. Trowbridge, Mrs. Mattchoss. *Dark Cake*—Mrs. Atze, Miss E. Atze. *Sultana Cake*—Mrs. H. Trowbridge, Mrs. Bierworth. *Small Cakes*—Miss A. Trowbridge, Mrs. Mattchoss. *Pickles*—Mrs. Atze, Mrs.

Mattchoss. *Tomato Sauce*—Mrs. Atze, Mrs. Bierworth. *Chutney*—Mrs. Furness, Mrs. M. Small. *Jam*—Mrs. Atze, Miss E. Atze. *Marmalade*—Mrs. F. Small, Mrs. Mattchoss. *Butter*—Mrs. Button, Mrs. Bierworth. *Eggs*—Mrs. Atze, Miss G. Fiebig.

FRUIT AND VEGETABLES (Judge—Mr. A. F. Young, Pinnaroo): *Collection of Fruit*—Mrs. A. Mattchoss, Mrs. Freeman. *Collection of Vegetables*—Mrs. Atze, Miss Fiebig. *Cucumbers (Apple)*—Mrs. Atze, Mrs. Bierworth. *Cucumbers (Long)*—Mrs. Atze. *Tomatoes*—Mrs. Small, Mrs. Atze. *Rhubarb*—Mrs. Atze, Mrs. Flavel. *Carrots*—Miss Fiebig. *Piemelons* (two sections)—Mrs. Small, Mrs. Button; Mr. M. Small, Miss Fiebig. *Trombones*—Miss Fiebig, Mrs. Small. Marrows—Miss Fiebig, Mrs. Bierworth. *Pumpkins*—Mr. Small, Mrs. Small.

FARM PRODUCE (Judge—Mr. R. L. Griffiths, District Agricultural Instructor): *Wheat*—A. Mattchoss, E. Huckel. *Oats*—A. Mattchoss, A. Bierworth. *Wheaten Hay*—A. Small, H. Gould. *Oaten Hay*—Miss Fiebig, A. Bierworth. *Lucerne*—Mrs. Small, M. Small. *Wheaten Chaff*—H. Gould, A. Mattchoss. *Oaten Chaff*—G. Atze, C. Atze. *Rabbit Skins*—H. Gould, M. Small. *Something Useful Made From Something Useless*—G. Atze, M. Small.

FLOWERS (Judges—Mesdames Johnston, Davis, and Napper, of Parilla Well): *Dahlias*—Mrs. Atze, Mrs. Mattchoss. *Cosmos*—Mrs. Bierworth, Miss G. Fiebig. *Gaillardias*—Mrs. Atze, Miss Fiebig. *Asters*—Miss Fiebig, Mrs. Trowbridge. *Vase of Flowers*—Mrs. Atze, Miss A. Trowbridge. *Sunflowers*—Miss Atze, Mrs. Atze. *Carnations*—Miss P. Button, Mrs. C. Gum. *Roses*—Mrs. Atze, Miss E. Atze. *Zinnias*—Miss Fiebig, Mrs. Atze. *Flower Not Named*—Miss Atze, Miss Fiebig. *Posy*—Miss D. Trowbridge, Mrs. F. Small. *Pot Plant*—Mrs. Atze, Mrs. C. Gum. *Fern*—Mrs. Atze.

FANCY WORK (Judges—Mesdames Welden, Carne, and Miss Colwill, of Parilla): *Bag Apron*—Mrs. M. Small, Mrs. Atze. *Table Centre*—Mrs. M. Small, Miss Atze. *Vanity Set*—Mrs. M. Small, Miss A. Trowbridge. *Cushion*—Miss E. Atze, Mrs. M. Small.

The school children were granted a half holiday, and during the afternoon sports and games were organised for them.

During the evening Mr. Richards handed the prizes to the successful competitors, and a dance and supper concluded a most successful function.

BUREAU EXHIBITION AT PARILLA.

The Fifth Annual Exhibition of Women's Handicrafts, sponsored by the Parilla Women's Branch of the Agricultural Bureau, was held in the local institute on Thursday, 15th April.

This function provided still further evidence of the growing popularity of the Women's Agricultural Bureau in the country districts of the State, and is an example of the co-operation that exists between Branches along the Pinnaroo Line, representatives being present from Wilkawatt, Parilla Well, Pinnaroo, and Karte—35 miles distant.

This year eclipsed all previous records, when 250 entries were received, and to encourage the junior members of the Branch special sections in which they could compete were included.

	First.	Second.
Brown butter sponge	Mrs. G. Harding	Mrs. G. Belling
Cornflour sponge	Mrs. H. Harding	Mrs. Smitham
Sponge roll	Mis. F. Belling	Mrs. Smitham
Sultana cake	Mrs. Welden	Mrs. O'Loughlin
Coffee cake (cinnamon top)	Mrs. Wright	Mrs. R. C. Kerley
Ribbon cake	Mrs. G. Belling	Mrs. R. C. Kerley
Napoleon cake	Mrs. Pearce	Mrs. F. Belling
Six cream puffs (3 filled, 3 unfilled)	Mrs. R. C. Kerley	Miss Colwill
One walnut roll with fruit	Mrs. Welden	Mrs. R. C. Kerley
Biscuits—6 different mixtures (3 of each to be named)	Mrs. Foale	Miss Colwill
Six pieces cut from cake and iced ..	Miss Foale	Mrs. R. C. Kerley
Rich dark cake	Mrs. F. Kerley	Mrs. Smitham
Decorated cake	Miss Foale	Mrs. R. C. Kerley
Collection puff pastry	Mrs. Colwill	Mrs. Pearce
Six jam tarts	Mrs. Foale	Mrs. Pearce
Six sausage rolls	Mrs. Pearce	Mrs. R. C. Kerley
Six white scones	Mrs. R. C. Kerley	Mrs. F. Kerley
Six coffee rolls	Mrs. Wright	Mrs. Foale
One only 2lb. loaf white bread	Mrs. F. Kerley	Mrs. R. C. Kerley
Six bread rolls	Mrs. Pearce	Mrs. Welden
Collection goods made from wholemeal (not bread)	Mrs. Foale	Mrs. Colwill

BUREAU EXHIBITION AT PARILLA—*continued.*

	First.	Second.
Six jars jam	Miss Colwill	Mrs. R. C. Kerley
Four jars preserved fruit (2 cut, 2 whole)	Miss Colwill	Mrs. R. C. Kerley
One glass marmalade	Miss Colwill	Mrs. R. C. Kerley
Three jars chutney	Mrs. R. C. Kerley	Mrs. F. Kerley
Bottle tomato sauce	Mrs. F. Kerley	Mrs. Smitham
Jar mustard pickle (mixed)	Mrs. R. C. Kerley	Mrs. F. Kerley
Jar clear pickle (mixed)	Miss Colwill	Mrs. F. Kerley
Jar pickled onions	Mrs. F. Kerley	Miss Colwill
Three tomatoes	Mrs. R. C. Kerley	Mrs. Colwill
One pound butter	Miss Colwill	Mrs. R. C. Kerley
Two-pound bar soap	Mrs. R. C. Kerley	Mrs. Smitham
Knitted jumper in 4-ply wool	Mrs. R. C. Kerley	Mrs. O'Loughlin
Mrs. R. C. Kerley wins aggregate.		
Collection of dahlias	Mrs. Welden	Mrs. Foale
Dahlias—		
One variety (6 different colours)	Mrs. Welden	
Three varieties (1 of each)	Mrs. Foale	Mrs. Welden
One cut show	Mrs. R. C. Kerley	Mrs. Welden
One cut decorative	Mrs. Schumann	Mrs. Welden
One cut cactus	Mrs. Welden	Mrs. Foale
One cut (not already mentioned)	Mrs. Welden	Mrs. Schumann
Vase of carnations	Mrs. Schumann	Mrs. R. C. Kerley
One cut carnation	Mrs. Schumann	Mrs. Welden
Three cut carnations	Mrs. Schumann	Mrs. Welden
Vase of Gallardias	Mrs. R. C. Kerley	Mrs. Welden
Vase of flowers not already mentioned	Mrs. Schumann	Mrs. R. C. Kerley
Vase mixed flowers	Mrs. R. C. Kerley	Mrs. Welden
One cut bloom not already mentioned	Mrs. Schumann	Mrs. Welden

JUNIOR SECTION.

	First.	Second.
Six white scones	Miss Carman	Miss Foale
Six small cakes (iced) made from one mixture	Miss Foale	Miss Carman
Puff pastry (6 pieces)	Miss Foale	Miss Carman
Supper cloth worked in colours	Miss Carman	
Tray cloth or table centre (worked)	Miss Carman	Miss Foale
Knitted jumper in 3-ply	Miss Carman	

EXHIBITIONS.

WIRRULLA.

A competitive Exhibition was held on 6th February. There was an excellent staging of fancy work, rugs, cushions, cosies and cookery. Misses Dennison and Mrs. F. Burfield, of the Auburn Branch, adjudicated and Miss S. Macklin won the prize donated by Mrs. W. R. Jones for the competitor gaining the highest number of points.

CLARE.

The success which attended the first Exhibition conducted under the auspices of this Branch—held on 7th March—should give the committee every encouragement to give this fixture a place on each year's programme of meetings. Visitors were present from the Belalie and Georgetown Branches. The section devoted to a display of antiques contained many articles of historical interest. The classes for needlecrafts and cookery were well supported, the judges—Mesdames Baily, Orchard and Syms—giving unstinted praise to the high quality of the exhibits placed before them.

NARRIDY.

Women's Branches of the Agricultural Bureau have staged many excellent exhibitions displaying the handiwork of their members, but it is doubtful if the fixture held under the auspices of the Narridy Women's Branch on 7th May, has ever been equalled. This Branch—to celebrate the completion of its first year's work—decided to hold a competitive exhibition of Women's handicrafts, entries to which would be restricted to its members. Under the able direction of Mrs. Klingner (President), Miss Brenda Reynolds (Secretary) and an enthusiastic Committee, the Narridy Women have set a very high standard for other branches if they are rival to them. The wonderful total of over 500 entries was received, and the judges who had had experience at the big agricultural shows in the Mid-North said of the needlework and jams, pickles and preserves classes, that these sections eclipsed both for quality and quantity anything that they had been called upon previously to judge. Twenty-nine entries were received in the class for 1lb. of farm butter. This was judged by Mr. J. O. Hatter (District Dairy Instructor) who confessed to having an extremely difficult task in naming the winner. Mr. F. C. Richards (Assistant Secretary of the Agricultural Bureau) opened the exhibition. The judges made the following awards:—

NEEDLEWORK.—Judges, Mesdames F. C. Spottswood and R. E. Lines (Gladstone).

Suppercloth—First, Mrs. W. C. Eagle; second, Miss V. Roberts. *Four Needlework Articles*—Miss V. Roberts, Mrs. W. Eagle. *Worked Cushion*—Mrs Eagle (1 and 2). *Teacosy*—Mrs. Eagle, Mrs. S. Darley. *Embroidered D'Oylies*—Mrs. W. Eagle, Mrs. S. Darley. *Two Tatted Articles*—Mrs. M. O. Smart, Miss L. Roberts. *Crocheted D'Oylies*—Mrs. W. Eagle, Mrs. M. O. Smart. *Embroidered Underwear*—Mrs. W. Eagle, Miss L. Roberts. *Article of Cross-Stitch*—Mrs. W. Eagle (1 and 2). *Worked Apron*—Mrs. Eagle, Miss L. Roberts. *House Frock*—Miss B. Reynolds, Mrs. Frick. *Article made from Sugar Bag*—Miss L. Roberts (1 and 2). *Homemade Rug of Wool*—Miss L. Roberts, Mrs. Eagle. *Homemade Rug other than Wool*—Mrs. W. Eagle, Mrs. R. Darley. *Child's Frock*—Miss L. Roberts, Mrs. M. Smart. *Duchess Set*—Mrs. W. Eagle, Mrs. S. Darley. *Table Centre*—Mrs. S. Darley, Mrs. W. Eagle. *Article made from Material costing not more than* 1s.—Mrs. M. O. Smart, Mrs. W. Eagle. *Embroidered Handkerchiefs*—Mrs. W. Eagle (1 and 2). *Knitted Sox*—Mrs. A. Klinger (1 and 2). *Article of Knitting*—Mrs. M. Smart, Mrs. S. Darley. *Baby's Outfit*—Mrs. L. Nicholson. Trophy presented by Mrs. Button. *Novelty*—Mrs. M. Reynolds, Mrs. W. Eagle. *Unspecified*—Mrs. W. Eagle (1 and 2). *Aggregate Prize*—Mrs. W. Eagle.

NEEDLEWORK SECTION FOR COMPETITORS NOT WINNING A PRIZE.

Doorslip—Mrs. A. Klinger, Mrs. J. Liddle. *Duchess Set*—Mrs. L. Nicholson, Miss M. Liddle. *Table Centre*—Mrs. R. C. Darley, Mrs. P. Smart. *Worked Apron*—Miss B. Reynolds, Miss M. Sandow. *Tea Cosy*—Miss M. Sandow, Mrs. Frick. *Supper Cloth*—Mrs. R. Smart, Miss M. Sandow. *D'Oylies*—Miss M. Sandow. *Crochet Work*—Mrs. L. Nicholson, Miss B. Reynolds. *Knitting*—Mrs. L. Nicholson, Mrs. R. Smart. *Unspecified*—Miss O. Sandow, Mrs. K. Saltmarsh. *Aggregate Prize*—Mrs. Sandow, Mrs. Nicholson.

NEEDLEWORK FOR JUNIOR MEMBERS.

Petticoat—Miss E. Sandow, Miss K. Nicholson. *Worked Apron*—Miss J. Richards, Miss E. Sandow. *Knitting*—Miss J. Richards, Miss E. Sandow. *Table Centre*—Miss E. Sandow, Miss K. Nicholson. *Unspecified*—Miss K. Nicholson, Miss J. Richards.

JAMS, PRESERVES, &c.—Judges, Mesdames H. Osmon and H. Bennett.

Six Jams—Miss L. Roberts (1 and 2). *Four Jellies*—Miss L. Roberts (1 and 2). *Three Marmalade*—Miss L. Roberts (1 and 2). *Six Preserved Fruits*—Miss L. Roberts (1 and 2). *Three Pickles*—Miss L. Roberts (1 and 2). *Three Sauces*—Miss L. Roberts, Mrs. P. Smart. *Three Chutneys*—Miss L. Roberts (1 and 2). *Unspecified*—Mrs. A. E. Klingner, Mrs. M. Reynolds. *One Dozen Eggs*—Miss L. Roberts, Mrs. L. Nicholson. *One Pound Dairy Butter*—Miss M. Sandow, Miss F. Sandow. Trophies presented by Mesdames Reynolds, Eagle and Mr. H. Pavey.

COOKING.—Judges, Mesdames H. Osmon and H. Bennett (Gladstone).

Fruit Cake—Miss V. Roberts, Mrs. J. Liddle. *Decorated Cake*—Mrs. M. Reynolds, Mrs. M. O. Smart. *Sponge Sandwich*—Mrs. K. Saltmarsh, Mrs. M. O. Smart. *Chocolate Butter Sponge*—Mrs. K. Mannix, Mrs. M. O. Smart. *Sultana Cake*—Mrs. M. O. Smart, Mrs. L. Saltmarsh. *Ribbon Cake*—Mrs. A. E. Klingner, Mrs. P. Smart. *Cream Puffs*—Miss M. Darley, Mrs. K. Saltmarsh. *Jam Tarts*—Mrs. C. Cox, Mrs. A. E. Smart. *Lamingtons*—Mrs. L. R. Nicholson, Miss K. Mannix. *Queen Cakes*—Mrs. M. O. Smart, Miss M. Sandow. *Sausage Rolls*—Mrs. A. E. Smart, Mrs. K. Saltmarsh. *Yeast Buns*—Mrs. M. Reynolds, Mrs. B. Reynolds. *Scones*—Mrs. L. Smart, Sen., Miss M. Darley. *Coffee Rolls*—Mrs. P. Smart, Mrs. A. E. Smart. *Nut Roll*—Mrs. A. E. Klingner, Miss M. Price. *Currant Cake*—Mrs. A. E. Klingner, Mrs. M. O. Smart. *Coffee Cake*—Mrs. K. Saltmarsh, Mrs. J. Liddle. *Bread*—Mrs. M. Reynolds, Mrs. E. A. Darley. *Biscuits*—Mrs. M. O. Smart, Mrs. M. Reynolds. *Aggregate Winner*—Mrs. M. O. Smart. Trophies donated by Misses L. Roberts and Messrs. A. W. Dawes and H. Prest.

JUNIORS.

Egg Sponge—Miss E. Sandow, Miss G. Saltmarsh. *Scones*—Miss E. Sandow, Miss D. Smart.

FLOWERS.—Judge, K. R. Hocking, (Crystal Brook).

Antirrhinum—Mrs. A. Freeman, Miss M. Price. *Three Distinct*—Miss M. Price. *One Chrysanthemum*—Mrs. A. Freeman, Miss L. Roberts. *Three Single*—Miss L. Roberts (1 and 2). *Six Japanese*—Miss L. Roberts (1 and 2). *Collection*—Miss L. Roberts (1 and 2). *Cosmos, Single*—Miss A. Freeman. *Cosmos, Double*—Miss M. Price. *Carnation*—Mrs. A. Smart. *Three Show*—Mrs. A. Freeman. *Collection of Carnations*—Mrs. Frick. *Dahlia, Champion*—Mrs. A. Freeman. *Three Decorative*—Mrs. A. Freeman. *Marigolds*—Mrs. C. Cox, Mrs. A. Freeman. *Pelargoniums*—Mrs. A. Klingner, Miss M. Price. *One Rosebud*—Miss M. Price, Mrs. R. Smart. *Three Rosebuds*—Miss M. Price, Mrs. A. Smart. *Rose*—Miss M. Price. *Three Roses*—Miss M. Price, Mrs. A. E. Smart. *Zinnia*—Mrs. L. Nicholson, Miss M. Price. *Three Zinnias*—Mrs. L. Nicholson (1 and 2). *Six Zinnias*—Mrs. L. Nicholson. *Chrysanthemums*—Mrs. L. Nicholson, Miss L. Roberts. *Cosmos*—Mrs. A. Freeman. *Carnations*—Mrs. Frick, Mrs. A. Smart. *Dahlias*—Mrs. A. Smart. *Marigolds*—Mrs. A. Smart, Miss L. Roberts. *Salvia*—Miss M. Price, Mrs. A. Smart. *Verbena*—Miss M. Price. *Gladioli*—Mrs. A. Freeman. *Bowls of Flowers—Yellow*—Miss L. Roberts (1 and 2). *Red*—Miss L. Roberts (1 and 2). *White*—Miss L. Roberts, Mrs. A. Smart. *Blue*—Mrs. A. Smart. *Stocks*—Miss M. Price. *Geraniums*—Miss M. Price, Mrs. A. Klingner. *Roses*—Mrs. A. E. Smart. *Antirrhinum*—Mrs. Frick. *Dahlias*—Mrs. L. Nicholson (1 and 2). *Chrysanthemums*—Miss L. Roberts Mrs. A. Freeman. *Zinnias*—Mrs. L. Nicholson, Mrs. A. Smart. *Cut Flowers*—Mrs. A. Smart, Miss M. Price. *Unenumerated*—Mrs. A. Freeman, Mrs. A. Smart. Trophies presented by Mrs. L. Nicholson and Mr. Burns. *Aggregate Prize*—Miss L. Roberts.

HANDMADE GARMENT.

Unspecified—Miss K. Nicholson, Miss G. Saltmarsh. Trophy donated by Mrs. A. Smart. In the evening, Mr. Richards presented the trophies, and a most successful day was concluded by a Supper and Dance—the music for which was supplied by members from the Beetaloo Women's Branch of the Agricultural Bureau.

NEW BRANCH AT OWEN.

A new Women's Branch of the Agricultural Bureau was opened at Owen by Mr. F. C. Richards (Asst. Secretary of the Agricultural Bureau) on 28th April. The following officers were elected:—President—Mrs. W. J. Marshman; Vice-President—Mrs. H. Helps; Secretary—Miss M. Lake; Members of Committee—Mesdames J. Williams and H. Moeller. Meetings will be held in the Methodist Kindergarten Hall on the second Thursday of the month, at 3 p.m.

MORCHARD.

The committee of the Women's Branch of the Agricultural Bureau at Morchard, and especially the Secretary, Miss F. Brown, deserve very sincere congratulations for the success which attended their efforts in staging their first competition of cooking and women's handicrafts which took place in the local institute on 25th March. With 161 entries to record on the occasion of their first attempt at a function of this description, they have been given every encouragement to conduct a similar fixture next year. Mr. F. C. Richards (Assistant Secretary of the Agricultural Bureau), who opened the show, said he knew of no better method of stimulating interest in Bureau work than the holding of such competitions. They served as an excellent advertisement for the Bureau and aroused friendly rivalry amongst those who took part. The judges of the various sections were agreeably surprised at the quality of the work placed before them, and it is worthy of special mention that Mr. Birrell, manager of the Orroroo Butter Factory of the Farmers' Union, said that the class for home-made butter was of exceptional merit. Many of the butters were equal in texture and quality to what one would expect to see produced during the spring months of the year. Mrs. Symonds, of Jamestown, judged the pickles, jams and sauces. She confessed that the high standard of the exhibits was an eye opener to her and her task had been anything but an easy one. The pickles could, with confidence, be shown at any show. The scones were the outstanding class in the cookery classes judged by Mrs. Pyne of Jamestown. The d'oyleys and supper cloths were highly praised by Mrs. E. L. Orchard, who was the adjudicator for the needlework section. The thanks of the committee are extended to the following who generously donated trophies:—Wepowie Branch of the Agricultural Bureau, Mr. S. Brown, Orroroo Cash and Carry, H. P. Davill & Co., South Australian Farmers' Union, Laura Milling Company.

SPONGE AND LAYER CAKES.

Reading a paper "Hints for Cooking Sponge and Layer Cakes" at the March meeting of the Maltee Branch, Miss R. Talbot said before baking is commenced have everything required handy and tins, &c., lined and greased. Use fresh eggs; they seem much lighter when well beaten, and a successful sponge depends greatly on the lightness of the eggs and sugar when beaten. Add each egg separately to the sugar and beat a few moments before adding the next egg. Nearly all layer cakes require butter, which should, of course, be beaten to a cream with the sugar before the eggs are added (unless stated differently in the recipe being followed). If a warmed basin is used, the sugar and eggs will mix more quickly and more thoroughly, which is a very important item. Beat the eggs and sugar for 10 minutes to quarter of an hour, and by that time the mixture is usually light and fluffy.

The flour and rising should be gradually folded in and mixed well, but not beaten vigorously. Plain flour, cream of tartar, and carb. soda with a little salt, are more successful than self-raising flour, and when sifted twice the cake should be finer in texture. A heaped teaspoon of cream of tartar, half teaspoon carb. soda, and pinch of salt to every cup of flour are the quantities I always use with success.

The prepared mixture should be poured into the sandwich tins (previously prepared), which should have the sides high enough to allow the mixture to rise sufficiently. Grease the tins well with a little lard or unsalted butter and dust with flour, so that the cakes will turn out easily without sticking.

A fairly hot oven is required for sponges, but as layer cakes nearly all contain butter, a moderate heat should be used. When testing a sponge to see if cooked (after being in the oven as long as recipe states), press lightly with a finger, and if sufficiently cooked, the imprint will quickly rise again. This is much better than piercing a hole in the top of the cake. The paper concluded with a number of recipes. (Secretary, Mrs. J. Ferguson.)

JAMS AND PICKLES.

In the course of a short paper, read at the February meeting of the Myponga Branch, Mrs. W. Magor said when making pickles it is most important to use good vinegar. Vinegar boiled with spices, cooled and poured over onions, makes good, crisp pickles, which retain their colour. For mustard pickles, the ingredients must be brought to the boil in vinegar to soften and boiled until one can pierce with a carving fork

The success of jams depends on the fruit used. Over ripe fruit does not make good jam. Firm fruit is best for jams and preserving. Marmalade is more trouble to make, but is a better jam for the extra trouble. Poorman's orange is the usual fruit for marmalade. Of late years grape fruit has taken its place. The jam competition was won by Mrs. Bounds with Mrs. Deverson second. (Secretary, Mrs. M. Bounds.)

WOMEN AND PUBLIC AFFAIRS.

At the Devlin's Pound meeting, held on 25th February, the following paper was red by the President, Mrs. S. A. Smith:—History speaks with no uncertain voice of the power of woman to command the admiration and mould the character of the age in which she lives. She has swayed the policy of nations and changed the map of the world; she is the most powerful factor in the changing story of humanity.

It is not the King on the throne, or the President in the White House, or the statesman with his logic and eloquence, or the soldier with laurels of military glory who controls this world—it is the women.

As we follow history down the ages we find many women of Biblical times taking very active part in the public affairs of those days. Sometimes their activities were for evil, but more often they were for the good of their people.

There have been our own English Queens, particularly the famous Elizabeth, who was very much in public affairs since she was a woman who knew her power, and used it to the utmost. Queen Victoria's long reign was noted for reforms, in many of which women took an active part.

Many great reforms of the past have been effected by women. We remember Florence Nightingale as the woman who, in face of tremendous difficulties, went to the battlefields of the Crimean Peninsula, and, with a loyal band of helpers, set an example of devotion to suffering humanity. Elizabeth Fry, who died nearly a century ago, made prison reform the object of her life. At that time men, women, and children were imprisoned under the most awful conditions. Through Mrs. Fry's work and influence. prison life in England was completely revolutionized. Mrs. Fry, also Mrs. Pankhurst, spent her life and money in working to gain the vote for the women of England Harriet Beecher Stowe, by her writings, did much in the cause of the abolition of slavery in America.

To come to our own day, and our own country, we find many women holding public positions—more than ever before. There are women lawyers, doctors, justices, heads of various departments, and women frequently sit on the bench of law courts. There are many women's associations which are doing excellent work, especially in matters affecting women and children, and surely in such matters there is none so qualified to give an opinion as women.

In advocating the taking of a share of public life it is not suggested that it should be taken in the spirit of rivalry between the sexes, but so far as possible in conjunction, for in the cause of humanity man's cause is woman's. To-day there is public work as perhaps never before, and, in women's cause, union is strength. There are the wrongs of women and children to be righted, there is unemployment, poverty, and crime to be contended with. What do women want? Is it knowledge, civilisation, the good of mankind? We must look facts in the face—we must do our part, each in making the world over—the brave new world of reason. The pen is mightier than the sword. Speech, written or spoken, is the main method of reaching the public mind. Women to be masters of their fate must speak and contend for their rights and their point of view.

The average country woman has just as much sense, wisdom of real life, and more courage to face its bad weather, emergencies, and hardships as the average city woman. We must get out of the habit of being victims of modesty and silence. In matters that affect us we must get into the habit of talking back, if it is only through the daily paper, and compel the attention and fire the imagination of those in authority with a sense of what we need and what we deserve. Remember that country women, the women of the land, have held the world together in peace and war, and they go down to their graves unhonoured and unsung, because they lacked the endless use of their tongues in public life.

Do you feel that your district has any needs? Are you satisfied with local conditions as they are? Do you think you and your children are getting equal consideration with city women and children? Do you ever compare your children's school and school life with that of children in the city? Do you compare our roads with city roads? Do you sometimes think of the frequent cheap excursions from the city to the hills and to the beach? Do you also think of the health clinics and the many advantages city people have? Do you think of their cheaper living, and our freight and transport problems? If you feel any of these things, it is time you became a woman of public affairs. From the little matters of our own district we move on to matters of State interest—we keep working for greater things: Strong souls and high endeavour, the world needs them now.

We have local committees, school, hall, and Bureau—just one idea of yours may work untold good. You may not see the fruit of your work; someone else may reap the harvest of it—that is no reason the work should not be done. If you are animated by the right spirit you will do it for the joy of the work. The Governor-General often said, while our State Governor, "Service is the rent we pay for our room on earth." Often one may get discouraged and despondent with the seeming lack of results, but there never shall be one lost good. There is no standing still in life, if we are not going forward, we are going backward. Public life takes more moral courage than physical courage; but it will grow on you, and your enthusiasm will grow also. Do not be afraid of your enthusiasm—turn it to account. You will be laughed at some times, but you will also be watched with interest. In practically every country in the world women are active in public affairs, not for the sake of glory, but in the great cause of mankind, in the betterment of the world. (Secretary, Mrs. J. Loffler.)

HOME CRAFTS.

Mrs. H. Queale read the following paper at the March meeting of the Boor's Plains Branch, which was attended by 15 members and five visitors:—Most women have a hobby on which to spend their spare moments—be they many or few—and try to make their hobby useful and profitable as well as a pleasure. With the aid of a packet of dye and scraps of cretonne or other coloured cloth, many attractive articles can be made from hessian or sugar bags. One of the easiest ways to dye the bag or hessian is by immersing them in a solution of Condy's crystals. They must be washed and placed in the liquid whilst wet, and according to the strength of the solution so will their colour be light or dark. Many shades from a golden brown to nigger brown are obtainable this way, and it is well to remember that the article is always a lighter shade than when wet. Stir the bag round in the liquid until it has absorbed as much dye as possible and then hang out to dry, when it is ready for use.

Oven cloths and aprons for outside work can be made from the sugar bag. Relieved with a binding of gaily coloured cretonne they are quite attractive. Peg bags made of the same material and with an ordinary coat hanger inserted in the top are very useful. These can be hung upon the line and pushed along as required. For those who like to rest their feet when sitting, reading, or serving, a stool can be made with seven tins—all the same size—and covered with the dyed bag. The tins are placed together in a six-sided figure and tied securely. Any old scraps of material can be pushed down between them and thus prevent any movement. Two cardboard circles the same size as the tins are then cut and one placed under and one on top of the tins. Two circles of material are then cut, allowing turnings, and one long strip for the outside of the tins. One circle and the strip can be sown together, and the tins placed inside, and then the other circle is sewn over the top. A padding can be made for the top with sheep's wool washed and teased. This is very soft and "springy." The seams can be covered with a cord or piping of coloured material. If the latter is used it should be sewn on at the same time as the circles. The wool also makes excellent filling for cushion covers, which can be made from dyed hessian and worked in a bold design in wool or raffia, and are very useful on the verandah furniture or for rough usage.

I have a very useful cloth for the kitchen table and curtains for the boxes I use for cupboards made from hessian which I dyed with Condys and trimmed with cretonne. The hessian being of a fairly open weave tends to suggest some other material than just plain "bag."

Small mats to stand the teapot or other hot dishes upon are made from binder twine and raffia. The raffia is wound round and round the twine and formed into a circle, each round being attached to the previous one by winding the raffia round both at once—at regular intervals.

A useful little whisk for the fireplace can be made from hay bands. The twine can be coloured if desired.

For the making of floor rugs, cushions, &c., from wool and old materials there are many devices. One called "Singercraft" is attached to and used on the sewing machine. If the wool is wound thickly around it the pile sits out instead of lying over as with materials. It is very useful for using up odd scraps of wool.

The "Jewel" needle makes very effective cushions. Finer wool and artificial silk may also be used. Flannel or velour is best for the foundation, as it grips the thread. It is best to have a neutral shade for the background. Clippings are used for cushion fillings. A very effective style is to use two corks on needles and so make short pile or loops. If the material is painted lightly on the wrong side with shellac or thin lacquer, there is no chance of the threads pulling through. Mrs. Queale exhibited samples of each of the articles described. (Secretary, Miss L. Stanway.)

DRESSMAKING.

Miss T. Barnett contributed the following paper at the February meeting of the Laura Bay Branch:—Every girl and woman should be able to do her own dressmaking. Those who are not naturally gifted in this direction are wonderfully catered for by pattern books. The two essential points to remember are accuracy in measurement, cut and fit, and neatness in making, finishing, and pressing.

It is most important that the home dressmaker should know how to take measurements accurately. Not knowing the correct way often results in waste of good material. (1) Neck measurement: Place inch tape round lower part of neck without straining tape. (2) Bust: Place inch tape round body, keeping tape well up under the arms. The tape falls fairly straight across back and lowers slightly in front across fullest part of bust. (3) Length forearm: From where sleeve meets armhole of blouse to wrist. (4) Waist line: Fairly firm around waist of body. (5) Hips: 6in. below waist line, allowing tape slack enough to pass two fingers underneath. (6) Seat: 10in. below waist line, allowing tape slack enough to pass two fingers underneath. (7) Length skirt front: Waist line to length required. (8) Length side skirt: Waist line to length required. (9) Length skirt back: Waist line to length required.

When using a bought pattern, the safest way for the inexperienced worker is to pin all parts of the pattern together and slip it on, making any alterations that seem necessary. If altering the pattern, always remember that the outline of the pattern must not be altered, work from the outside. After the alterations have been made to fit the individual measurements, pin the pattern on the material that has been prepared previously. For cutting out, chalk or tailor tack around the outline of the pattern. When pinning the pattern on the material be sure that the grain of the material all runs one way, otherwise the garment will pull out of shape when finished. Careful cutting makes a wonderful difference to the appearance of a finished garment. When placing the garment together, baste all seams before machining. The flat seam is popular and simple, and is made by joining two pieces of material together right sides facing. This seam must be done neatly—except when under a lining—by clipping or overcasting. For flimsy materials use the French seam, made by machining two pieces of material together on the right side, then on the wrong.

The fitting of the frock is very important. Sleeves are often a worry—never make two sleeves for the same armhole. To determine which sleeve goes into the right armhole, place both sleeves on the table with the seams opposite each other and the under facing up; then each sleeve is for the arm it is in front of. To set in the sleeve, place the seam of the sleeve about 2in. to 2½in. towards the front of the underarm seam of the blouse. This acts in most cases, unless the sleeve is a seam to seam sleeve, then it is placed seam to seam.

If shoulder darts or pleats are used, they should not run with the grain of the material, but with the sleeve line. The turning of a hem should be done invisibly by hand. To do this take a few threads, then insert the needle into the turned hem, pass along about ¼in. before bringing out in the usual way. For finishing off neck and sleeve openings, always cut the material on the bias. (Secretary, Miss T. Barnett.)

NEEDLECRAFT.

Paper read by Miss H. Watt at the March meeting of the Wirrabara Branch, which was attended by 23 members and 14 visitors.

Needlecraft is a homely craft that is practised almost every day, even the sewing on of buttons, or of mending rents, but these are not sought after too willingly. The busy housewife usually soon tires of it—especially women on the land when such work has to be done after the day's work is completed. Even the putting on of patches is an art. How nicely they can be done, and how awkwardly, too. Some patches need a degree of patience to accomplish the task satisfactorily, blending of mending materials, cotton, &c., correctly. Many a tear can be mended so well as to be hardly seen, even when examined closely—by unravelling a thread from the edge of the material and darning it neatly and finely. Our grandmothers and great grandmothers would say this is, coupled with the making of our garments, the main member of the huge needlecraft family, and practice it in our everyday life. It is wise for us to develop our interest in this quarter and not let laziness handicap us in this very necessary craft. Once this is mastered and we are able to make our own garments successfully, then is the time to look for something in the lighter and finer line of stitchery.

KNITTING.

Every young girl should be taught to knit, even if only in a very simple way, by doing plain and purl. Later she will be able to fashion something nice even from this form of knitting. Knitting does not call for so keen an eyesight as fine embroidery or crochet work. Experienced workers with the knitting needles appear to be able to knit quite quickly without looking at their work. Many hours can be passed in this way. The knitting of woollen jumpers, cardigans, singlets, baby clothes, &c., of wool should be encouraged not only because they are so warm and soft during winter and also useful, but it is building up the wool industry, which all Australians should endeavour to do. The buying of Australian made wools not only helps the agricultural community, but gives employment to many hundreds of men and girls. The knitting of home made garments has been practised only for the past 18 to 20 years, and has been the means of developing a vast volume of trade in the manufacture and trade of the woollen yarn.

During the great war knitting came to the fore. It was taught in schools to both boys and girls in many country centres.

At the present time any energetic young lady can have several lacey jumpers and cardigans at a small cost. A jumper I made two years ago has been washed several times, and the wool cost only 1s. The following recipe is ideal for washing woollies:—Two tablespoons of soft soap and one of borax to a pail of water. Put the woollens in very cool water and soak for two hours. Rinse in two or three waters of same temperature, avoid rubbing and do not wring, but squeeze out and dry away from the rays of the sun.

Knitting is also done in silks and cottons, and some charming garments are made, such as jumpers, sox, frocks, scarves, &c.

Needles.

Size 12 needle use 2 ply.
Size 10 needle use 3 ply.
Size 8 needle use 4 ply.

If one is a tight knitter use a size larger needle, and if a loose knitter a size smaller. For small children's clothes use a No. 10 needle for 2 ply; these garments need so much laundering that they soon become closer.

If the knitter has not a tried out pattern for a jumper, try working to a paper pattern or test the working by putting 20 stitches on a needle and working 2in. If this is measured it will give the number of stitches to the inch. Then it is possible to reckon how many stitches to the required number of inches. For singlets use large needles and work them in 2 ply wool. For these loose, open work patterns are preferred, because perspiration and heat shrinks singlets more than laundering. A No. 6 needle is suitable for the work, and once home knitted woollen singlets are worn for winter the bought article will not be purchased.

Second grade wool can be put to many uses—for boys' jumpers and girls' school clothes it is much better, the garments do not shrink so much and they stand up to hard and rough wear. Men's sox also wear much longer if made from the poorer grade wools.

Miss Watt, in order to more clearly explain the merits expressed in her paper, exhibited a fine collection of needlecraft, and kindly offered to show any of her listeners how the various stitches and designs were made. (Secretary, Mrs. E. Harding.)

CHICKEN RAISING.

At the March meeting of the Pinbong Branch, Mrs. F. Rehn read the following paper:—From now on until August is the best time to rear chickens for winter eggs in this part of South Australia. Early chickens receive the green feed that is so necessary for building up their constitutions and this—to develop a strong and healthy bird—is the first essential to plenty of eggs.

First select four of the best two or three year old hens and one good cockerel—preferably a two year old bird. Pen these up and use only their eggs. Be sure and feed plenty of green feed, with liberal ration of grain, shellgrit and stove ashes, and give fresh water daily. After the first week, start saving the eggs and when 10 have been laid, set these under a reliable hen. Turn the eggs each day whilst keeping them, and do not store in too cool a place.

When the chicks are hatched, place them in a pen with their mothers and keep them locked up for a couple of days, carefully looking after them. Then let them out and feed them on broken wheat and screenings. By this method it is possible to raise healthy and robust pullets and cockerels. (Secretary, Miss D. M. Scholz.)

SNOWTOWN BRANCH.

The Snowtown Women's Agricultural Bureau held their first meeting for 1936 on 5th March. The Vice-President (Mrs. A. Andrews) presided over a large attendance. The Secretary (Mrs. A. Hocking) read several greetings from various Branches. Mesdames T. Jenkins and P. H. Wheaton took charge of the meeting and gave very instructive papers on "Cake and Biscuit Making." These ladies also arranged a "Favourite Recipe" Competition. Winners of the prizes were:—Best decorated cake, Mrs. A. V. Wallington, Mrs. A. M. Robertson; small cakes, Mrs. L. V. Hancock; biscuits, Mrs. G. Herbert, Mrs. R. Grigg. The recipes were sent with each entry. A Kitchen Competition was won by Mesdames A. Dyer and J. E. Pridham.

DAHLIA SHOW AT McLAREN FLAT.

The fourth annual dahlia show and cooking competition organised by the Women's Branch of the McLaren Flat Agricultural Bureau was opened in the local Soldiers' Memorial Hall on 21st March by Mr. F. C. Richards (Assistant Secretary, Agricultural Bureau). Although entries in the flower section were not so numerous as last year, Mr. R. G. Bennetts, who adjudicated, said the blooms were a marked improvement on those exhibited in 1935, especially in the decorative dahlia class. The champion flower of the show, the Charm Dahlia "Sunshine," tabled by Mrs. R. Elliott, was a bloom of outstanding quality. Mesdames Robertson and Sauerbier, judges of the cooking section, said the entries were of exceptionally high standard, and it was most difficult to select the winners; the fancy cakes being deserving of special mention.

USEFUL HINTS FOR THE HOME.

The following were given at the 6th February meeting of the Auburn Branch:—To remove coffee stain from a tablecloth, pour boiling water over it while the stain is fresh; if it has dried, soak in glycerine and water. To remove iron rust from cotton goods, rub well with salt and lemon and hang on line. What is the cause of butter being streaky and how to prevent? Butter should be mixed well when washing to prevent it being streaky; salt it and mix well before washing it, then wash in several waters until the right flavour of salt is obtained. To keep onion pickle white, peel with a silver knife, use white vinegar, and add a little alum. Why do not green tomato pickles keep? The vinegar may be faulty. Keep airtight and use plenty of liquid. To give glassware or crystal a brilliant polish, wash in soapy water or add a little cloudy ammonia to the water and polish well. What will get rid of bull ants? Waste oil put over the holes where they nest drives them away. A good cure for foot ache:—Bathe the feet in hot water and methylated spirits, or methylated spirits and glycerine mixed in equal parts and rubbed well in will give relief. Castor oil rubbed well into the soles of feet is also good. (Secretary, L. J. Dennison.)

SUMMARY OF REPORTS RECEIVED.

Branch.	Date of Meeting.	Attendance.	Subject.	Secretary.
			WOMEN'S BRANCHES.

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, 1936.

Eyre's Peninsula (West), at Ceduna (O'Loughlin Branch), Wednesday, 1st July (Mr. E. R. Pfeiffer, Ceduna).

Upper North, at Eurelia, Wednesday, 15th July (Mr. E. S. Wall, Eurelia).

Murray Lands (West), at Karoonda (Yurgo Branch), Tuesday, 21st July (Mr. H. M. McKenzie, Yurgo).

Pinnaroo Line, at Pinnaroo, Thursday, July 23rd (Mr. H. L. Badman, Pinnaroo).

Eyre's Peninsula (East), at Kimba (Kelly Branch), Tuesday, 4th August (Mr. F. R. Illman, Box 64, Kimba).

Southern, at Inman Valley, Thursday, 20th August (Mr. S. F. Hacklin, Inman Valley).

Hills, at Cherry Gardens, Thursday, 27th August (Mr. A. R. Stone, Cherry Gardens).

Murray Lands (East), at Alawoona, Tuesday, 6th October (Mr. Angus Thomson, Alawoona).

Eyre's Peninsula (Central), at Minnipa, Friday, 23rd October (Mr. H. E. Broad).

Fruit (non-irrigated), at Greenock, Tuesday, 3rd November (Mr. A. Schubert, Greenock).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Pruning Competitions.

River Murray Branches—

Berri, 23rd June.
Barmera, 24th June.
Moorook, 25th June.
Cadell, 30th June.
Waikerie, 1st July.
Mypolonga, 6th July.
Championship at Mypolonga, 7th July.

Lower North—

Greenock, 19th June.
Watervale, 22nd June.
Lyndoch, 4th June.
Williamstown, 26th June.
Koonunga, 30th June.
Light's Pass, 1st July.
Lone Pine, 3rd July.
Championship at Greenock, 9th July.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Northern Yorke Peninsula, Field Trial and Show—Bute, Wednesday, 26th August.
Saddleworth, Saturday, 19th September.
Wudinna, Wednesday, 23rd September.
Waikerie, Saturday, 26th September.
Balaklava and Dalkey, Saturday, 26th September.
Eudunda, Wednesday, 30th September.

Laura, Wednesday, 30th September.
Kapunda and Light, Saturday, 3rd October.
Wirrulla, Saturday, 3rd October.
Burra Burra, Saturday, 3rd October.
Karoonda, Wednesday, 7th October.
Murray Bridge, Thursday, 8th October.
Blyth and Kybunga, Saturday, 10th October.
Loxton, Wednesday, 14th October.
Kimba, Wednesday, 14th October.
Colton, Wednesday, 14th October.
Penola, Wednesday, 14th October.
Strathalbyn, Wednesday, 14th October.
Tailem Bend, Saturday, 17th October.
Mannum, Saturday, 17th October.
Paruna (Brown's Well), Saturday, 17th October.
Maitland, Wednesday, 21st October.
Pinnaroo, Wednesday, 21st October.
Mount Gambier, Wednesday and Thursday, 21st and 22nd October.
Willunga, Thursday, 22nd October.
Clare, Saturday, 24th October.
Port Elliot, Saturday, 24th October.
Kingston (South-East), Saturday, 24th October.
Minlaton (Central Yorke Peninsula), Wednesday, 28th October.
Tatiara (Bordertown), Wednesday and Thursday, 28th and 29th October.
Yankalilla, Saturday, 31st October.
Millicent, Saturday, 31st October.
Mount Barker, Saturday, 7th November.
Woodside, Saturday, 14th November.

Pork Trade.

Writing from London on 14th May, the Agent-General and Trade Commissioner for South Australia (Mr. C. F. G. McCann) states that inquiries are in existence for June-July shipments of South Australian pork, at prices that will probably show a profit to breeders. The demand for Australian and New Zealand frozen pork is a growing one, and each month one notices that gradually the deliveries are becoming standardised in type, though varied in breeding. Preference is in evidence in inquiry and demand for white and chestnut-haired pigs, whose outward appearance, when hung on hooks at Smithfield, is decidedly more attractive. Possibly this will be minimised when greater proficiency in scalding black-haired carcasses is attained. The maintenance of uniformity in the heat of scalding water is imperative, otherwise shaving is bound to depreciate the appearance and value of the carcasses. The Danes, Lithuanians, Canadians, and Argentinians all use cleaning machines and singers and, in consequence, the pork and bacon have a greater appeal to the eye of the buyer, though in actual flavour of meat, either cured or fresh, our pork compares more than favourably.

Tariff Changes.

The Tariff proposals tabled in the House of Representatives provide for the following duties on lubricating oil:—The British preferential duty on mineral lubricating oil is reduced by ½d. per gallon; the new intermediate rate will be the same as the existing general rate; and the general rate will be increased by 1½d. per gallon. The new rates are:—

British	3½d. per gallon
Intermediate	4½d. per gallon
General	6d. per gallon

The increase in the general tariff is intended to give scope for treaty making.

Our Wheatgrowing Areas—Profitable and Unprofitable.

On page 1208 (first paragraph) of the article by Professor Perkins on "Our Wheat Growing Areas—Profitable and Unprofitable" the reference to the county should be Albert and not Alfred. The corrected paragraph is as follows:—

> In county Albert, which lies to the east of county Alfred and is partly within and partly without Goyder's Line, there were eight Hundreds out of thirteen which averaged less than 6bush. per acre in the 20 year period under consideration, namely:—Bakara (5.83bush.), Bandon (5.56bush.), Cadell (5.04bush), Holder (4.76bush.), Mantung (5.40bush.), Moorook (5.45bush.), Paisley (5.75bush.), and Waikerie (4.54bush.), all of which lie outside the line and do not appear to have justified themselves as Wheat growing hundreds. Of the hundreds lying outside the line Murbko above had a mean yield of 6bush. or over, namely, 6.52bush. per acre.

Urrbrae Agricultural High School.

The Urrbrae Agricultural High School which was recently visited by members of the Advisory Board of Agriculture is built on land made available by the late Mr. Peter Waite, near the terminus of the Fullarton car line.

Situated at the foot of the hills, with the Waite Research Park on one side and in ample grounds of its own, its surroundings are favourable both as regards health and opportunities for agricultural development.

At present it is a day school, but the Fullarton car is convenient, and good boarding accommodation can be obtained in the vicinity.

A general education is provided in addition to Agriculture, the curriculum including the following subjects:—English, Mathematics, Arithmetic, Bookkeeping, Botany, Chemistry, and Agriculture (Latin if needed). Students are encouraged to sit for the Public Examinations on the above subjects. Special pains have been given to planning a course suitable for a lad who desires to become a primary producer, and students are encouraged to go on to Roseworthy College.

The Agricultural course includes the study of Crops, Animal Husbandry, and Farm Mechanics. In the school orchard and plots there are opportunities for pruning, spraying, and other practical work. The land available for school experiments is about 30 acres.

Valuable assistance is obtained from the Waite Research Institute which adjoins the school, and visits are made to places of agricultural interest. Pruning, milk testing, and stock judging are important features of the course of instruction.

Evidence that the school is providing a suitable education for country lads is the fact that the attendance is steadily growing, and the following widely-separated centres are represented by scholars:—Kangaroo Island, Willunga, Wynarka, West Coast, Yorke Peninsula, Snowtown, and Millicent. These lads board in the neighbourhood of the school, and others travel to and fro daily by service car from the Hills and other districts.

Imperial Fruit Show.

The Imperial Fruit Show and Canners' Exhibition will be held in Renshaw Hall, Liverpool, on October 30th-November 7th, 1936. The classes open to competition by Australian exhibitors include citrus fruits, apples, canned fruits, and honey. Except where exhibits are to be drawn from stocks held in the United Kingdom, citrus and canned fruits classes, all entry forms and fees must reach the office of the Department of Commerce, Canberra, by August 22nd. Amounts so remitted should include the cost of remitting such fees to London at the current rate of exchange. Oranges and grapefruit are to be judged in London on July 21st and 22nd.

The Imperial Fruit Show offers to Australian producers a good opportunity to demonstrate the high quality of their products, and in past years Australian exhibitors have achieved marked success at this show.

A copy of the prospectus is available for inspection in the library of the Department of Agriculture.

Production of Butter and Cheese.

The following returns show the production of butter and cheese in South Australia since December 1st, 1935:—

1935.	Butter. Lbs.	Cheese. Lbs.
December	1,642,062	807,281
1936.		
January	1,436,611	576,797
February	1,042,250	444,820
March	879,379	411,593

AGRICULTURAL INQUIRIES.

[Replies supplied by W. J. Spafford, Director of Agriculture.]

Viability of Seed Wheat.

Sutherlands asks:—"What is the annual decrease in the germinating power of stored Seed Wheat."

Reply—Wheat Seed varies a good deal as to its length of life according to variety, season, soil, and other factors. Sometimes a sample will retain a high germinating power, of say 90% or over, for 7 or 8 years, and then the percentage of grains capable of germinating will get less very rapidly, whilst other samples gradually lose their germinating power year after year for 9 or 10 years. Occasionally a sample will contain a few grains that might live for 20 years or so, but most grains in practically all samples die within 10 years. An instance taken from the records of the Danish State Seed Testing Station, where the life of most of the important Agricultural seeds has been tested, shows the life of wheat seeds to be:—1st year, 92% germination; 2nd year, 95% germination; 3rd year, 87% germination; 4th year, 88% germination; 5th year, 74% germination; 6th year, 78% germination; 7th year 24% germination; 8th year, 3% germination; 9th year, Nil.

Dews and Soil Moisture.

Miltalie Agricultural Bureau asks:—"When a heavy due falls, does it add moisture to the soil?"

Reply—"When the moisture settling on plants and soil as dew is derived from adjacent water, as the sea, or extensive lakes, then it is new water for the soil, but most dews are the result of water that has evaporated from the soil being redeposited either on the actual soil from which it came or from closely adjacent areas. As most of the dew evaporates soon after the sun comes out, dews generally mean a direct loss of moisture from soils in the neighbourhood."

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

Horse with Swollen Fetlocks.

Hon. Secretary, Agricultural Bureau, Whitwarta, asks cure for horse with legs swollen from the fetlocks upwards.

Reply—The swelling (oedema) of the legs is often associated with debility, "greasy heels," standing too long on hard floors, and may be the result of heart disease, etc. It is advised that you keep the horse in good condition, and if swelling occurs give a purgative drench of—raw linseed oil, 1½ pints; oil of turpentine, 2ozs. Subsequently give 1 teaspoon of powdered nux vomica night and morning for 14 days. To give, mix with treacle and smear on tongue.

Cramp in Pigs.

"Cleve" reports:—(1) *Pigs with cramp in hindquarters.* (2) *Horse which loses control of hindquarters.*

Replies—(1) Such symptoms are usually associated with a deficiency of vitamins and possibly lime in the diet. Treatment:—From a chemist obtain 8ozs. of good quality cod liver oil, and twice a day for 15 days give affected pigs 1 teaspoon. Instead of superphosphate, give the following lick:—Slaked lime, 2 parts; common salt, ½ part; mix well. Warning—It is essential that the lime be well slaked by exposure to air. Give greenfeed if available, and report progress in three weeks' time.

(2) The symptoms exhibited may be the result of an injury such as a fall or blow, or may be the result of eating damaged fodder, which causes a disease known as Botulism, the characteristic symptoms being a paralysis of nerves governing movement. It is suggested that the following treatment be tried:—Keep the horse in a stall for at least a month, giving no exercise. Change the feed if possible, supplying chaff from another source. Obtain from a chemist the following medicine:—Take strychnine hydrochloride, 10 grains; white sugar, 2½ozs. Divide into 20 powders. Directions:—Label "Poison." One to be given in a little food or dissolved in a cup of water twice a day for 10 days, then stop.

CHICKEN POX.

"Cleve" reports poultry with swollen heads with sores, scabs and eyes badly affected. Replying to this question, Mr. C. F. Anderson (Government Poultry Expert) says:—

"The trouble with the poultry is chicken pox. Any of the following treatments are generally satisfactory:—

1. Obtain from the chemist a 10 per cent. mixture of carbolic and glycerine, and paint the affected parts with this mixture.
2. Obtain a knob of washing blue, wrap in cheese cloth or similar material, moisten same, and rub it over the affected parts.
3. Paint with equal parts of iodine and water.

Thoroughly cleanse out the sleeping quarters, and spray twice a week with a 10 per cent. solution of kerosine and water."

SLIPPING BELTS.

Replying to the Secretary of the Sutherlands Branch of the Agricultural Bureau, who asks what can be done to prevent machinery belts from slipping, Mr. H. R. Nourse (Farm Mechanic at Roseworthy Agricultural College) says:—

"Both rubber and canvas or balata belts are much used on farms. Cotton, rubber or balata belts should not require very much dressing; if they should dry, a small amount of castor oil smeared on the belt will help.

There are several preparations on the market, all of which are useful; but they should be used very sparingly. These are usually sold in bars of about the consistency of soap, and are applied to the belt while it is running.

Neatsfoot oil might not harm a cotton belt, but it should not be used on rubber or balata; it is, of course, good for leather.

The cause of belt trouble with farm machines is mostly due to the fact that they are too light for the work they have to do. Other causes of trouble are:—(1) Belts too narrow; (2) belts too thin; (3) belt speed too low; (4) pulley too small; (5) incorrect alignment; (6) uneven speed of engines.

The best cure for most troubles is to use leather of double thickness, or, if of rubber or balata, use 5-ply or 6-ply."

THE AGRICULTURE OF NEW ZEALAND.

[By R. C. SCOTT, Supervisor of Experimental Work.]

One of the chief impressions gained after a tour of the Southern Hemisphere by the present Director of Agriculture (Mr. W. J. Spafford), and "Yattalunga" (Colonel C. P. Butler) of the Advertiser, was that South Australia had much to learn from the agriculturists of New Zealand. They were of the opinion that particularly in pasture management and animal husbandry on small holdings the New Zealand farmer showed special skill.

Consequently Colonel Butler conceived the idea that if a party of South Australian primary producers could be organised to tour the Dominion and see for themselves the methods adopted and the results achieved, much good would result.

The matter was taken up with the New Zealand Tourist Bureau, and as a result a party of 16 men drawn from different districts of the State made the visit during January and February of this year.

They landed at The Bluff on the southern end of South Island, and after a tour of the Southland, Otago and Canterbury Provinces, proceeded to Wellington in the North Island, which is the capital city of New Zealand. From there the party travelled through the Hawke's Bay district along the edge of the Gisborne area, circled around the Auckland Province and across Taranaki, finally returning to Wellington, from whence they boarded the boat for Australia.

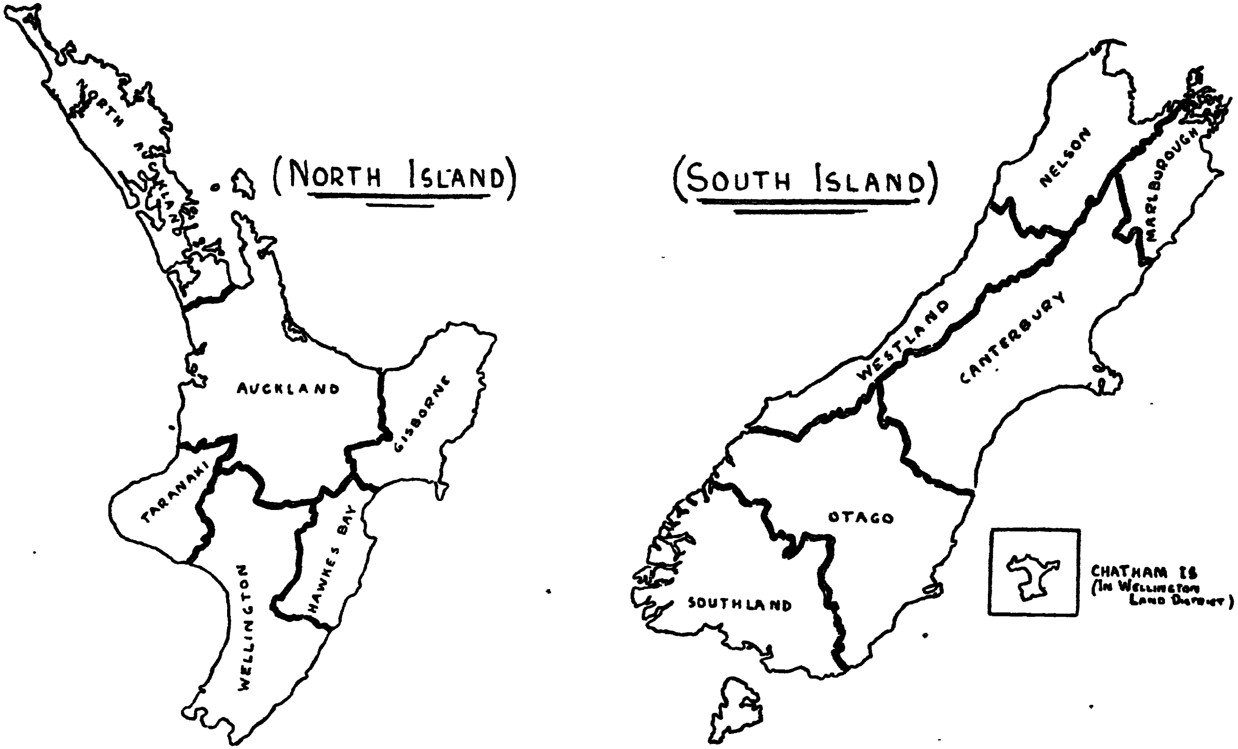
In all districts opportunity was afforded of inspecting the properties of successful farmers and observing the methods adopted. Agricultural educational institutions, meat works, dairy factories, &c., were visited, and a most interesting and instructive time was spent.

The following remarks will give some idea of the agricultural conditions of the country, but in addition reference to the scenic beauty of the land is also necessary. The view never became monotonous; even that area described as a plain, namely the Canterbury Plain, is traversed by numerous streams with glorious mountains in the background, and delights the eye of the visitor. Throughout both Islands the mountains, the lakes, the rivers, the broad valleys, the neatness of the homesteads, fertility of the country and other factors all combine to make New Zealand a most beautiful land, well worthy of visiting from that point of view alone.

STATISTICS OF NEW ZEALAND.

The total area of New Zealand including all small islands is 104,015 square miles. Consequently, as South Australia totals 380,070 square miles, New Zealand is only a little more than one quarter the area of this State.

The North Island is slightly larger than the South, the areas being 58,092 and 44,281 square miles respectively.



Map 1

Map 2

Land Districts of New Zealand.

[From *Agricultural Organisation in New Zealand.*]

Particulars showing how the land is utilised are given in the following table:—

Land Utilisation in New Zealand, 1934-35.

	Acres.	
Sown grasses, clovers, lucerne	17,388,174	
Plantations (pines)	760,420	
Green fodder	682,828	
Grain crops	641,205	
Fallow land	115,832	
Private gardens, &c.	81,694	
Orchards	25,087	
Plantations (eucalypts, &c.)	21,264	
Market gardens	7,284	
Tung trees	4,780	
Nurseries	1,276	
Hop vines	590	
Grape vines	433	
Passion fruit vines	244	
Total area of cultivated land		19,502,519
Tussock and native grasses	14,184,044	
Fern scrub, &c.,	4,079,763	
Virgin bush and forest	3,284,154	
Barren land	1,881,256	
New Zealand flax	72,828	
Total area of unimproved land		23,602,040
Reserves for public purposes, &c.	18,132,871	
Rivers, lakes, &c.	5,153,766	
		23,286,637
Grand total area		66,390,196

From the foregoing details it will be noted that practically one third of the total area of New Zealand is cultivated land, one third is occupied but is still classed as unimproved, whilst the remaining third includes areas within Borough boundaries, land unfit for settlement and other reserves.

Of the cultivated area 89 per cent. is devoted to sown pastures including lucerne, and a further 3.5 per cent. is under green and root crops. Consequently almost 93 per cent. is entirely devoted to the grazing of animals, whilst there is a further 14 million acres of tussock and other native pasture which must be included in the total area under grass.

AREA OF HOLDINGS.

The average farm holding in New Zealand is small, 75 per cent. being less than 320 acres, 63 per cent. less than 200 acres, and 45 per cent. less than 100 acres in area.

On the other hand there are a number of pastoral runs which exceed 50,000 acres in extent. These are mainly situated in the South Island and include the poorest of the occupied land. However, large areas are exceptional and only 8.3 per cent. of the holdings exceed 1,000 acres.

The average size of farms varies according to the class of agriculture practised, and is approximately as follows:—

	Acres.
Dairy Farms	105
General Mixed Agriculture	140
Mixed Dairy and Sheep Farming	400
Sheep Farming	425
Sheep and Cattle Grazing	1.700

CLIMATE.

New Zealand possesses a climate which is cool and moist, whilst there is no wide variation in temperature or rainfall either from season to season or from year to year. It is situated in the Temperate Region, and is in the zone of prevailing westerly winds. These winds are broken by striking the mountains and hilly country which generally obtains, with the result that there is frequent disturbance of atmospheric conditions, and the rain periods are not of long duration. They are spaced by intervals of sunshine, and it is this frequency of sunshine following the rain which favours agricultural production and the health of livestock. Other advantages are that they lead to evaporation, making the pastures better underfoot, they reduce the area of swamp and peat land which would otherwise occur, and lessen the liability of frost and atmospheric conditions favourable to the development of rust in cereal crops.

On the other hand the wheat varieties planted must necessarily be of hard threshing nature, shelters must be provided for livestock in the field, whilst the native tussock grass is of a tough fibrous nature.

Over the greater part of New Zealand the annual rainfall lies between 25in. and 60in., but the area averaging less than 25in. is relatively small and is mainly confined to portions of Central Otago and the Canterbury Plain in the South Island.

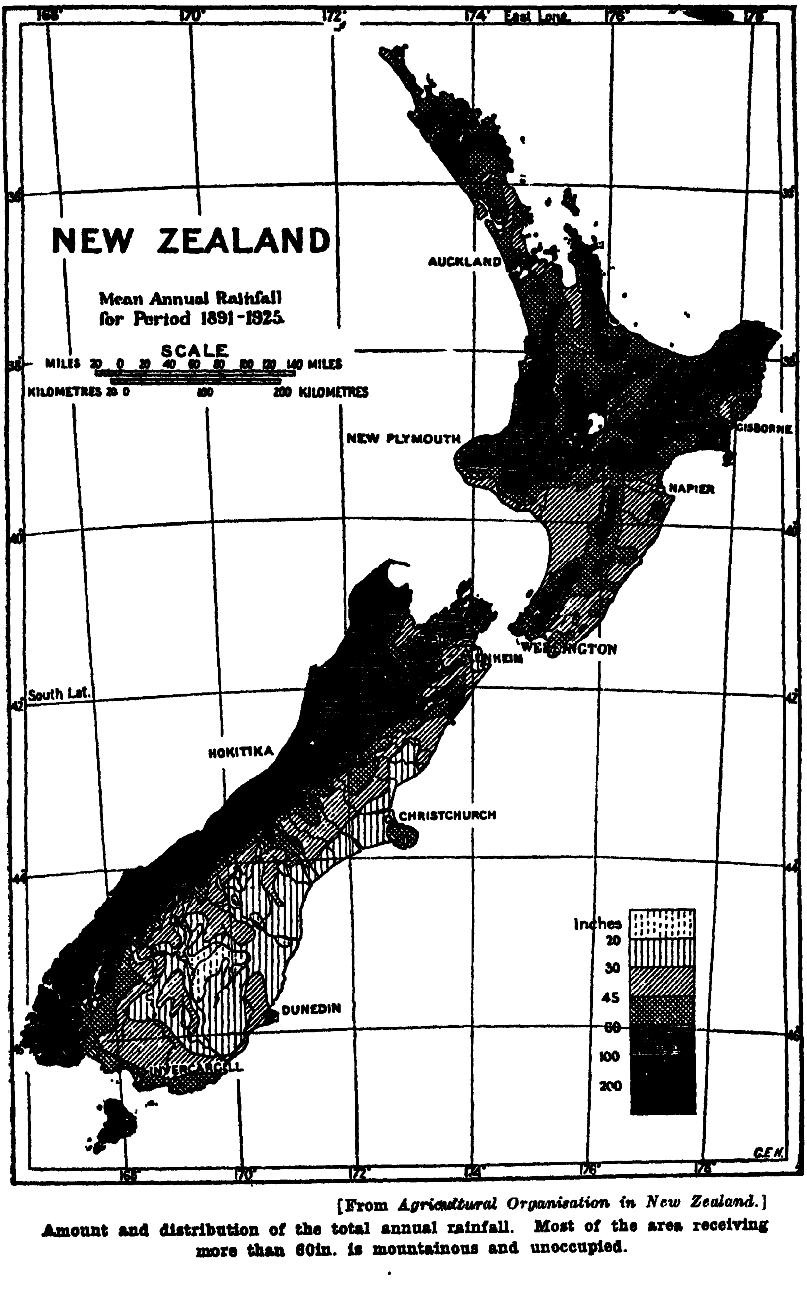
It is chiefly the mountainous and therefore the unoccupied land which receives more than 60in. of rain per annum, with some of the highest altitudes recording over 200in.

In the following map the mean total rainfall is shown, and it is interesting to note that the country shielded by mountains from westerly and north-westerly winds receives the lowest fall and the extreme is 13in. annual precipitation for an area lying midway between Dunedin and the Southern Alps. There is rarely appreciable difference in the amount of rain recorded in any one district from year to year, and although dry periods or excessively wet years may be experienced they are not common. However, it is the distribution of the rainfall throughout the year which is of interest to South Australians, who are familiar with a climate under which the great bulk of the rain falls in the winter months and relatively little in the summer. North of Auckland there is some variation between the winter and summer falls, but over the remainder of the Dominion the difference is not great, and the amount registered is fairly even for each month of the year.

The distribution at a few of the main centres is shown in the following table:—

Rainfall Distribution in New Zealand.

Month.	Auckland.	New Plymouth.	Napier.	Wellington.	Christchurch.	Dunedin.	Invercargill.
	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.	Ins.
January	2.74	4.20	3.02	2.81	2.20	3.42	3.96
February . ..	3.04	3.81	2.76	2.67	1.71	2.71	3.11
March	3.01	3.75	3.16	3.11	1.98	2.94	3.89
April	3.54	4.54	2.78	3.53	1.85	2.74	4.14
May	4.66	6.21	3.71	3.98	2.53	3.11	4.34
June	4.95	5.98	3.51	4.19	2.68	3.16	3.63
July	5.07	6.46	3.82	4.71	2.69	3.01	3.28
August	4.23	5.46	3.50	3.82	1.85	3.09	3.25
September ..	3.71	5.06	2.22	3.11	1.74	2.75	3.27
October	3.72	5.47	2.23	3.41	1.69	3.12	4.50
November ..	3.31	4.82	2.43	2.90	1.92	3.25	4.41
December ..	2.91	4.28	2.31	2.84	2.15	3.54	4.07
Total . ..	44.89	60.04	35.45	41.08	24.99	36.84	45.85



[From *Agricultural Organisation in New Zealand.*]

Amount and distribution of the total annual rainfall. Most of the area receiving more than 60in. is mountainous and unoccupied.

Examination of these figures shows that the rainfall is very evenly distributed over the 12 months. Even at Christchurch where the annual fall is only 24.99in., that is to say comparative with that recorded at a number of centres in this State, the lowest rainfall month is October with 1.69in., an amount which is quite appreciable. As a consequence perennial plants are not subject to severe summer drought, whilst as there is no record of a shade temperature of 100° F. ever being recorded, with readings of 90° F. very rarely obtained, such plants are able to carry through from season to season without check and provide the evergreen pastures for which New Zealand is famed. Periods of dry and warm weather may occur, and at times spells of wet weather may interfere with haymaking and harvesting operations, but these are exceptional and generally speaking the Dominion enjoys a climate highly suited to the development of pastures, with satisfactory grain crops only possible in the medium rainfall localities. As a result the Canterbury Plain (Christchurch) is practically the granary for New Zealand.

SOILS.

The soils of the cultivated area of New Zealand are naturally fertile, their chief deficiencies being phosphoric acid and lime.

In the North Island very large areas are covered by volcanic ash forming extremely valuable pasture country. These lands are mainly situated in the Taranaki, Wanganui and Waikato districts, whilst although the wonderfully high producing Hawke's Bay area is in the volcanic ash region, these soils consist chiefly of an admixture of volcanic ash and alluvial material washed down from the higher levels by surrounding rivers. This has resulted in the formation of very fertile land with high carrying capacity for stock, whilst on the wide alluvial flats many apple orchards are situated.

Over the remainder of the North Island there is a great range of soil type varying from sands north of Auckland, poor pumice in the central regions, and fertile silts in the southern land. However, generally throughout the country there are broad alluvial plains and swamps bordering the rivers.

In the South Island the most important soil is that of the Canterbury Plain. This is of alluvial nature, varying from rich loam overlying clay to poor coarse sandy material overlying gravel. Naturally this latter type is not very fertile and is mainly situated on the fringe of the plain near the foothills. Although this class represents a considerable area it is small as compared with the full extent of the Canterbury Plain itself, which is some 150 miles long by about 40 miles wide. Consequently the greater part is really good quality soil which readily responds to cultivation and planting.

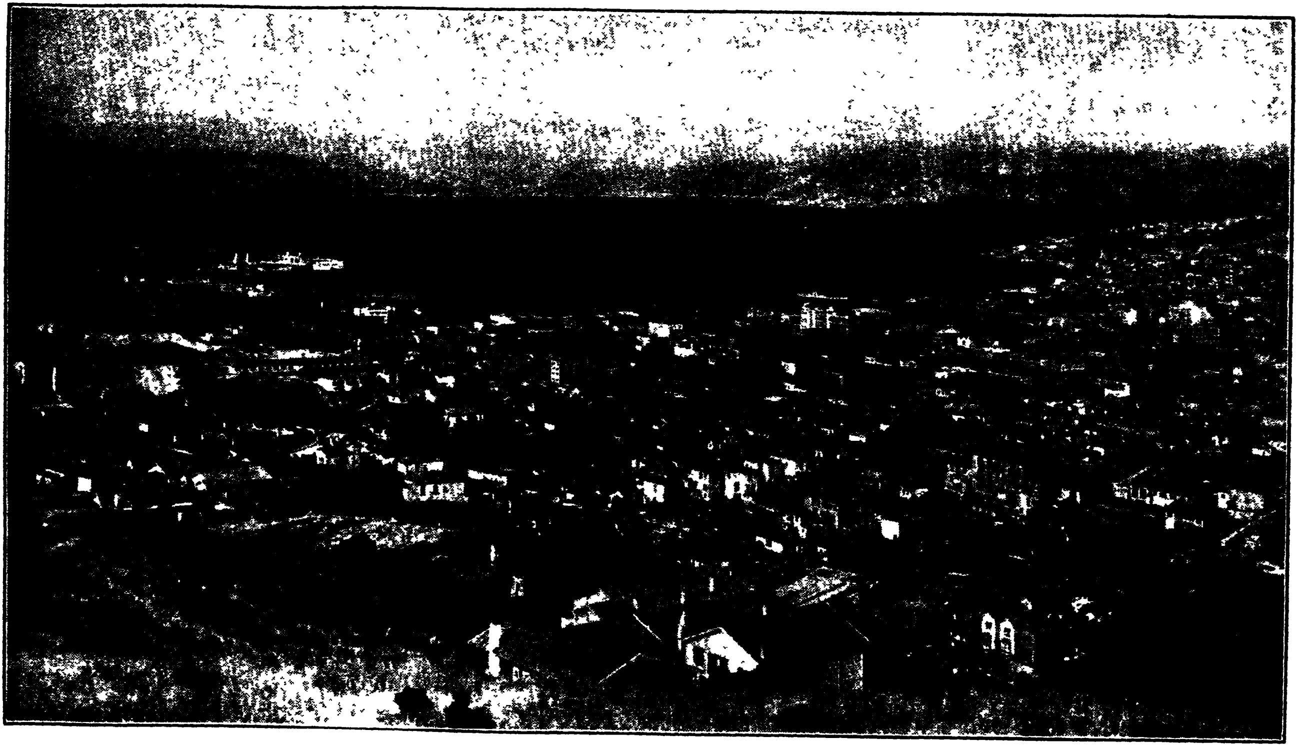
Generally throughout the Southern Province the soil is shingly on the higher levels, deep loam over clay on the undulating country, alluvial soil over gravel on the flats and river beds, with swamps at the river mouths.

The more mountainous country varies from heavy silt to stony loams and gravelly basins to greyish sand on portions of the West Coast. Reviewing the position, therefore, it may be said that the soils of the cultivated area of New Zealand are highly productive and consist of volcanic, alluvial and a mixture of volcanic and alluvial types, together with areas of rich loams and good sands, whilst in the occupied but not cultivated area the land is rougher and more stony and varies from stony loams and gravelly depressions to soils of both heavier and lighter texture.

PASTURES OF NEW ZEALAND.

The pastures of New Zealand may be divided into two main groups, namely sown pasture and natural pasture.

The former is represented by over 17,000,000 acres and the latter by a little more than 14,000,000 acres, making a total of almost 42,000,000 acres devoted to grassland farming out of the 43,000,000 acres occupied.



[Photo. New Zealand Tourist Bureau.]

Wellington City and Harbour: Wellington is the capital of New Zealand and has a population of 147,000 inhabitants

The natural pasture is generally referred to as tussock country, although over large areas finer leaved grasses and other herbage are associated with the tussocks.

At the present time by far the greater area of this class of grassland is to be found in the mountainous and dryer lands of the South Island. There are three main types of tussock, namely the Poa, Festuca and Danthonia classes, and any of these may predominate according to the conditions of soil, moisture and altitude.

The Danthonia tussock country, particularly on the lower levels, is generally capable of improvement by the planting of better pasture varieties, together with adequate liming, manuring, &c. As a rule the natural pasture land is held in large areas and on the average is capable of maintaining a sheep to about five to seven acres. Little is done in the way of top-dressing and the properties are managed on very much the same lines as the pastoral holdings in Australia. With regard to the sown pastures the most striking feature is the density of the herbage. There are practically no bare patches present, such as is regularly the case in our pasture lands where the summer killing of shallow rooted plants is prevalent.

[Photo. by H. M. Westwood.]

Members of the party at the Normanby Co-operative Cheese Factory, Hawera. 1,142 tons of cheese were manufactured in this factory in 1935, which is said to be the largest amount made under one roof in the world. The milk supplies were drawn from a radius of 2½ miles.

It is the density of pasture which explains the high carrying capacity of many farms, and in the better lands of the North Island instances of eight sheep or approximately a cow per acre were repeatedly met with.

In establishing pastures European species of grasses and clovers are invariably used; the actual varieties and mixtures depending upon the type of farming practised and the class of soil or climate obtaining in the district.

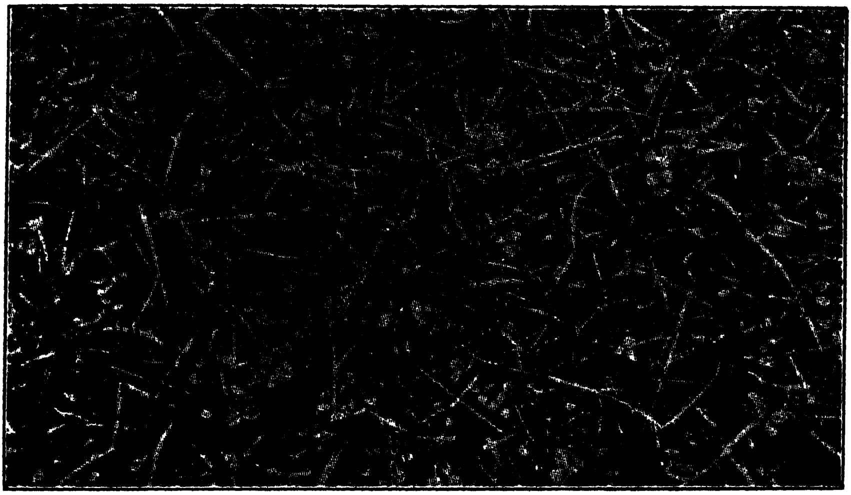
Where the stand is only intended to be of a temporary nature, such as would be the case if a hay crop was required, or where the land was only partially cleared from bush growth or reclaimed from peat swamp, rapid growing varieties are utilised. Typical seeding for such requirements is 30lbs. Italian Rye Grass and 6lbs. of Red Clover per acre.

Sometimes the application of Italian Rye Grass is halved and 15lbs. of Western Wolth's Rye Grass included. The latter is a leafy selection from Italian. It is a quicker grower in the first season, but tends to thin out to a greater extent in the second.

Again in the damper or more saline soils Alsike may replace the Red Clover. Short rotation pastures are adopted in the mixed farming areas of the South Island, occupying the land for three to four years and working in rotation with cereal and root crops. The climatic conditions of these districts do not favour long term permanent pastures, whilst it is also necessary to supply some additional feed in the winter, which means cultivation and the planting of special fodder crops for the purpose. A regular pasture mixture for a short rotation stand is:—

25lbs. Perennial Rye Grass.
10lbs. Italian Rye Grass
4lbs. Red Clover
2lbs. White Clover

On the Canterbury Plain there is a tendency for rather lighter seeding, making a total dressing of from 30 to 35lbs., but on the other hand in the Southland Province it is usual to increase the amount of seed, adding about 6lbs. of Timothy and 2lbs. of Alsike per acre.



A close up view of an excellent permanent pasture mixture consisting chiefly of Perennial Rye Grass and White Clover.

Truly permanent or long rotation pastures are planted on the better type soils of the wetter districts of both Islands, but the bulk of the permanent pasture land is to be found in the Norh Island. A typical seed mixture is as follows:—

	Lbs.
Perennial Rye Grass	25
Cocksfoot	10
White Clover	3
Red Clover	3

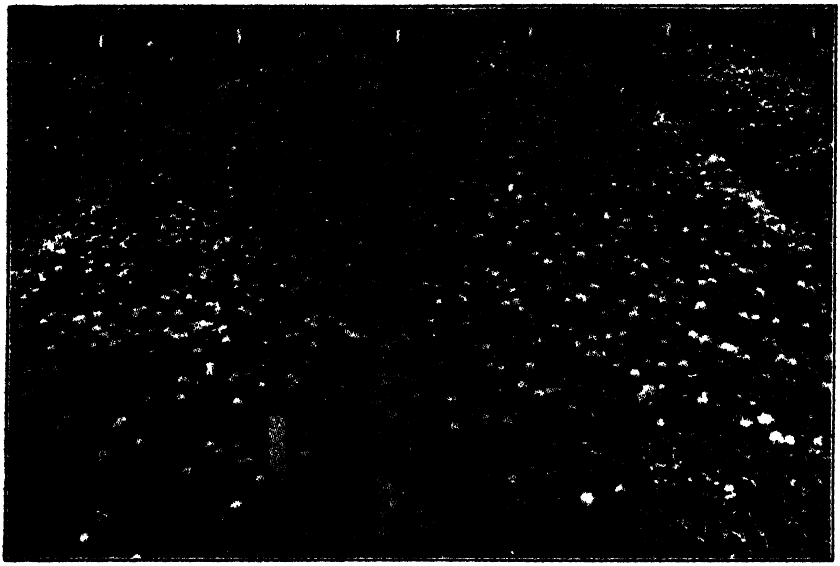
Naturally there are variations of this mixture according to circumstances, the chief of which so far as the high producing pastures of the Auckland and Taranaki Provinces are concerned is the inclusion of 5 to 6lbs. of Paspalum seed and a reduction in the quantity of Cocksfoot planted. In fact Paspalum is regularly included in the seeding mixtures for all districts enjoying relatively mild winter conditions.

Other exceptions to what may be regarded as the standard mixture for permanent pastures are:—The addition of about 6lbs. of Italian Rye Grass where quick early growth is desired, about 2lbs. of Crested Dogstail for undulating country and particularly for sheep grazing, about 3lbs. of Timothy for rich soils inclined to wetness, and about 4lbs. of Meadow Foxtail together with 2lbs. of Rough Stalked Meadow Grass for fertile land which is too wet for the successful establishment of rye grass. Such seeding is at the expense of the Perennial Rye or Cocksfoot, whilst for reclaimed salty swamps the quantity of Red and White Clover is reduced and about 2lbs. each of Alsike and Strawberry Clover are included.

On relatively new land or that of lower fertility the seeding mixture frequently includes such varieties as Brown Top, Chewings Fescue, Danthonia pilosa, Kentucky Blue, Lotus Major, Poa aquatica, Prairie Grass, Yorkshire Fog and Tall Fescue.

Brown Top thrives on the medium class soils in the hilly country, which are of a wet heavy nature, and Yorkshire Fog does well in the wet, peaty lands.

In recent years Subterranean Clover has come into prominence for the friable, open textured soils, particularly those situated on the fringe of the Canterbury Plain, whilst it is fairly often included in the permanent pasture mixture for other districts. In this case it is added at the rate of 1 to 2lbs. per acre and is favoured because of the amount of growth produced in the winter and early spring. It was stated that in the Hawke's Bay district the earliest maturing lambs were secured from those pastures including Subterranean Clover in the mitxure.



[From *New Zealand Journal of Agriculture.*]

White Clover plots at the Plant Research Station, Palmerston North. New Zealand Certified White Clover on the right. This is an outstanding type, superior in every way to all other strains. Certified seed is available and is being freely planted. Similar work has been done in the production of New Zealand Certified Perennial Rye Grass, Cocksfoot, Red Clover, &c.

SEEDING OF PASTURES.

The New Zealand farmer has quickly recognised the importance of good seed, and rarely plants other than the best. At the Plant Research Station at Palmerston North much pasture selection work has been done and improved strains of Rye Grass, Cocksfoot, White Clover, Red Clover, Brown Top, &c. isolated and seed supplies built up.

DESIGNED AND BUILT AT DAGENHAM, ENGLAND

The result has been the development of an excellent strain of Perennial Rye Grass of great persistency and yielding an abundance of leafy growth, and of a strong growing broad leaved White Clover of high productivity. As these are the two most important pasture plants in the Dominion, the work of selection and certification of seed of the best strain is leading to improvement in the permanency and yield of the grazing areas. Every care is taken in the preparation and planting of the land, and this thorough treatment is a direct contrast to much of the pasture seeding in this State where many farmers expect fodders to estabish themselves satisfactorily with much poorer preparatory tillage than they would give to crops of a more temporary nature. The soil is worked to a fine firm seed bed, and if there is neglect in this direction an unsatisfactory germination is likely to follow. The seeding period extends from spring to autumn, the majority of pastures in the warmer districts being planted in February or March, and where autumn frosts are common, spring sowings are generally adopted. The amounts of seed planted are much heavier than is customary in South Australia, and are probably associated with the favourable summer weather and the fact that the rainfall is so regular that shallow rooted plants are able to carry through. Thick seeding provides for a dense sward which can be maintained from season to season, whereas with us, perennial plants have to be relatively widely spaced and allowed to develop an extensive root system in order to be able to survive the long, hot, dry periods frequently experienced in our climate.

Superphosphate is regularly applied at seeding, usually alone but occasionally in conjunction with bone dust. The amount varies from about 1 to 3cwt., whilst one instance was met with in the Waikato district where 3cwt. of superphosphate and 2cwt. of bone dust were drilled in with the seeding mixture.

MANAGEMENT OF PASTURE.

Annual top-dressings of fertiliser are applied to pastures, and more information in connection with manures will be given under that heading.

After establisnment, the pasture is permitted to reach a height of 4 to 5in. before feeding, and the principle of rotational grazing is fairly closely practised. The intervals between grazing are rather shorter in the case of sheep than cattle, and the herbage is kept more closely grazed. However, this close grazing is not allowed to continue for more than a few days, since severe feeding-off limits the production of pasture.

Well grazed pastures may be spelled for about three weeks without appreciable loss in the feeding value of the produce, and this is the general practice with dairy cattle, but in the case of sheep, particularly ewes and lambs, the change from one class of fodder to the flush of growth in a new field has a bad effect upon the stock themselves, and with sheep, weekly resting periods or even less are not too short.

So as to permit regular grazing most farms are closely sub-divided, and properties consisting of from 12 to 30 fields are by no means uncommon.

An illustration of the handling of sheep under an intensive grazing system was gained at Marton in the North Island, where the farm has been divided into 14 fields each of seven acres. This area carries 900 breeding ewes and the lambing is consistently about 100 per cent.

From about February, when all lambs have been sold, the ewes are held in one flock and moved from paddock to paddock daily. That is to say, each field is grazed at the rate of about 130 head per acre for one day and then spelled for 13 days.

When lambing commences in July or August the daily moves continue, but only the unlambed ewes are shifted, the remainder being left behind in each field until there are sufficient to justify grouping in one flock and shifting each day. The idea is eventually to divide the ewes and lambs into two flocks of approximatey equal numbers and rotate each of these over seven paddocks. Consequently from about September onwards each field is grazed down once in seven days, that is to say, at the period of the year when the pasture is making the most rapid growth there is a shorter time between each grazing. Should the feed tend to get beyond the best stage one or more fields are shut up for hay and the flocks rotated in daily shifts over the remaining five or six paddocks.

On dairy farms the sward is allowed to become taller, and the practice is to graze off the top growth rather than the lower 2in. In the spring and early summer the growing periods may extend to almost three weeks, with longer spells over the remainder of the year. Naturally the milkers are first turned into the clean, fresh pastures and followed up by the young and dry stock. When these have been removed the roughage may be topped off with a mower and the field harrowed. However, this harrowing is carried out almost entirely with the object of spreading the droppings of animals and is never so severe as to pull out any of the pasture plants.

A high-producing pasture at Hastings. This field is stocked at the rate of two cattle and six sheep per acre, and had carried this number for four months. It could continue to hold this number for at least two more months but owing to wet conditions only light grazing was secured in the winter. All animals were in good condition with over half the cattle in prime order.

Again, on most sheep farms cattle are also kept to consume the rough coarse feed left by the sheep and maintain the herbage in the best possible condition for the production of nutritious fodder.

OTHER FODDER CROPS.

With improved pasture production following top-dressing, farmers are now conserving their surplus fodder as hay or ensilage, and the planting of supplementary fodder crops is not as popular as formerly. However, each season from 600,000 to 700,000 acres are planted mainly with turnips, rape, swedes and mangolds.

As a rule these crops are associated with the short-rotation pasture districts, and if the area is such that pasture stands tend to run out in say five or six years, a rotation is adopted which will bring each field under a fodder crop every five or six years, and by such means prepare the land for planting down to grass.

The most popular crops are turnips and rape, and large areas are to be seen in the Canterbury Plain, Hawke's Bay, Otago and Southland districts. They are mainly fed in winter, early spring and autumn. As a supplementary winter feed for cows several thousand acres of mangolds are also planted, the chief areas being Canterbury, Wellington, Taranaki and Auckand.

PASTURE ESTABLISHMENT ON PUMICE LAND.

Of recent years much has been done in the development of pumice land in the North Island. There are large areas of this class of country in the Auckland Province, extending towards the Bay of Plenty. It was generally regarded as being quite useless except for tree planting. However, the demonstrations that have been provided indicate that it is capable of producing really good pasture, provided that sufficient capital is available for the purpose.

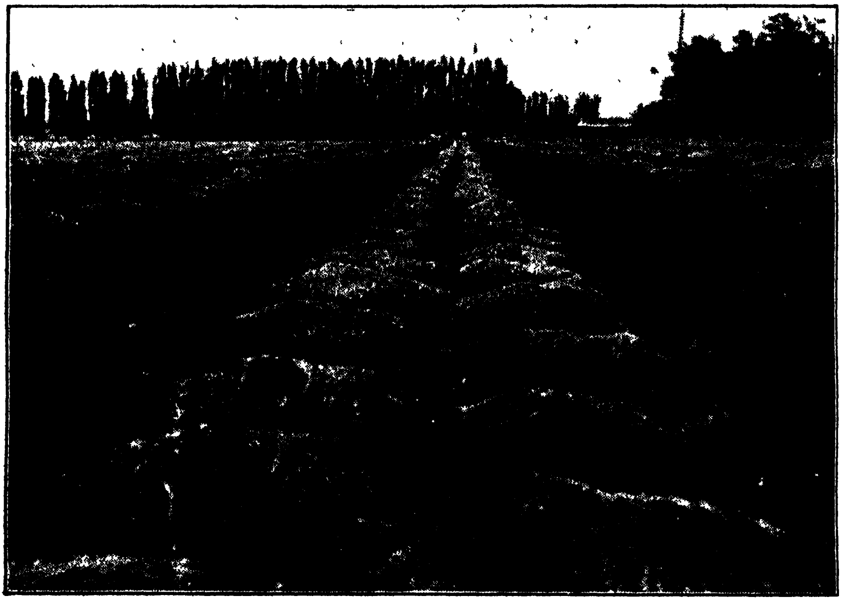
[From *The New Zealand Farmer.*]

Sheep grazing on a heavy crop of Swedes. This is one of the most popular of the supplementary crops for sheep.

Pumice itself is solidified volcanic froth containing mineral plant food, but because of its formation most of this is present in an unavailable form. However, by compaction and the incorporation of organic matter the pumice can be slowly decomposed, giving rise to a fair quality soil.

In its natural state pumice land is covered with a dense tangled mass of tea-tree, tussock, &c., which is first cut down and burned. After ploughing on a medium furrow the land is left in a relatively rough state to allow aeration and sweetening, and then some four or five months later packed down by heavy rolling. After shallow tillage it may be planted either with a temporary pasture consisting of Italian Rye Grass and Red Clover or with turnips, although sometimes a permanent pasture mixture is sown straight away.

The secret of success appears to be good compaction of the soil and adequate dressings of superphosphate. Applications of 6cwt. and sometimes 10cwt. to the acre in the year of establishment are necessary, followed by yearly top-dressings of at least 3cwt. per acre. The cost of bringing pumice land into production is therefore high, and figures from 12 dairy farms obtained by the New Zealand Department of Agriculture indicate that when all costs including buildings, fences, pastures, &c., are taken into account the expenditure lies between £16 and £19 per acre.



Perennial Rye Grass seed crop cut for threshing. Note the double row of cocks. Each cock can be lifted as a single forkful.

However, with proper management the carrying capacity rapidly rises to about half a milking cow per acre, and on the older farms to two-thirds of a cow or more.

Consequently the development of pumice land, which in its natural state is from an agricultural point of view most unattractive, has been proved an economic proposition and has opened the way for future agricultural expansion.

GRASS SEED IN NEW ZEALAND.

New Zealand has built up a large business in the harvesting and sale of grass seed, a trade which is likely to expand with the development of improved strains and the seed certification scheme now in operation. Approximately 100,000 acres of grasses and clovers are cut for seed each season, and of this area about 85 per cent. is situated in the Canterbury, Otago and Southland districts in the South Island, and most of the balance in the Hawke's Bay area in the North Island. The grain is harvested both by cutting and threshing, and also by stripping in the field. The latter method is associated with the lower rainfall districts, and on the Canterbury Plain it was interesting to see miles of fencing over which bags containing material from the strippers had been hung. The bags were only partly filled, making a layer some four to five inches thick, and by hanging in this way the grain, straw, &c., are able to dry right out before being cleaned. However, cleaning on the farm is relatively rough, and most grass and clover seed is machine dressed by merchants before being offered for sale. The chief seed crops are Perennial Rye Grass and Chewings Fescue, together with Red Clover, Cocksfoot, White Clover, Crested Dogstail and Brown Top, the most important of the others. Large quantities are exported to the United Kingdom, Australia, America and Canada, the first named country taking practically all the Crested Dogstail seed available after the local demand has been filled. The average yield of rye grass seed is from 17 to 20bush. per acre, White Clover, 120 to 150lbs.; Chewings Fescue, 200 to 250lbs.; Cocksfoot, 160 to 180lbs.; and Red Clover, 160 to 180lbs.

MANURES IN NEW ZEALAND.

A large amount of experimental work relative to the use of fertilisers has been carried out, athough there are still many problems awaiting solution. The outstanding result of these investigations has been the indication that phosphoric acid is the major limiting factor in crop growth and phosphatic fertilisers are easily the most important in the Dominion.

Deposits of phosphate rock occur but these are of relatively low grade, and as is the case with Australia, New Zealand obtains her supplies from the phosphate mines of Ocean and Nauru Islands.

Approximately 2,000,000 acres of pasture land are top-dressed annually, and the average application amounts to 2½cwt. per acre.

The quantities range from 1 to 2cwt. per acre applied once every second or third year, to 6 or 7cwt. per acre each year.

The mean dressing for the smaller dairy farms in the high producing districts is approximately 3cwt. per acre per annum, and for the larger dairy farms, about 2cwt. per acre per annum. The sheep farms receive less, whilst the applications are not so regular. Finally in the extreme fertile soils of the Hawke's Bay area many fields do not receive any fertiliser at all. March to May is the regular top-dressing period with lesser quantities applied in spring. As the result of very careful experimental work it has been shown that summer and autumn applications are better than winter or spring dressings, since when given at this time they appreciably improve production during the period of minimum growth, namely in the winter. Further, there is little advantage in applying two or three times during the course of the year as compared with once so far as total production of fodder is concerned. On the other hand, applications made just prior to periods of low production are definitely of advantage in spreading the pasture return. Moreover, late spring dressing increases the phosphate content of the herbage produced during the summer, and this may have an important bearing on the health of stock.

Lime is second to phosphate in quantity applied to the land. There has been a marked increase in the amount used in recent years, and in 1935 over 200,000 tons were utilised.

New Zealand has a number of easily accessible limestone deposits, the material of which is mainly of a soft nature, and can be ground to a powder at a reasonable price. As far as could be gathered the usual charge for ground carbonate of lime is from 11s. to 15s. per ton, whilst free railage up to a 100 miles distance is granted to *bona fide* farmers purchasing lime.

It is in the form of ground limestone that the lime is regularly used, and quicklime or slacked lime is very rarely availed of. However, it is surprising to find that lime is not sold under a guaranteed analysis, nor is there any standard for fineness of grinding.

Lime is more generally used in the North Island than in the South Island, but on the other hand a greater quantity is applied annually in the latter than the North Island. This means that the average dressing in the South Island is heavier but less frequent than that of the North, and applications of a ton or more per acre every four or five years are quite common, whereas in the North Island dressings of from 5 to 7cwt. per acre every other season are regularly adopted. Taking New Zealand as a whole, the mean application of lime per acre is 5½cwt. There has been no experimental work to test small and frequent applications with larger and more widely spaced dressings, but the general opinion appears to favour the addition of about 5cwt. per acre in alternate years. However, there has been much experimental work to show the response following liming; although the majority of such plots are simply field demonstrations, and no attempt to measure the increased pasture obtained has been made.

[From *The New Zealand Farmer.*]

Effect of carbonate of lime on pasture. Plot on the left was dressed with superphosphate only and that on the right with both superphosphate and carbonate of lime. The mean application of lime in New Zealand is 5½cwt. per acre and 200,000 tons are used annually.

An extensive programme of trials was conducted by the Department of Agriculture, and in many districts general improvement resulted, whilst in some areas the response in 75 per cent. of the experiments was classed as good to excellent.

Consequently, liming is a general practice, but this does not obviate the necessity of applying superphosphate, and the best results follow applications of both materials. This response to dressings of ground limestone impressed all members of the party, and as a result a series of demonstrational trials with local carbonate of lime has been planned for commencement this year in the higher rainfall and swamp areas of this State.

The work done with nitrogenous fertilisers has indicated that this class of manure is important in promoting the growth of out-of-season grass, but on the other hand, such increased growth is frequently followed by a slump in production. Since 1929 there has been a marked reduction in the quantity applied, and the tonnage imported to-day is only about one-third of that received six years ago. Generally speaking, nitrogen fertilisers are not regarded as being of economic value for the grasslands of New Zealand.

As a rule the soils of the Dominion are well supplied with potash, the exceptions being parts of the Taranaki and Southland districts. In these localities 1 to 2cwt. of muriate of potash is applied annually.

So far as the manuring of other crops is concerned, the usual dressing for supplementary fodders, such as turnips, swedes, rape, &c., is from 2 to 4cwt. of superphosphate per acre at seeding time. With the cereals approximately 1cwt. of superphosphate is added, the explanation for the relatively small quantity needed being, that such crops are generally favourably placed in the rotation.

For potatoes, 3cwt. of superphosphate and 1cwt. of sulphate of amonia is the regular manuring on the lighter land, increasing to 5 to 6cwt. of superphosphate and the same quantity of sulphate of amonia for the more fertile soils.

(*To be continued: the next instalment will deal with Dairying and Sheep.*)

TOBACCO GROWING.

PROGRESS REPORT ON INVESTIGATIONS, ETC., IN SOUTH AUSTRALIA.

[By R. E. Courthope Giles (Tobacco Instructor).]

The 1935-36 season has been a rather peculiar one for South Australia, for although the drought experienced has been exceptionally severe, crops are above the average in quality for the past few seasons, and because of a variety of reasons from which valued information has been obtained.

In the past, although early planting was always considered advisable to obtain the full benefit from the spring rains for plant growth with the dry summer months of January and February for ripening and harvesting the crops, the prevalence of Blue Mould rendered this almost impossible.

By the adoption of the Benzol method of raising seedlings, ample supplies of disease-free plants were available during October and November last to a number of progressive growers, who raised their requirements by this method under the supervision of the Department. Seedlings were also grown at Berri Experimental Orchard and at the Experimental Tobacco Farm at Penola in the South-Eastern district of the State. These frame-grown seedlings were ready for transplanting from six to eight weeks in perfect condition, and were very much earlier than would have been possible by the open-bed method.

Some 50,000lbs. of leaf have been cured, the major portion being grown by seven growers, all users of Benzol.

The majority of growers, who have used the open-bed method as in the past, have all suffered to a certain extent through Blue Mould, and owing to late planting and drought conditions have had very disappointing results, yields being very light and of poor quality.

Early plantings from Benzol beds have been entirely satisfactory, the quality being excellent.

NEW REGULATIONS UNDER THE TOBACCO INDUSTRY PROTECTION ACT, 1934.

The occupier of any land on which self-sown tobacco plants are or shall be growing, shall every year before the 31st day of July, completely destroy all tobacco plants by fire or burial.

It is now proposed at the suggestion of tobacco growers that the use of hydrocarbon vapours should be made compulsory in the raising of tobacco seedlings in order to eliminate as far as possible all avoidable sources of infection from Blue Mould.

Owing to the prevalence of wild tobaccos throughout the State, it would not be feasible to entirely eradicate the disease.

PESTS AND DISEASES.

Murray Irrigation Area.—Experimental plots of tobacco of 24 light varieties were established in various parts of the irrigation areas, between Renmark and Cobdogla, with the assistance of a number of landholders.

Tobacco Experiments at Waite Institute.

Dungowan Tobacco, grown at Macclesfield.

Adequate protection from the high winds was obtained by means of strips of sunflowers and maize, which were well established before transplanting took place.

A considerable amount of damage was done to crops during December and January last by insect pests, bud worm, stem borer, cut worm, and later by leaf miner. Keen growers overcame these difficulties by means of sprays and baiting, and succeeded in growing sound leaf.

Adelaide Hills and South-East.—These areas have been quite free from insect pests during the past season, Blue Mould being the chief trouble. Two cases of Frenching were found in the South-East, and a few isolated plants suffered from Mosaic. Dry conditions probably account for the small amount of damage done.

DISEASE RESISTANCE.

The Dungowan variety has as usual shown a certain amount of resistance to Blue Mould. However it is highly probable that Dungowan will lose its position as first favourite among growers owing to the success obtained this season with better-textured varieties, which prior to the discovery of the Benzol method it was almost impossible to grow in South Australia, but which with this treatment have done remarkably well this season.

SOILS.

The location of suitable tobacco soils is being steadily carried forward. Large areas are available for development in the South-East and Adelaide Hills areas, with rainfall of from 26in. to 32in. per annum. In the average season these rains are sufficient to ensure quick growth, providing that October planting is possible. Throughout the South-East water is readily obtainable from shallow bores or wells, and irrigation would not be a very costly matter. By next season several small irrigation systems will have been installed, more or less as an insurance against such a drought as at present obtaining.

Murray Area.—The success or failure of the experiments carried out in the Irrigation Areas has been decided entirely by the suitability or otherwise of the soils utilised.

Crops grown on the light Murray sand which is of an ashy nature have grown and cured well, and from a smoking point of view have highly desirable characteristics.

Yorke Peninsula.—Good land is to be found in the Stansbury Scrub Area, but development will be governed entirely by artificial water supply and the provision of adequate windbreaks.

The results obtained by an experimental plot are of a most encouraging nature, and certainly warrant further investigation.

Tintinara.—The foregoing remarks upon the Yorke Peninsula apply equally to this locality, but experiments here were not of a satisfactory nature, as transplanting was carried out too late in the season.

CULTURAL.

Every tobacco grower in the State is visited monthly by the Tobacco Instructor who assists with each phase of production from the seedbed until the leaf is finally marketed.

Varietal and fertiliser trials are conducted in collaboration with the growers.

The Departmental curing barns have been in operation in the Murray Area during the current season to assist new growers. Another barn is being erected in the Hope Forest Area for experimental work in the Adelaide Hills, while a tobacco experimental farm is being established near Penola in the South-East, properly equipped with barns, bulk store, and grading shed, where large-scale experiments can be carried out in the forthcoming season.

No encouragement is being given to old growers who have for various reasons ceased operations if their land is not considered entirely suitable for the production of the type of leaf which is at present in demand.

As the Benzol method of raising seedlings will undoubtedly facilitate and so encourage production, growers are being warned that improved quality will be necessary in future, as buyers will be in a position to pick and choose.

The incompetent grower will be forced either to improve his methods or finally cease production.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1935-36.

PART I.—AN OUTLINE OF WHEAT GROWING ATTAINMENTS AND THE CONSERVATION OF FODDER IN THE LIGHT OF PREVIOUS RESULTS FROM THE COLLEGE FARM.

[By Allan R. Callaghan, D.Phil,, B.Sc. (Oxon.), B.Sc.Agr. (Syd.), Principal,

INTRODUCTORY.

The college farm constitutes a complex unit, which, to the ordinary farmer, is difficult to describe; only by direct contact with the specialised work in hand can a true conception be formed of what is entailed. The farm is to the college, what the chemistry laboratory is to the chemist, or, more aptly perhaps, what the workshop is to the designer. It serves as a very essential background to student instruction, for, to the students, it affords a means whereby they may see, do, and follow classroom instruction in practice, be it with livestock, cropping operations or horticulture technique.

To those of us who have the responsibility of management and supervision it serves as a workshop which enables principles to be put to the test of actual practice, for the dual benefit of students and the farming community generally. It also serves the very important function of field experimentation, and upon such, progress in agriculture and livestock husbandry is wholly dependent. Whatever the theory disclosed or hypothesised by the scientific research officer, if it is to serve the man on the land, it must have utilitarian significance; to assess this significance it must first be applied under farm conditions.

The college farm has, therefore, the twofold object of demonstration and experimentation; the relative development of both represents the outward expression of the thought of the institution. In turn, the results obtained are a measure of the worth of the initial thought and its practical application. Having applied precepts successfully, they are no longer such, for they become absorbed in the general everyday knowledge of agricultural practice. In this respect it is impossible to conduct the diverse activities of a large mixed farm one season after another on a progressive and active basis, without realising what a multitude of problems remains unsolved, even unexplored, and from the experiences of every season new ideas crowd one upon the other necessitating a sorting out, followed by the application of some.

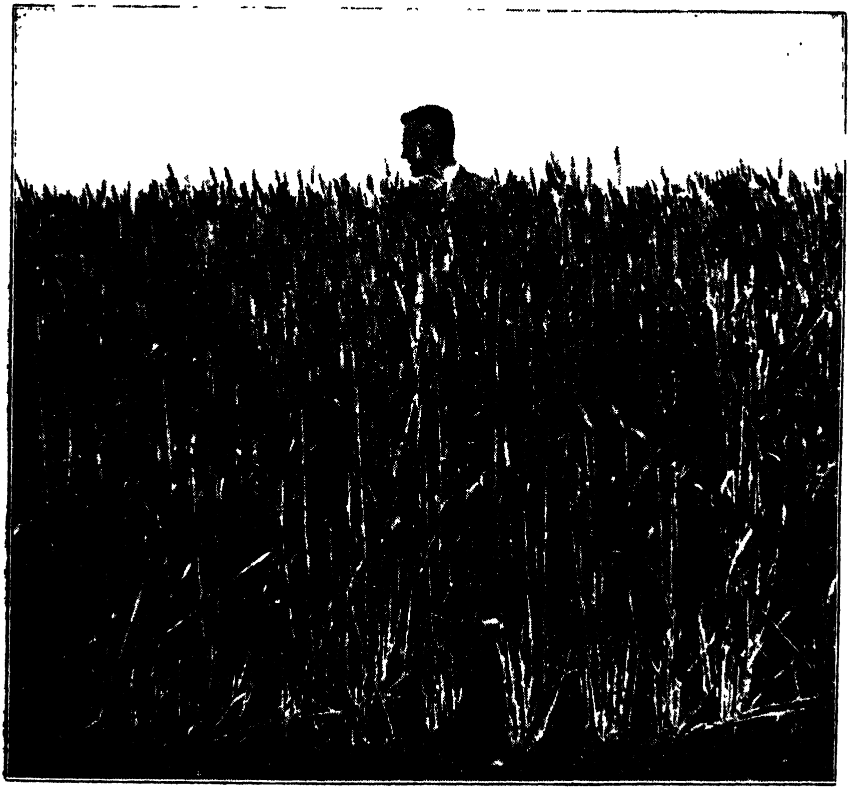
The college has now had over fifty years of experience along these lines; during that time vast strides have been taken in the progress of agriculture. To that progress, especially as it applies to this State, the college has contributed well. The influence of college work has been very diverse, and there are few avenues of farming which have not come within the orbit of its investigation. As contributions to the general welfare of the farmer, just claim can be made by the college to such phases as the development of dry farming methods and the use of superphosphate in the early days, the breeding and selection of cereal varieties, especially wheat, suitable to the environment of our own particular wheat areas, the growth of vines and proper pruning methods; the development of rotational systems to meet the agricultural development from the mere pioneering stage to the stage of balanced diversified farming, and in this latter connection, the sponsoring of the fat lamb industry as an integral part of that system, coupled with the application and advocacy of a proper system of fodder conservation. Incidental to such major developments, details of practical knowledge have accrued and general procedure with cropping and livestock activities has become increasingly efficient.

My intention, therefore, at the outset of this year's report is to incorporate some of the data of previous years, partly to demonstrate the progress made, partly to afford significant relief to the excellent results obtained on the farm during the last three years, and especially 1935, and partly to summate the results for future reference and guidance.

Unfortunately, college records are far from complete. The most that are available record cereal cropping results since 1904. These form a useful guide and setting for the results obtained in recent years, and cover the most important aspects of college field work. Latterly, livestock have become so important a part of our agriculture that a gauge to progress has become more essential and for the last three years regular figures of livestock carried have been featured in these annual reviews. As an index to the policy of earlier years, however, fodder conservation can be taken into account, and in this respect comparative data are available.

WHEAT GROWING RESULTS.

From the beginning, wheat has been the main crop grown on the college farm. Except for an occasional season or two no results of any consequence are available for the twenty years prior to 1904. This is most unfortunate, for during those years of initial experience dry farming methods were being developed and the full use of superphosphate as a fertiliser was being appreciated. These two developments, based on the seasonal experiences of those early days, must have had very telling influences on the yields obtained.



Favourable conditions during the growing period of the crop in 1935 meant that thick stands of Wheat finished well, to give high yields of plump grain.

The records from 1904 onwards are complete, thanks largely to the systematic efforts of Professor Perkins, who took charge of the college in that year. For the most part the fluctuations in the figures find explanations in reports published from year to year, but as time progresses the major experiences of past seasons become absorbed in the general knowledge of wheat growing, and eventually the year's results enter the college records as nothing more than a line of figures in a table of statistics. It is wise, therefore, that detailed accounts should be made available each year to explain how each season's results are achieved. By this means they are held, for a time at least, from the uninteresting climax aforementioned.

It must be admitted, however, that the accounts do lose much of their immediate application as the years pass, but certain aspects are always of significance when comparisons are sought. In this respect the relationship between wheat yields and the seasonal rainfall obtained acts as a guide to the growth in the efficiency of farming methods; this is especially applicable on one farm where seasonal comparisons are desired. It is not, by any means, infallible, but it is a more useful and reliable indication of most season's results than the actual bushel yield itself. Of this an excellent example is afforded in the college yields for 1914. The actual yield per acre in this year was very low at 11bush. 28lbs. but this yield was high in proportion to the amount of rainfall received during the growing period of the crop (only 4.85in.), giving a figure of 2bush. 21lbs. per inch of seasonal rainfall. Similarly, in 1929, although the actual yield was only 15bush. 11lbs., the yield per inch of seasonal rainfall was good at 1bush. 51lbs.

This review is largely based on this relationship between rainfall and yield; for this reason some amplification is advisable. The college farm, like the whole of the main wheat areas of Australia, is dependent upon winter rainfall and the growing period of crops is from April to October inclusive. The State Statist computes the so-called "Useful Rain" of his statistical reports, from the period April-November inclusive, but November, under the conditions prevailing at Roseworthy, cannot be regarded as part of the growing period of the wheat crop, for by the end of October all growth has ceased and November rains are more of a hindrance than a help. The April-November figure, however, is probably fair and logical for late districts, but for the sake of general and specific comparisons with college data, the April-October figures have been compiled and are used herein.

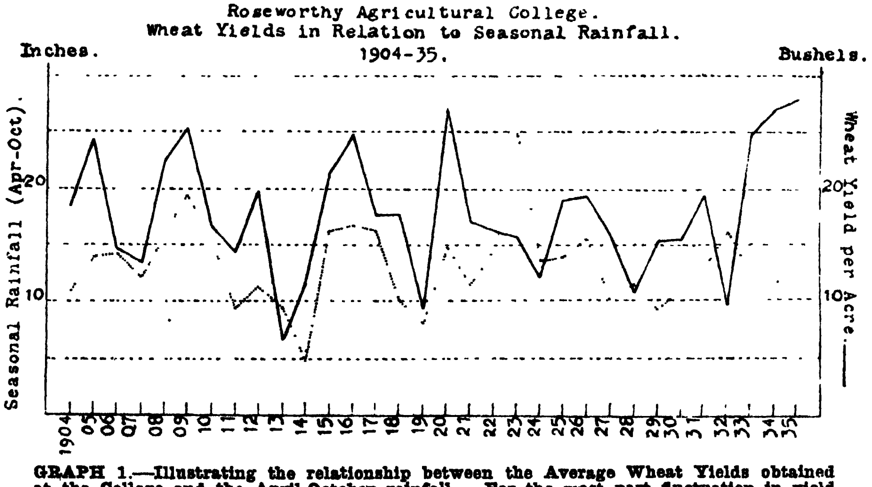
Mean annual rainfall, 17.47in.
Mean wheat yield for 32 seasons, 17bush. 46lbs.

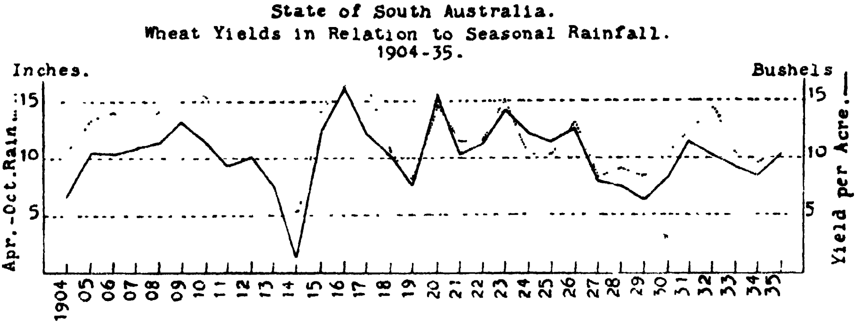
Certainly some incongruous results do appear, but this is only to be expected where a fairly long period is under review for there are other factors which do militate against good results. A rust epidemic may be particularly virulent or storm damage severe in a year of high rainfall, with the result that low yields may be recorded. From Graph I. the 1923 figures seem to be the most inconsistent of all, but here again untoward circumstances impaired the season's results. In that year continuous winter rain delayed and complicated seeding; the seed was eventually sown in a seed-bed heavily laden with moisture and, indeed, only half the seeding programme was ever finished.



GRAPH 1.—Illustrating the relationship between the Average Wheat Yields obtained at the College and the April-October rainfall. For the most part fluctuation in yield corresponds closely with the variation in seasonal rainfall. Generally speaking, the further the yield curve lies above the rainfall curve the more thrifty the crop growth, and, by inference, the more efficient the farming.

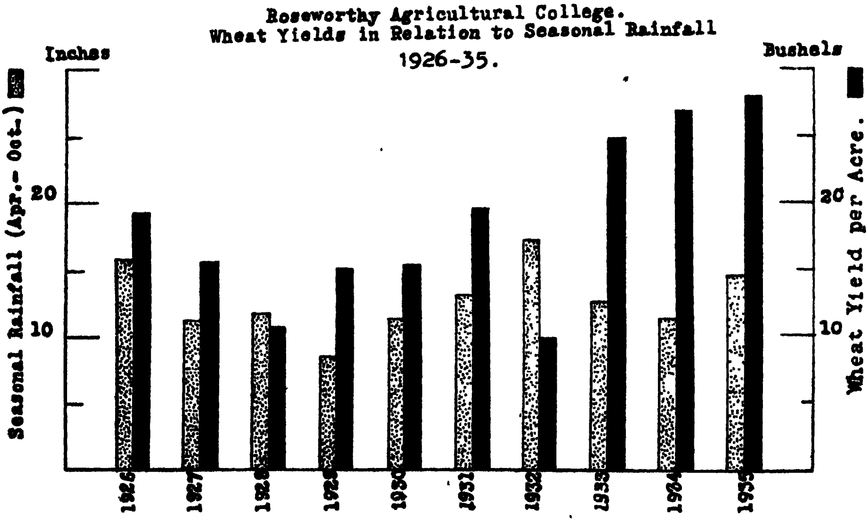
For the sake of contrast, and from the point of view of general interest, I have graphed the State average yields, and April-October rainfall, on the same scale as the college farm results. While it is not inferred that the comparison is a fair one, the parallel nature of the two sets of curves is an indication of how far seasonal fluctuations controlled college, as well as State, average yields.

Besides natural phenomena the story of college farming has also been affected by accidental factors which one can only class in the category of human agencies. The poor results of the season 1932 can be wholly attributed to this cause. At the time when soil preparation should have received careful attention college affairs were in the melting pot, student labour was unavailable for the working of fallows, and later, when matters of administration and policy were settled, heavy rains made seeding difficult and well-nigh impossible.



GRAPH II.—Depicting the Average Wheat Yield for the State of South Australia in relation to the April-October rainfall. In this case the yield line lies below the rainfall curve, but both follow the same general trend as those in Graph I.

It must be conceded, therefore, that in some years the accidental factor has had an adverse effect upon yields, and presented fluctuations in the records which cannot be explained on a general basis. The last three seasons, 1933, 1934, and 1935, have been fairly free of the accidental circumstances mentioned above, except that some losses were occasioned by rust in 1933, and by hail damage in 1935. All three seasons have been especially notewothy, and, as the graphs indicate, as far as wheat yield is concerned they are outstanding years in the college records.



GRAPH III.—Portraying, in graphic form, the Average College Yields (black) over the last decade in relation to the seasonal rainfall (dotted). Note the exceptionally good results obtained in the last three years.

The analysis of the data of past years, together with those of the last three seasons, reveals the following highly satisfactory conclusions, all of which indicate that college farming has progressed on sound and unimpeachable lines. These results are substantially illustrated in Graph I. and III.

Firstly, *no three successive seasons have given such consistently high returns. The average for the three years was 26bush. 36lbs., which is 9bush. 44lbs. above the mean yield of the previous 29 years.* The mean yield has been raised in the three years from 16bush. 52lbs. in 1929 to 17bush. 46lbs., or, in other words, by 54lbs.

Secondly, *in 1933 the bushel yield of wheat obtained per inch of seasonal rainfall was better than that obtained in any previous year, with one exception. The actual yield per acre was 24bush. 51lbs., and the seasonal rainfall 12.61in., so that 1bush. 58lbs. per inch of seasonal rainfall was obtained.* This figure was only once before exceeded, and that was in the abnormal year of 1914, when a yield of 11bush. 28lbs. was obtained on a seasonal rainfall of only 4.85in.

Thirdly, *in 1934 the actual yield per acre of 26bush. 57lbs. equalled the college record set up in 1920, on a seasonal rainfall of only 11.33in., so that the yield of 2bush. 22lbs. per inch of seasonal rainfall was a definite improvement on the previous year's figure of 1bush. 58lbs., and eclipsed the former record of 2bush. 21lbs. set up in 1914.*

Fourthly, *in 1935 a yield of 27bush. 59lbs. per acre was obtained, thus exceeding the previous actual highest yield by over 1bush. per acre.* The rainfall of 14.67in. for the period April-October was higher than in the two previous years, and the yield per inch of seasonal rainfall was slightly lower at 1bush. 55lbs., but even so was better than any year prior to 1933, except 1914. It is only fair to mention that these 1935 figures would have been much better had it not been for serious hail damage over an area of about 80 acres of crop.

ROSEWORTHY AGRICULTURAL COLLEGE.

Mean Wheat Yields, 1925-35, *Showing the Rapid Recovery in the Mean Yield in the Last Three Years.*

No. of Seasons.	Year.	Mean. Bush.	Mean. Lbs.
22	1925	17	25
23	1926	17	30
24	1927	17	26
25	1928	17	10
26	1929	17	5
27	1930	17	1
28	1931	17	7
29	1932	16	52
30	1933	17	8
31	1934	17	27
32	1935	17	46

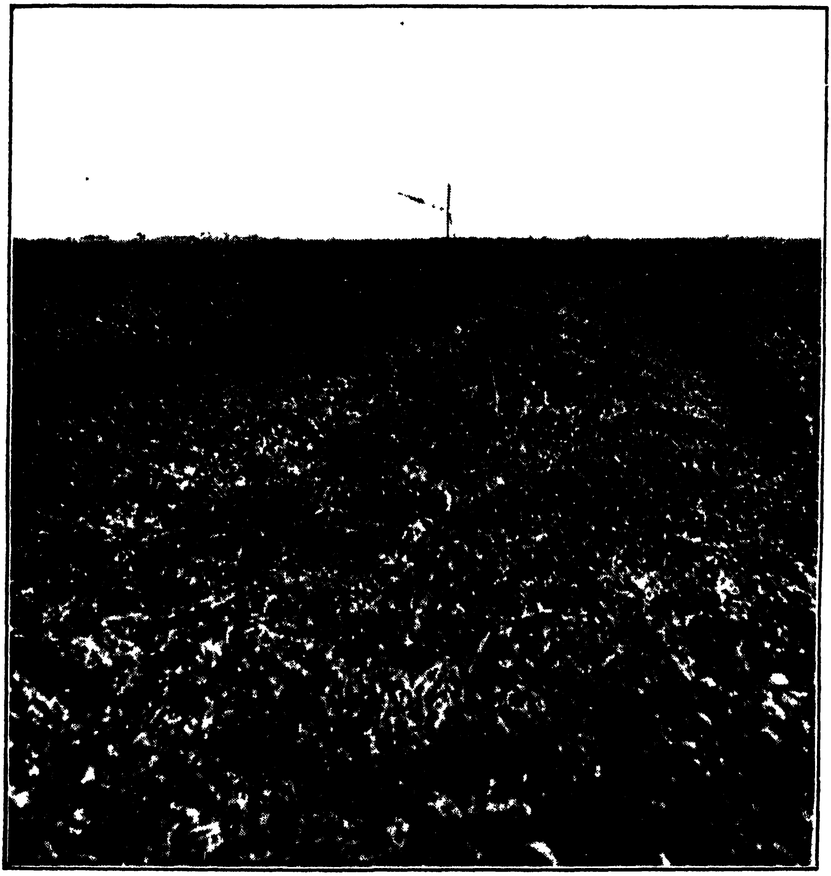
The hailstorm above referred to came as a very severe blow to our hopes in August when it swept, with great severity, across a magnificent crop of Sword, which had just begun vigorous upward growth. The crop was, to all intents and purposes, ruined, but being the only quantity of pure seed Sword on the farm it had to be left in its chaotic condition to make the best recovery it could. Omitting this hail damaged crop, with its low yield of 14bush. per acre, from the year's figures the average yield over the remaining areas was 30bush. 44lbs. Further, had the crop been unmolested and yielded as well as its early promise, the average yield undoubtedly would have been in the vicinity of 32bush. per acre. Such are the disappointments of farming!

LIVESTOCK AND THE CONSERVATION OF FODDER.

Wheat growing has been, and still is, the main undertaking of the college farm, but for many years livestock have played an important role. The importance of livestock in the development of a fully balanced agricultural system has called for, and has rightly received especial attention of late; in this respect the college has taken a strong lead and has emphasised repeatedly both the economic and agricultural advantages of combining stock raising with arable farming. The advocacy of such methods has been based on sound practical example and not on

An incredulous visitor knee-deep, and over, in Burr Medic and other volunteer growth (Fletts A). 1935 was an especially good fodder year; good rainfall, plus residual phosphate, sponsored a luxuriant growth on ley land, large quantities of which were ensiled.

any hypothetical or untried theory. The college farm at present is carrying the equivalent almost of one sheep to the acre in addition to 50 working horses, which are allowed for normal farm operations. This is a striking testimony to sound agricultural practice based on permanent methods, especially when it is considered that, of the total area of available land of just about 2,000 acres, between 500 and 600 acres are fallowed annually and about 800 acres are cropped, leaving only about 600 to 700 acres of pasture or ley land. For the last three years definite figures of all livestock carried have been translated into sheep per acre on the basis that all cattle, including cows in full milk and young animals, are the equivalent, on the average, of five sheep, and that each horse over and above the 50 allowed for the normal working of the property is equivalent to eight sheep. Those competent to judge will admit that these equivalents are on



A general view of Fletts A. after the mower had opened out for silage harvest on the 21st August, 1935. A veritable mat of Burr Medic was associated with self-sown Wheat and other volunteer growth. From 55 acres, 310 tons of green fodder were stacked as silage.

the conservative side and might well be slightly increased. In this way the livestock carrying capacity of the farm is assessed. Whether the final result is strictly accurate or not does not concern me, for the main consideration is to obtain annually comparable figures whereby a true reflection of each season's livestock activities will be obtained; ultimately, when a period of years is considered, a true index to the continuity of the carrying capacity will be possible.

The only means of assuring the continuity of carrying capacity in an environment such as Roseworthy, and South Australia in general, is to make adequate provision for the supply of feed during the periods of shortage which occur regularly every summer and autumn, and during the periods of shortage due to prolonged dry periods. It is definitely a case of making full, systematic, and adequate use of the years which provide a superabundance of feed; in these years it is fundamentally wrong to increase the stock on the property just because there is an abundance of feed. Continuity of returns from animal produce is a very significant consideration, for more often than not, the best markets are those which occur in times of feed shortage. The farmer able to meet the market regularly, and especially in time of such shortage, invariably reaps substantial benefit. To do this the only wise procedure is to settle down to a regular carrying capacity, feed reserve fodder when it is necessary, and take full advantage of the good seasons, not by the temporary palliative of increased stocking, but by the dependable system of conserving as much fodder as there is to spare.

The figures of the carrying capacity of the college farm for 1934 and 1935 given below represent a level which, it is hoped, will not fluctuate significantly year in and year out. To demonstrate this successfully a number of years is necessary, but indications are that the level is not too high.

ROSEWORTHY AGRICULTURAL COLLEGE.

Treatment of Farm Areas in Relation to the Livestock Carrying Capacity.

1933-35.

	1933. Acres.	1934. Acres.	1935. Acres.
Area fallowed	545	604	525
Area cropped	799	797	1,001
Area pasture, or ley land	635	578	453
Total area	1,979	1,979	1,979
Mean number of sheep	939	1,096	1,047
Mean number of cattle (including young stock)	99	90	91
Mean number of horses (including young stock)	78	92	91
Equivalent in sheep (after allowing for 50 working horses for farm operations)	1,703	1882	1,830
Sheep per acre	0.86	0.96	0.93

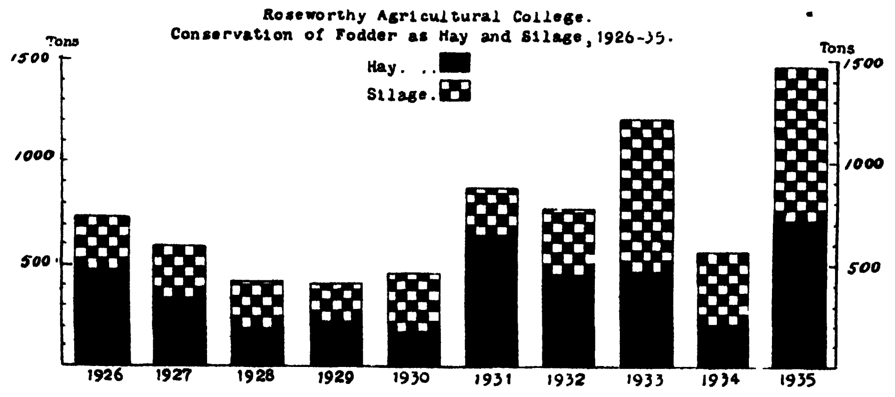
The last three seasons have given a wide variation, and while in 1933 large reserves were possible because of a particularly good feed year, 1934 was a year of feed shortage due to an excessively dry period in May, June, and July. So that for the year 1934 only normal yearly supplies of fodder could be gathered. Last year, again, fodder was particularly abundant, and every effort was made to put the reserve in a sound position. To this end 720 tons of hay and 749 tons of greenfeed as silage were conserved, making a total of 1,469 tons of roughage handled.

ROSEWORTHY AGRICULTURAL COLLEGE.

Conservation of Fodder as Hay and Silage for the Decade 1926-35.

Season.	Hay Made. Tons.	Silage Made. Tons.	Total Roughage Conserved. Tons.
1926	471	264	735
1927	336	261	597
1928	196	220	416
1929	222	189	411
1930	178	286	464
1931	653	219	872
1932	467	305	772
1933	480	730	1,210
1934	207	356	563
1935	720	749	1,469

The accompanying figures, which are the basis for Graph IV., record the fodder reserves gathered over the last decade. The policy for increasing work with livestock is evident from the figures given for the last three years. Both 1933 and 1935 represent two big harvest years from the point of view of fodder conservation, and at the end of the 1935 season there were sufficient reserves on hand to maintain the college livestock carrying capacity on an even keel until October, 1938, provided average, or even a little below average, conditions prevail.



GRAPH IV.—The conservation of roughage as Hay and Silage at the College over the last decade is illustrated herein. Note the general increase in fodder conserved and especially the substantial tonnages made in the good fodder years of 1933 and 1935.

I have endeavoured in this outline to portray the success and development in two of the most important general undertakings of the college farm, and, in doing so, I have shown the results of 1935 and the two previous seasons in the full perspective of results obtained in previous years. The difficulty in handling recorded data extending over long periods is to make the matter interesting; I offer this as an excuse for not elaborating more fully on specific results, and for not burdening the text with results of lesser significance. The general aim has been to introduce the results obtained on the farm in 1935, details of which will be given in subsequent articles. A general word picture of standards previously attained lends colour to the year's work in which a record wheat yield was obtained, and more produce was gathered from the farm in the form of grain, hay, and silage than any other year in the history of the college. The season was favourable, with rainfall slightly above average; in other words, growth conditions for crops and fodder were better than usual. The fact of greatest practical importance, however, is that full advantage of the favourable season was taken, the management of the farm being directed to this end.

THE REMOVAL OF SEEPAGE WATERS BY PLANT GROWTH.

[By F. R. ARNDT, Horticultural Instructor, Upper Murray Irrigation Areas.]

(A paper read at the Conference of River Murray Branches of the Agricultural Bureau, held at Renmark, 18th June, 1936.)

In a paper on Irrigation and Drainage read by the writer at the last Conference of the River Murray Branches of the Agricultural Bureau, held at Moorook last June, mention was made of the beneficial results that have often been obtained by the growing of moisture-loving plants for the removal of surplus soil water from irrigated lands. In the present paper it is intended to elaborate upon this subject, and to show how plant growth may in many ways be utilised to help to combat the seepage menace.

In the first place it must be realised that in places where the seepage problem has obtained formidable dimensions and large volumes of free water have accumulated, conditions may often be impossible for the growing of plants of any kind, and in such cases only drainage can be effective.

Vineyard destroyed by heavy concentration of salt.

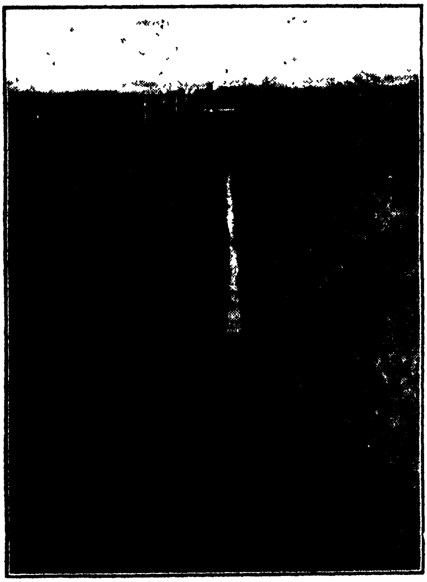
Notable instances of such large accumulations of free water can be found in regard to the two artificial lakes that have been formed by drainage waters in the Berri and Barmera areas, while at a number of other places the land has been allowed to become so badly waterlogged—with the consequent accumulation of injurious salts in the surface layers of the soil—that plants will not grow thereon. In such cases it is apparent that only drainage or pumping will be effective in removing the vast accumulation of seepage waters that has taken place.

As, however, badly affected seepage areas of any great extent are usually due to the accumulation of the combined drainage waters from a number of holdings, something may often be done to lessen the volume of underground waters at their source, so as to ease the seepage problem of the affected areas, and it is here that the growing of moisture-loving plants may be of considerable help.

THE TASK OF THE INDIVIDUAL IRRIGATIONIST.

The first care of every irrigationist should be, of course, the efficient use of his irrigation water. Good irrigation practice demands that every plant should as nearly as possible receive the same amount of water and that there should be no overwatering of the land.

Experience reveals the fact that such is usually not the case, even where care is exercised in watering, because the imperfections inherent in the furrow system of irrigation, by which means most orchards and vineyards are watered, makes an even watering practically impossible. The excess water received at the beginning of the irrigation runs (which portion of the plantation receives the most water) soaking down deeply into the subsoil is a prolific cause of seepage. However, seepage troubles and a general rise in the watertable can also be brought about by the flooding system of watering if an excessive amount of water is applied to the land.



Drain for the removal of seepage waters in course of construction.

The irrigationist has to be ever vigilant in regard to the watering of his land and do all in his power to avoid the bringing on of seepage. Should he find that this is developing on his holding, then he must lose no time in combating it before the menace becomes serious.

THE REMOVAL OF SURPLUS WATER BY PLANT GROWTH.

That plants of all kinds remove a considerable amount of moisture from the soil by means of transpiration through their foliage has been known for a long time, but it is only within comparatively recent years that attempts have been made to make use of the growing of plants for the drying out of seepage lands. Plants that may be grown for this purpose consist of various kinds of trees, shrubs, grasses, and other plant varieties. Fodder plants such as lucerne, Japanese millet, Sudan grass, and barley have been the ones chiefly used, but larger plants may also be of value in many cases.

TREES AND SHRUBS AS DEWATERING AGENCIES.

At some of the irrigation settlements trees of various kinds have been planted along the banks of the earth channels to absorb the surplus moisture seeping through them, and often these have been of considerable help in minimising the seepage troubles arising from that source. The trees that have been chiefly grown for this purpose consist of gums, willows, poplars, tamarisks, and palms of various kinds.

Of these, the willow is the most moisture loving, as it will grow with its roots in water, but being deciduous is effective in transpiring moisture only during the summer months.

Date Palms growing on salt impregnated land.

Palms of most kinds are also great lovers of water, and some are highly tolerant to saline conditions as well. Of these, the Date palm (*Phoenix dactylifera*) is probably one of the most salt resistant plants in Nature, as it will grow in situations where, owing to the salinity of the soil, most other plants fail to live. That the Date palm requires for its best development copious supplies of water, as well as a considerable amount of salt in the soil, has long been recognised, and in this connection it is interesting to note that the ancient Greek historian (Herodotus), in describing the conditions existing in the irrigated lands of Babylonia at his time (about 400 B.C.), says that the chief plant varieties grown in that country consisted of Date palms and barley—two highly salt-resistant plants—indicating that the irrigationists of those days probably had their salt troubles also and found that these plants suited their conditions best.

Other plants that have at times been used as dewatering agencies are Pampas grass and bamboos, which have the capacity of growing in wet situations and transpiring large quantities of water.

REMOVAL OF SURPLUS SOIL MOISTURE BY FODDERS.

As previously mentioned, fodder plants have been the ones chiefly used to absorb the surplus moisture from seepage lands. The growing of these plants serves a double purpose, as not only are they of value in drying out the soil, but they serve as stock food as well.

The variety chiefly grown here has been lucerne, which, on account of its deep rooting system and its great capacity to absorb large quantities of water, has been very valuable in this respect. Other varieties used to a lesser extent include barley on account of its great salt resistance, and such summer-growing fodders as Japanese millet, Sudan grass, and maize.

VALUE OF LUCERNE.

As just stated, lucerne has proved to be the most valuable of the fodders as a dewatering plant. There are, however, situations in which it will not thrive, such as on lands where free water is close to the surface of the ground (which should be drained) or where the surface layers of the soil are highly impregnated with salt, where barley should be tried as a first crop. On other moist situations, where it has been well planted and looked after, lucerne has given highly beneficial results in the drying out of the land.

Lucerne growing among young Orange trees.

During the past three or four years the writer has been advising growers who have fruit trees or vines suffering from excessive soil moisture to interplant with strips of lucerne, and young and mature citrus trees, fig trees, and various kinds of vines have been so treated. The results have been generally satisfactory, and in one instance a watertable existing on land planted with fig and orange trees was in two years reduced from 2ft. 6in. to about 6ft., and the trees were greatly improved in health thereby.

A remarkable instance of deep rooting and water absorbing capacity of lucerne came under the writer's notice some time ago. It was related in the paper upon this subject at last year's Conference, but is worth repeating here. This was to the effect that a leading Berri fruitgrower, who had put down a tile drain, which was working well, removed a row of weak trees situated parallel to and above it, and in its place planted a 12ft. strip of lucerne. The result was that although the lucerne was not planted near enough for its roots to enter the drainage pipes, yet after it was established the drain stopped running, showing that the rooting system of the lucerne intercepted and absorbed the water as this drained down the slope along the subsoil.

LUCERNE IN PLACE OF TILE DRAINS.

From the foregoing examples it is apparent that the growing of strips of lucerne may in many places be as effective in lowering the watertable of seepage lands as a system of tile drains. Moreover, in planting lucerne not nearly so much expense is incurred as in putting down tile drains, and, in addition, a valuable fodder is secured.

THE DRAINAGE OF HEAVY SOILS.

On certain soil types of a firm nature, such as exist on portions of the river flat lands of the Renmark and Block E districts, and to a lesser extent on the Berri and Cobdogla Irrigation Areas, drainage is naturally much slower than on soils of a more porous nature. Hence, where waterlogging of the subsoil has taken place on such lands, for tile drains to be effective they have to be closer to each other than would be the case where the soil was looser in texture. If tile drains gave satisfactory drainage on sandy land at, say, 2 chains apart, then on heavier land to give the same results they may have to be half that distance from each other, or even less. The writer has known a tile drain situated in heavy clay soil that was draining the water for only 12ft. on either side of it.

Owing to its great cost effective tile drainage on soils of this nature often may not be an economic proposition, and it is here where the growing of lucerne may be of the greatest value. The lucerne can be grown in strips along the rows of fruit trees and vines, and on land where the previous plant occupants have failed. Once it is established the lucerne should be watered very sparingly, so as to force it to utilise as much of the surplus soil moisture as possible, and thereby lower the watertable.

DRAINAGE OF LOW-LYING LANDS.

Another class of land on which seepage troubles are difficult to combat is that which is situated in low-lying valleys or depressions, from which it is at times exceedingly difficult to remove the accumulated drainage waters, even if the land is drained. In such situations wells are usually put down until a layer of drift sand is reached, and the drains are led into these.

Where this underground layer of sand is of very large dimensions, or leads directly into the river valley, the drainage waters can be successfully removed, but often the wells lead only into comparatively small sand deposits, which in time either fill with water and so are rendered useless for drainage purposes, or drain so slowly that after an irrigation they temporarily fill up, and for a time cause the drainage pipes to remain filled with water, to the detriment of the plants growing near them.

In such cases, also, the growing of strips of lucerne along the fruit tree and vine rows, or in other situations, will give beneficial results, as the lucerne, by transpiration through its foliage, will remove much of the surplus moisture from the soil and so prevent undue concentration at any one place.

WINTER COVER CROPS.

On a large number of irrigated holdings the growing of winter cover crops. chiefly of a leguminous nature for green manure, is now an annual practice. Besides adding to the fertility of the land, such plants will absorb a considerable quantity of soil moisture and so help to dry out moist land if this is not overwatered.

There has, however, been a tendency among a large number of growers to apply large quantities of water to their cover crops in order to promote a good stand of herbage to plough under in early spring, with the result that in many cases more water has been applied than the plants can absorb. Unless the drainage of the land is very good, this surplus water will lead to the waterlogging of the subsoil on level land, or where the country is undulating will soak along the subsoil from the higher to the lower areas and bring about seepage there.

It is a dangerous practice to apply heavy and frequent irrigations to cover crops, and in a normal season one good autumn watering should be sufficient to give the plants a good start, leaving the winter rains to carry them on. The application of as many as three special irrigations in a season for the growing of cover crops, as has at times been practised, is certainly a mistake, and if persisted in can only lead to drainage trouble.

Cover Crop growing in between vine rows.

It is the writer's opinion that many of the seepage troubles that have arisen within recent years have either been brought on, or accentuated, by the too heavy watering of cover crops, and lighter waterings of these crops must be practised in the future if the seepage menace is to be kept in check.

CONTROL OF SOIL MOISTURE BY PLANT GROWTH.

For the best results to be obtained from the growing of plants for the reduction of the surplus moisture in the soil, it is necessary that the work should be carried out in a systematic manner, the writer believes that beneficial results would follow if some such procedure as the following was adopted by irrigationists:—

(1) In moist situations in orchards and vineyards, where the soil is not too saline for lucerne to grow, strips of this plant should be planted along the fruit tree and vine rows. These strips should be from 4ft. to 6ft. wide among vine rows and about double that width in between fruit tree rows where there is sufficient room. For bad cases of seepage lucerne should be planted in every row, but where the trouble is less serious the planting of every other row should be sufficient.

(2) The lucerne should be regularly watered until it is established, after which, unless suffering from drought, but little water should be directly applied to it, so that the plants are compelled to absorb as much of the surplus soil moisture as possible. The lucerne should be encouraged to make good growth by regular cutting and by an annual application of 2cwts. to 3cwts. of superphosphate per acre, as the more it can be induced to grow the more moisture will it remove from the soil.

(3) As has been previously stated, where the land is too saline to grow lucerne, barley as a winter and Japanese millet as a summer crop should be tried. As these fodders absorb considerable quantities of salt, the growth should be cut and carted off the land and fed elsewhere, so that the amount of salt in the soil may be reduced thereby. After several years of this treatment sufficient salt may have been removed from the soil to enable the land to grow lucerne successfully.

(4) In watering trees and vines interplanted with lucerne or other fodders, the water should be applied close to the fruit varieties so that the salt in the soil may be leached downwards and sideways away from them. As the lucerne, in drying out the land, may leave a concentration of salt in the surface layers of the soil, it may at times be necessary to give the fruit trees and vines, and even the lucerne, comparatively heavy surface waterings to leach the salt down into the subsoil beyond their root systems.

(5) On lands which show a tendency to develop seepage it is also a good practice to plant the headlands and footlands with lucerne to help to keep down the watertable. This is especially desirable where there are double headlands, due to channels running through the middle of the holding and where large quantities of water are consequently absorbed by the land. The spreading of the lucerne around fruit trees and under vine trellis can be prevented if good tillage operations are practised.

(6) Very often it may not be sufficient to plant only the moist places with lucerne, as the surplus soil moisture often comes from higher levels, and is at times so copious as to prevent any satisfactory plant growth in low-lying areas. In such cases if one or more strips of lucerne are planted higher up the slope where no seepage is apparent, the surplus soil moisture in soaking along the subsoil is intercepted by the deeply growing lucerne roots, and so is dissipated into the atmosphere through the plant foliage.

To have a plot of sufficient size for this purpose sometimes it may be necessary to remove a row of fruit trees or vines. This, however, will not result in loss if the seepage trouble is conquered. Practically all irrigationists grow lucerne for stock food, and it is best to have this growing where it will do drainage work as well.

Although in the reclamation of seepage lands tile drainage has, and will, continue to play an important part, especially where large accumulations of drainage waters have taken place, the growing of moisture-loving plants, especially lucerne, if judically used, is of the greatest help in overcoming the seepage menace.

The chief advantage of the growing of plants for this purpose lies in the fact that by their absorption of the surplus water as this moves along the subsoil, the excessive accumulations of drainage waters are prevented from taking place in situations that would otherwise be liable to seepage, and so make the laying down of costly tile drainage systems unnecessary.

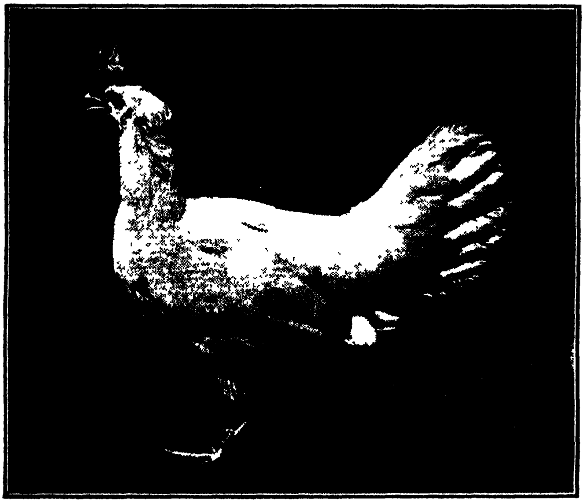
It is therefore reasonable to suppose that if the irrigationists of the Murray Valley were to take up the planting of the deeply rooting lucerne plant in a systematic manner, the seepage menace would in many cases either be checked or entirely overcome, and the development of serious drainage troubles in the future would be prevented.

PARAFIELD EGG-LAYING COMPETITION, 1935-36.

[A general review of the Competition by C. F. ANDERSON (Government Poultry Expert).]

The Third Egg-laying Competition in which the weighing of each egg throughout the currency of the test was practised terminated at Parafield on the 31st March, 1936. As in all Egg-laying Competitions conducted at Parafield Poultry Station, the test covered the full period of the year commencing on the 1st April, and terminated on the 31st March following.

As the results of this method of egg weighing are more closely studied it is realised that the system adopted at Parafield Poultry Station constitutes the only method of making a definite and accurate record of the weighing of eggs. The maintenance of egg size is especially important in a State like South Australia, where a very big proportion of the production has to be marketed overseas during certain months of the year and interstate during other portions of the year.



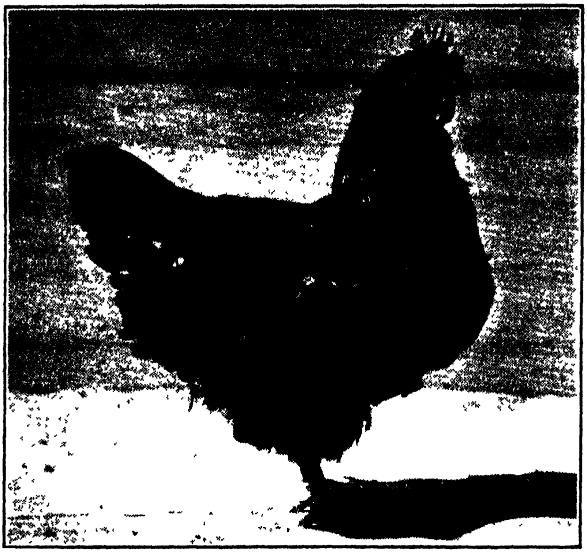
Highest Score in Competition—247 first-grade Eggs. White Leghorn Pullet, owned by Mr. H C. Stacey, Meadows.

It is generally found, too, that where the size of the egg is maintained with a 2oz. average after the birds have been in production for two to three months, the size and stamina of the stock, hatching, and rearing are of the high standard necessary for successful poultry keeping. In flocks where it is noticed that the size of the egg is definitely on the down grade, it will be found that the size of the bird is also smaller, with a general tendency towards a hereditary weakness in the progeny of that stock.

Further, the practice of weighing each egg has overcome many objections that competitors have to the block system of weighing. Prior to the introduction of this practice at Parafield, it was the custom to weigh all eggs during the month of July, and any bird which did not produce 66 per cent. of 2oz. eggs during the month of July was disqualified. This was a hardship to quite a number of competitors, in as much as that the birds which commenced laying steadily early in the test continued that production during April, May, and June, and frequently went into a light moult during July, with the result that they laid very few eggs during that period. It is well known in poultry breeding that, during a sequence of laying, the last eggs definitely show a decrease in weight, with a result that the method of weighing during the month of July meant that a number of good birds were disqualified.

Again, we frequently met the case of a very poor layer with four or five eggs to its credit during the month of July, but in many instances those eggs would weigh the required 2ozs., and the bird would be eligible to remain in the competition. These circumstances often resulted in discontent, and more or less suspicion among a number of competitors, but with the individual weighing of all eggs all this suspicion is removed, and the bird is only credited with the number of first-grade eggs.

In order not to penalise unduly the breeding of birds that will lay a reasonable number of first-grade eggs, the weighing has been arranged so that for the first two months of the test—that is, from the 1st April to the 31st May—a weight of 1¾ozs. is the minimum for first-grade eggs from the 1st to the 30th June 1⅞ozs. is the minimum for first-grade eggs, and from the 1st July to the 31st March the minimum is 2ozs. This gives the birds an opportunity of gradually reaching a production of the average 2oz. egg, while at the same time avoiding any undue strain in producing the full size 2oz. egg from the commencement of laying. Although this may be the aim of some breeders, I consider that from a commercial aspect it is more or less an ideal.



The Leading Black Orpington—233 first-grade Eggs.
Owned by Mr. J. Pennack, Pooraka.

The study of the results of Egg-laying Competitions will show that a big percentage of the mortality is due to straining in the early period of production, and keeping to the standard minimum 2ozs. from the commencement of laying undoubtedly accentuates this trouble.

Again, it should be kept in mind that birds invariably lay a bigger egg during the second and third year of production. Therefore, birds which come to the production of a 2oz. egg at the commencement of laying in their first laying period would probably increase that size to 2⅛oz. or 2¼oz. eggs during the second and third laying period, and it is extremely doubtful whether there is any commercial advantage in this aspect.

A study of the local marketing conditions and also the demand from overseas show that the definite preference is for the 15lb. pack, which is the average 2oz. egg. As export packing in South Australia does not seriously commence until July it should be the aim of producers to breed for the production of the 2oz. egg early in that month.

All eggs were collected at Parafield twice daily, at 11 a.m. and 4 p.m., and were weighed immediately following collection.

Poultry breeders supported the Competition well with the following number of birds:—

1935-36 *PARAFIELD EGG-LAYING COMPETITION.*

SECTION 1.—*Wet Mash.*

Class	Breed	No. of Entries.	
1.	White Leghorns	306	
2.	Any other light breed	6	
3.	Black Orpingtons	45	
4.	Any other heavy breed	36	
		—	393

SECTION 2.—*Dry Mash.*

Class	Breed	No. of Entries.	
5.	White Leghorns	18	
6.	Any other light breed	(no entries)	
7.	Black Orpingtons	3	
8.	Any other heavy breed	3	
		—	24

HOME PROJECT UTILITY SECTION.—*Wet Mash.*

Class 9.		
White Leghorns	24	
Black Orpingtons	10	
Rhode Island Reds	3	
Minorca	1	
	—	38
		455

It is interesting to note the increase in the number of entries received for the Home Project Utility Section. This section is available to scholars at the public schools who take up poultry as their home project, and it is indeed pleasing to see the increased interest which is being taken by the scholars in this particular work. Ultimately this must be of benefit to the poultry industry, particularly in the country districts where the majority of entries in this section comes from. Some of the scholars who have practised poultry as their home project are making very definite headway with poultry keeping as a means of livelihood, and there are already several boys in various parts of the State, who have graduated through the Home Project Class, with fine flocks of birds.

WINTER TEST.

The practice as adopted in previous competitions conducted at Parafield Poultry Station was again followed in the Competition under review, *i.e.,* Certificates were given to the birds which laid the highest number of first-grade eggs during the period from the 1st April to the 31st July, or 122 days. The winter test is one the importance of which should not be overlooked by poultry breeders. It should be understood that the egg-laying year is accepted in the poultry world as being from 1st April to the 31st March, and it is essential for a bird to record a reasonable score during the winter period to have any chance of a good score for the 12 months.

I believe that during the last few years when mass production of poultry has been practised, the importance of reasonable winter egg production has been overlooked. During the last five or six years, when there has been a good demand for day-old chicks, stock, &c., a number of breeders have turned their minds to the supply of this class of stock, and have placed the average egg production more or less as a secondary consideration. However, this state of affairs cannot continue indefinitely, as after all the stability of the poultry industry in South Australia depends on the returns received from egg production, and it is along these lines that the testing and breeding of stock must follow. The following table shows the leading birds in each section during the winter test:—

FIRST GRADE EGGS ONLY—WINTER TEST.

1st April, 1935, to 31st July, 1935 (122 days.)

SECTION 1.—WET MASH.

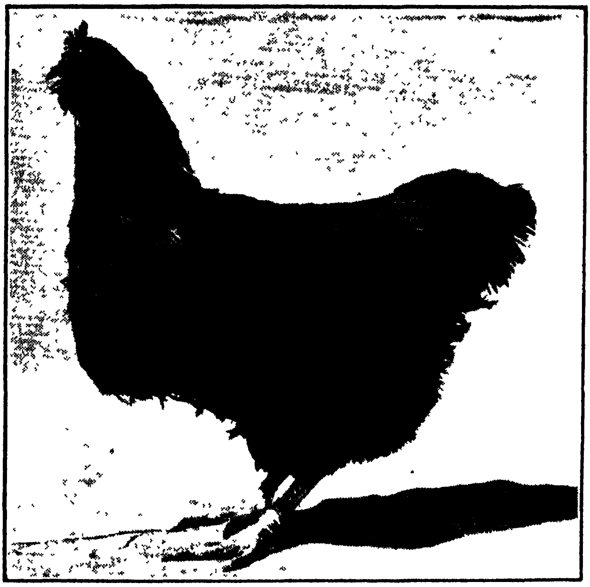
W. R. Christie	48	414

SECTION 3.—WET MASH.

Singles—

Olive Pitman, Gilles Plains (Black Orpington)	78	439
Lyol Stone, Morphett Vale (Black Orpington)	72	443
Peter Western, Ascot Park (White Leghorn)	71	415
Eric Pratt, Abattoirs (White Leghorn)	71	434
Malcolm Booth, Bridgewater (Black Orpington)	70	445



Rhode Island Red, the Winning Bird of "Any other heavy breed" section—218 first-grade Eggs. Entered by Mr. H. J. Mills, Edwardstown.

FEEDING.

The Competition was divided into two sections, one for Wet Mash and the other for Dry Mash. The Home Project Utility Section was Wet Mash; 431 birds were entered in the Wet Mash sections, and 24 in the Dry Mash section. As results in previous tests have shown, the leading scores in the Wet Mash sections are again in advance of those of the Dry Mash section. I have pointed out similar differences in previous Competitions conducted at Parafield. The competition results with regard to Wet and Dry Mash feeding also support the difference in results in experimental work conducted at Parafield.

The Wet Mash section was fed at approximately 7 a.m., and the method adopted was as follows:—Equal parts by weight of bran, pollard, and wholemeal, 1lb. of meat meal, and ½lb. linseed per 100 birds. The linseed meal was fed from the commencement of the test to 30th September, when it was dropped for the remaining period of the test. Greenfeed was added to the mash in proportions varying from 40 per cent. to 60 per cent. according to the season. Wheat was fed at midday and again at night on the basis of 1oz. at midday and 1oz. at night. The proportions of food in the Dry Mash were the same as those in the Wet Mash.

The Dry Mash was fed daily at 7.30 a.m., and at 10 a.m. greenfeed was given separately for Dry Mash birds.

The following table indicates the average monthly price of the various foodstuffs fed to the birds. These prices are on the basis of delivery at Parafield Poultry Station, and are those at which the average commercial egg producer is able to obtain his requirements:—

Average Monthly Prices of Foodstuffs.

Month.	Wheat Bush.	Bran per Ton.	Pollard per Ton.	Wholemeal per 60lbs.	Meat-meal per Ton.	Onions per Cwt.	Linseed meal per Ton.

The average cost of feeding per bird was 5s. 2d., which is a little higher than the 1934-35 test, when the cost was 4s. 8d. per bird.

PRICES RECEIVED FOR EGGS.

For the benefit of poultry keepers, and also of students of Egg-laying Competition results, the practice of publishing the monthly prices received for eggs is again followed. This table is one of the most interesting of the Competition series. The returns are published on a monthly basis, because that is the basis on which the eggs are sold.

It is again pleasing to see that, during the months of big production, *i.e.*, July to October, satisfactory prices were received, and from studying these figures poultry keepers will be assured that the prices for those months are practically overseas parity, for almost the bulk of the eggs during that period were sold overseas.

Once again I would point out the weakness in the present marketing system, as when production is falling rapidly—that is December and January--and the feeding costs are at their highest for the reason that the young stock are maturing rapidly at this period of the year, prices during these months show a downward tendency. This emphasises, as every test conducted in this State has shown, that the weakness in the egg-marketing position is during the months of December, January, and February. It should be the endeavour of all those actively connected with egg marketing to look for some other markets or some method of stabilising the market for those three months of the year. I believe that, in the near future, some system of market stabilisation will be essential if the industry is to progress from a State point of view.

The following table shows the monthly price received. The average price for the year for eggs 1⅞ozs. in weight and over was 1s. 0.31d. per dozen, as compared with 11.22d. for the year 1934-35, whilst the average price for 1¾oz. eggs was 10.43d. as compared with 9.12d. for 1934-35 test.

Monthly Price Received.

Profit Over Cost of Feeding.

The profit over cost of feeding should be considered satisfactory. I would, however, point out to those who follow the results closely, that it should be kept in mind that the competition birds are received at Parafield almost on the point of laying, and breeders must realise that there are feeding and rearing costs to be considered up to the time the birds commence production at the Competition. Many breeders, especially those just coming into the industry, are apt to overlook this fact.

Again, it must be understood that the birds are only kept at the Competition for their first laying year, which should be the most profitable year of their production. Further, in estimating costs of feeding and returns on the commercial farm, one must realise that the returns of laying birds for the second and third laying year are lower than they are during the first year of production.

All returns are slightly higher than the cost in the 1934-35 Competition, and it is to be hoped that these are indications of better prices for poultry breeders. The average return per bird was 15s. 5d., the cost of feeding 5s. 2d., leaving a return over cost of feeding of 10s. 3d. per bird for the full 12 months.

It is interesting to study the results since the commencement of the present system of individual weighing of eggs, that is, during the last three competitions:—

	1933-34.	1934-35.	1935-36.
Cost of feeding	4s. 6d.	4s. 8d.	5s. 2d.
Average price for eggs—			
1⅞ozs. and over	11·80d.	11·22d.	1s. 0·31d.
1¾ozs.	9·77d.	9·12d.	10·43d.
Return over cost of feeding	6s. 5½d.	9s. 8d.	10s. 2d.
Average number of eggs laid by competing birds	140	191·5	185·27

The low average for 1933-34 competition was due to the fact that this was the first year that the individual weighing of eggs was practised, and the breeders probably aimed at a lower egg production with the object of being reasonably sure of the weight of the eggs.

Home Project Utility Section Winning Bird, owned by Eric Pratt, of Abattoirs. Winning score, 240 first-grade Eggs. The same section was won by the same winner last year.

The next table is the most important of all, because it shows the total number of eggs laid by each bird, the number of first-grade eggs, and the number of second-grade eggs, together with the average of all eggs laid by birds which completed the test. In studying this table it will be seen that the White Leghorns produced the highest average number of eggs. During the previous two tests the Black Orpingtons won the pride of place, but they have dropped back from the average of 203 eggs in the 1934-35 test to an average of 182 eggs for the 1935-36 test. Barnevelders have again shown that almost all the eggs they produce are first grade eggs—from a total of 1,016 eggs laid, only 17 were second grade.

MORTALITY.

Mortality has shown a decided decrease on that of the previous test. This, however, may be due largely to the cool summer experienced during the competition with hardly a day when the birds were in any way distressed owing to heat, while in previous tests, owing to long heat waves, losses due to heat have been unavoidable. During the currency of the test 28 birds died from a total of 455 birds entered. This is equavalent to 6.15 per cent., and should be considered very satisfactory.

In the various breeds the death rate was as follows:—White Leghorns, 23 birds from 348 competing; Black Orpingtons, 2 birds from 58 competing; Rhode Island Reds, 3 birds from 36 competing. In the Minorcas, Cuckoo Leghorns, and Barnevelders no deaths were recorded.

Class.	No. Birds	Breed.	1st Grade Eggs Laid.	2nd Grade Eggs Laid.	Total Eggs Laid.	Average No. 1st Grade Eggs.	Average No. 2nd Grade Eggs.	Average all Eggs Laid.
1	286	White Leghorns....................	46,385	8,526	54,911	162·18	29·81	192·00

IMPORTANT DAYS

IN

South Australia's

Centenary Calendar

SEPT. 5 to SEPT. 12.

ROYAL SHOW

7 Days and 7 Nights.

ENTRIES CLOSE–

FRIDAY, JULY 3.

S.A. Industries and Manufactures, including Apiculture, Needlework, Knitting, Cooking, Artcrafts, etc. Dairy Produce.

THURSDAY, JULY 30.

Cattle, Sheep, Wool, Fat Stock, Horses (Heavy, Roadster, Blood), Swine Judging Competitions, Sheaf Tossing.

TUESDAY, AUGUST 4.

Poultry, Pigeons, Dogs, Eggs.

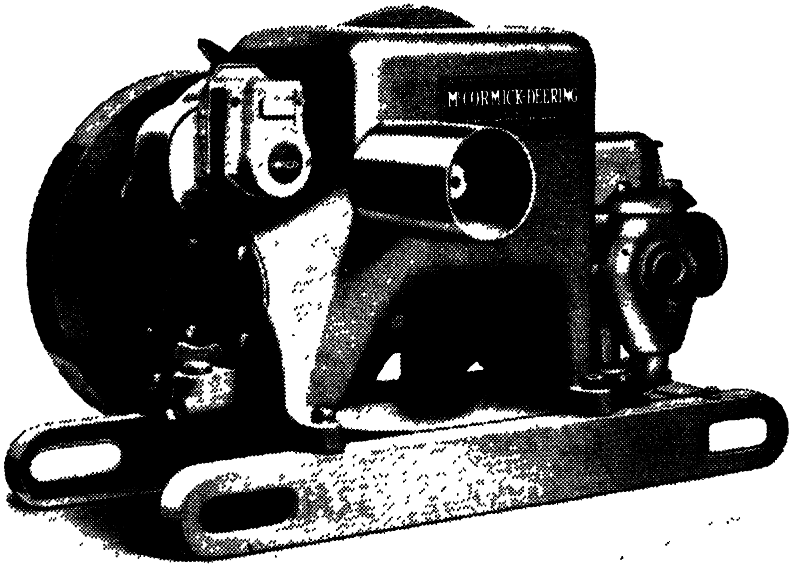
THURSDAY, AUGUST 6.

Horses-in-Action, Trotting.

Prize-Lists and Entry Forms are obtainable from the offices of the Royal Agricultural and Horticultural Society, Eagle Chambers, Pirie Street, Adelaide.

HAROLD J. FINNIS, Secretary.

Something NEW . . .
Worth seeing . . . Worth having



The New **McCORMICK-DEERING**
KEROSENE ENGINE
Two Sizes: 1½ to 2½ h.p. and 3 to 5 h.p.

IN THESE COMPACT NEW MODELS we offer you all-star engines for all farm work. They have variable power ratings—1½ to 2½ h.p. and 3 to 5 h.p.—and are qualified to do their full share of work in each power class, spreading their great usefulness over a wide range of duty. They are quality engines throughout . . . featuring high-tension Wico magneto, variable-speed throttle governor, suction feed, replaceable bearings, fully automatic lubrication, and enclosed operating parts. All parts are well guarded against rain and dust, making these new McCormick-Deerings ideal engines for outdoor as well as indoor operation. Their small over-all dimensions and light weight enable you to place these engines in out-of-the-way corners and to transport them easily from job to job.

Be sure to see the new McCormick-Deering Kerosene Engines at the local agency. Or write us for specific information.

Peter Western, Ascot Park (White Leghorn)	234	415
Warren Hannaford, Paracombe (White Leghorn)	226	422
Peter Western, Ascot Park (White Leghorn)	225	416
Gordon Gallasch, Gilles Plains (White Leghorn)	224	437
Stanley Pratt, Abattoirs (White Leghorn)	213	435

The Red Comb Cup, donated by the Red Comb Egg Association, Incorporated, to the bird laying the highest number of first-grade eggs owned by a member of the Association, was won by Mr. A. J. Monkhouse, of Woodside. It is indeed very pleasing to see this breeder winner of the Cup. Mr. Monkhouse is one of the oldest commercial egg breeders in the industry, and a visit to his plant at Woodside is always a pleasure.

In the Home Project Section it is also interesting to note that Master Eric Pratt, of the Abattoirs School, who won this section in the 1934-35 competition, was again at the head of the section in the 1935-36 competition. The scores altogether in the Home Project Section were quite satisfactory; 13 birds from 38 entered gained a Standard Certificate.

STANDARD CERTIFICATES.

In the 1934-35 Competition the Department instituted a system of standard certificates. In order to qualify for these certificates a standard has been fixed as follows:—For light breeds 200 first-grade eggs, and for heavy breeds 180 first-grade eggs.

Of the 427 birds that completed the test 115 gained a Standard Certificate. This is equivalent to 27 per cent. of the birds that completed the test, and it is interesting to record that the percentage of the 1935-36 test is identical to that of the 1934-35 Competition.

GENERAL SUMMARY OF RESULTS.

Number of birds that completed the test	427
Average number of eggs laid	185.27

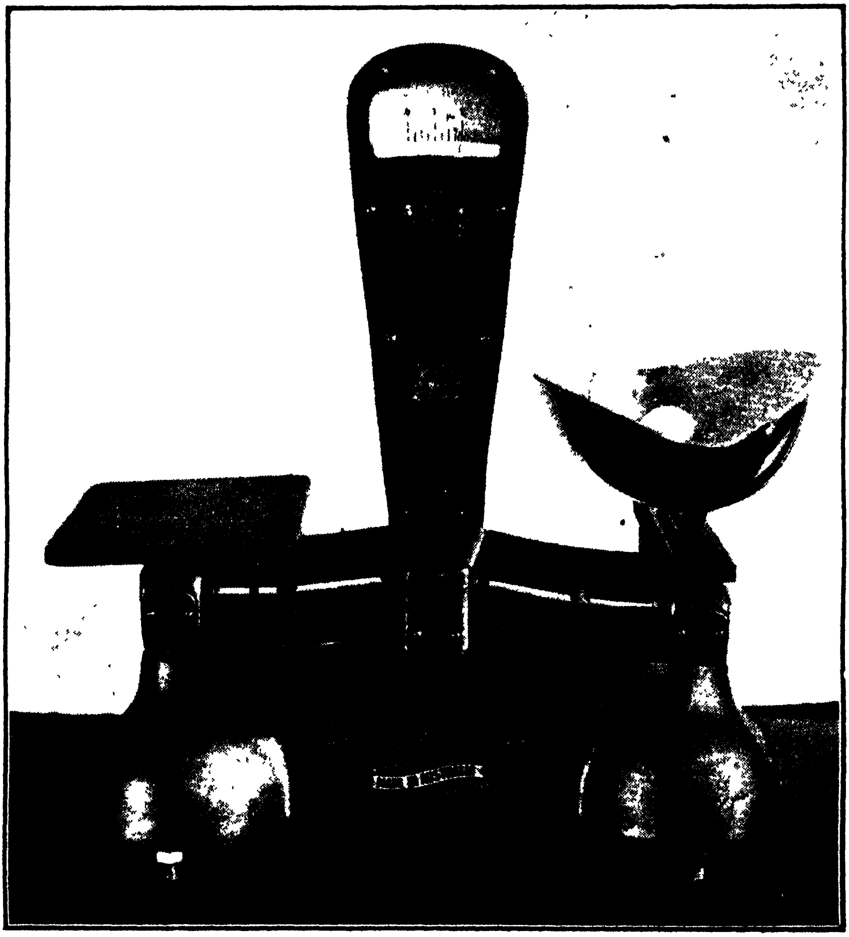
Averages of various breeds competing:—

Wet Mash Section—	Birds.	Eggs.
White Leghorns	286	192
Cuckoo Leghorns	3	186.66
Black Orpingtons	44	182.11
Home Project	36	176.52
Barnvelders	6	169.33
Minorcas	3	143.66
Rhode Island Reds	27	137.48
Dry Mash Section—		
White Leghorns	16	189.87
Rhode Island Reds	3	181
Black Orpingtons	3	177.66

Average cost of food per bird, 5s. 2d.
Average return per bird, 15s. 5d.
Return over cost of feeding, 10s. 3d.

TROPHIES.

The Red Comb Egg Association, Incorporated, was again instrumental in securing a very valuable set of trophies for winners of the various sections. Donations of these trophies are much appreciated by the Department, and are undoubtedly an incentive to the competitors, and it is a long time since such a fine assortment of trophies have been seen at the annual presentation as those presented by Hon. R. D. Nicholls, M.P. (Speaker of the House of Assembly), at a social evening held on Thursday, the 28th May.



In the Parafield Egg Laying Competitions each egg is carefully weighed to the fraction of one-eighth of an ounce, and the weight recorded on a special form.

The following firms donated trophies:—Messrs. Betteridge & Hall (egg-cleaning machine); South Australian Farmers' Co-operative Union (various trophies); B. J. Walters, Ltd. (clock); Parke Davis & Co., Ltd. (cup); Clarke, King & Co., Pty., Ltd. (Eggoleen cup); L. E. Saunders (watering system); Lanyon & Sons (watering system).

WHAT A PERFECT COMBINATION

FOR SPLIT-SECOND STARTING

VOLATILITY in petrol; FLUIDITY in motor oil—these are the two essentials for easy starting this winter. YOU GET BOTH by using Super Plume Ethyl and Winter Grade Mobiloil. This perfect combination for Winter motoring guarantees you Split-second Starting during the coldest days and nights. Avoid engine wear—save power—save petrol. During Winter—use this perfect combination.

Gear Oil: For Winter-ease gear shifting use the new Mobiloil "C"

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

STRATHALBYN CONFERENCE.

Branches of the Agricultural Bureau situated in the dairying districts met in Conference at Strathalbyn on Thursday, 21st May. Mr. C. M. Hudd presided, and the Department of Agriculture was represented by Messrs. P. J. Baily, A. J. Cooke, Professor A. J. Perkins (Advisory Board of Agriculture), W. J. Spafford (Director of Agriculture), H. B. Barlow, H. J. Apps, P. H. Suter, and H. C. Pritchard (General Secretary). The opening address was delivered by Mr. P. J. Baily.

"The Dehorning of Dairy Cattle" was the subject of a paper presented by Mr. J. Y. Hudd (Adelaide). Mr. C. Lund (Strathalbyn) contributed a paper entitled "Producing only Choice Grade," and Mr. J. R. Hewland (Adelaide) "The Milk Equalisation Plan."

Several questions of interest were answered by the officers present, and the following resolutions were carried:—(1) "That all resolutions and questions at future Dairy Conferences be taken immediately upon resuming after the luncheon adjournment." (2) "That this Conference suggests to the Department of Agriculture that five delegates be appointed from cream suppliers of the Dairymen's Association and five representatives from manufacturers, with an independent chairman, to confer for the purpose of arriving at means to eliminate the overlapping of transport of cream supplies." (3) "That this Conference suggests that the 10lbs. exemption in the Dairy Industry Act be cut out altogether, and that the Act be amended accordingly." (4) "As South Australia has the lowest agricultural Vote of all the States, that the Government be asked to increase the Vote." (5) "That legislation be enacted on lines similar to the Fertilizer Act to protect consumers against contaminated or adulterated bran and pollard." (6) "That the next Conference of Dairying Districts be held at Lobethal." (7) "That a stamp duty be organised to compensate producers for losses due to condemnation of all dairy cattle and pigs."

SOIL EROSION IN THE DRIER AUSTRALIAN INTERIOR.

The Council for Scientific and Industrial Research is now distributing copies of a report (Pamphlet 64) discussing soil drift and erosion in the arid interior and more particularly in the northern portions of South Australia.

It is pointed out that Australia might well learn a lesson from other countries, such as America, where soil erosion has lately developed into a most serious problem. In America, for instance, it appears that half the total area devoted to agricultural and pastoral pursuits has been adversely affected, and a large proportion of this area irreparably destroyed. In Australia, the trouble has not reached such proportions, but nevertheless it is quite evident that the time is fully ripe for something to be done to prevent any further damage.

Erosion of soils is caused by various agencies. An obvious type is the damage by gullying of paddocks, siltration of streams, &c., following deforestation of watersheds. Another type is caused by agricultural practices in the drier regions; trouble of that nature occurs in the Mallee. Yet another type is the erosion and creation of desert conditions in the drier pastoral areas, for example, those receiving not more than an average of 10in. of rain per annum in the arid interior of the Australian Continent. It is this last mentioned type of erosion that is discussed in the Council's pamphlet.

The report—which was written by Mr. F. N. Ratcliffe, B.A.—indicates that a large proportion of the area concerned has already been seriously eroded and much of the remainder is fast going the same way. It is mentioned, for instance, that some 90 per cent. of the saltbush area has been badly affected, but that a smaller percentage of the mulga areas is as yet seriously damaged. It seems that the trouble is due to the combined effects of overstocking, run of bad droughts, and the rabbit pest. Stock (and rabbits) for instance, kill off the vegetation and grasses (being particularly severe on seedlings) and then there is nothing left to bind the soil and to enable it to withstand disintegration and destruction by winds. In consequence over large areas the good soil is completely blown away, leaving a hard concrete-like subsoil on which no plant life can maintain itself. In other places the finer portions of the soil are blown away, leaving a sandy desert behind them.

Remedial measures are rendered most difficult by the fact that much of the area concerned is rarely worth as much as 2s. per acre in its virgin state. The main conclusion of the report is that a controlled and light stocking rate is the only hope of salvation, in other words, when the stocking is such as to be in equilibrium with the vegetation and not merely exploiting the plant capital. Nothing that the botanist may ultimately achieve can abolish the necessity of placing the stocking on a permanent and scientific basis. It is recommended that investigation along certain lines be initiated, including the search for extra sand-binding plants.

Some consideration is also given in the pamphlet to the effect of the rabbit in these arid areas. It is pointed out that the population of the pest fluctuates violently from year to year, increasing to plague numbers in the good years and diminishing to solitary individuals in the bad years. Despite the severity of the droughts, it seems improbable that the pest can ever be completly wiped out in these arid areas.

This latter statement, however, should not be construed, as has recently been done in some quarters, to mean that it is hopeless to expect to wipe out the rabbit in more favoured areas of Australia. In the first place, these areas have a greater capital value and can thus stand a greater cost of rabbit eradication. Further, they are much better placed for eradication, or at least the permanent reduction of rabbit population, by means of such agencies as wire netting, destruction of cover, dogging, and possibly disease. The Council is in fact enquiring into the possibilities of one disease, rabbit myxomatosis, which has been proved by Sir Charles Martin in Great Britain to be particularly effective against rabbits. Tests are now about to be made to ascertain whether it would be safe to spread the disease in Australia from the point of view of its possible effect on livestock and native animals.

INVESTIGATIONS INTO THE CONDITION KNOWN AS "FLOATING AND CLOUDY YOLK" IN EGGS.

[By C. F. ANDERSON (Government Poultry Expert) and A. E. PLATT, M.B., B.S., Dip. Bact. (London) (Deputy Director, Government Laboratory of Bacteriology and Pathology).]

During the past 12 months an abnormal condition has been found in eggs on the various egg floors. This condition is, for the purpose of this article, termed "Floating and Cloudy Yolk." It is quickly detected when the eggs are being candled, the first noticeable feature being the yolk appears a little darker in colour than that of the normal egg. The yolk is mobile, and floats to various positions in the egg. In some eggs it will go to the bottom, and in other cases it will go to the top. In a big percentage of these eggs the yolk gets gradually darker in colour according to the length of time the egg is kept.

Generally, the egg on being broken is, however, normal in colour. The white in most cases is normal, although in a few instances it is a little thin and watery. The yolk appears quite firm.

The number of eggs so affected was sufficient to warrant close investigation, and in this direction the Poultry Section of the Department of Agriculture of South Australia commenced detailed investigations. The work was started with the testing, each day, of all eggs laid in the Single Test competition conducted at the Government Poultry Station, Parafield, South Australia. This test comprised 427 birds, all in the first laying season, and the following breeds were represented:—White Leghorns, Cuckoo Leghorns, Black Minorcas, Black Orpingtons, Rhode Island Reds, and Barnevelders. Each bird was housed in a separate pen, and the birds were entered by breeders in various parts of the State. *The eggs were all tested immediately after collection and prior to being cleaned and packed for market purposes.*

A similar condition was reported by E. T. Halnan, M.A., and H. D. Day (1935). The incidence was very low, and it is doubtful whether the conditions were similar to those found in the Parafield investigations.

TESTING.

The work at Parafield was started in December, 1935, and the following table shows the results of the testing:—

Week Ending.	Total Eggs Tested	Tested as Floating and Cloudy Yolks	Per Cent. with Floating and Cloudy Yolks
Dec. 22nd, 1935	1,570	232	14.77
Dec. 29th, 1935	1,597	321	20.10
Jan. 5th, 1936 ..	1,727	461	26.69
Jan. 12th, 1936	1,709	531	31.07
Jan. 19th, 1936 . .	1,687	571	33.84
Jan. 26th, 1936 .	1,582	618	39.06
Feb. 2nd, 1936 . .	1,658	738	44.51
Feb. 9th, 1936	1,635	979	59.87
Feb. 16th, 1936	1,548	960	62.01
Feb. 23rd, 1936	1,451	963	66.36
March 1st, 1936	1,420	1,019	71.76
March 8th, 1936	1,393	1,092	78.39
March 15th, 1936 . ..	1,380	1,245	90.21
March 22nd, 1936 . ..	1,277	1,169	91.54
March 29th, 1936 . ..	1,147	1,078	93.98

Continuing the work of testing, it was decided to test the eggs of several private breeders. With that object in view, an officer of the Department visited breeders in several parts of the State, and the results of the testing on five of the largest farms are given. On all the farms, where eggs were tested, the results were practically the same as those obtained at Parafield. For record purposes, the farms are referred to as A, B, C, D, E. Farms A and B are situated in the Angaston district, C and D at Moonta Mines and North Yelta, and E at Murray Bridge. The result of the testing was:—

FARM A.—*Results of Testing.*

Week Ending.	Total Eggs Tested.	Tested as Floating and Cloudy Yolks.	Per Cent. with Floating and Cloudy Yolks.
12/2/36	250	233	93.2
19/2/36	250	242	96.8
26/2/36	250	244	97.6
4/3/36	250	248	99.2
11/3/36	250	250	100
18/3/36	250	238	95.2
25/3/36	200	200	100
1/4/36	250	250	100
8/4/36	250	250	100
15/4/36	250	250	100
22/4/36	250	250	100

The feeding adopted at Farm A was as follows:-

Morning: Wet mash composed of 2 parts pollard by measure, 1 part bran by measure, ½lb. meat meal per 100 birds, ¼lb. Meggitt's linseed meal per 100 birds, ¼lb. tobacco dust per 100 birds; 25 per cent. to 30 per cent. greenfeed to every 100lbs. mash in the morning. Mash was mixed with separator milk.

Midday and Night: Wheat.

The birds had free range for three or four hours each day. The age of the birds was from 18 months to 3 years.

FARM B.—*Results of Testing.*

Week Ending.	Total Eggs Tested.	Tested as Floating and Cloudy Yolks.	Per Cent. with Floating and Cloudy Yolks.
12/2/36	250	250	100
19/2/36	250	249	99.6
26/2/36	250	248	99.2
4/3/36	250	250	100
11/3/36	250	250	100
18/3/36	250	250	100
25/3/36	216	216	100
1/4/36	288	288	100
8/4/36	338	338	100
15/4/36	250	250	100
22/4/36	250	250	100

The feeding adopted at Farm B was as follows:—

Morning: Wet mash composed of:—Bran, 1 part by weight; pollard, 2½ parts by weight; meat meal, ½lb. per 100 birds; key meal, ½lb. per 100 birds; tobacco dust, ¼lb. per 100 birds; buttermilk powder, ¼lb. per 100 birds; chaffed lucerne, 30 per cent. The mash was mixed with separator milk.

Midday: Wheat.

Afternoon: Chaffed lucerne.

Night: Wheat.

The birds were allowed free range each afternoon. The age of the birds was 1, 2, and 3 years.

Farm C.—*Results of Testing.*

Period Ending.	Total Eggs Tested.	Tested as Floating and Cloudy Yolks.	Per Cent. with Floating and Cloudy Yolks.
12/2/36	100	81	81
17/2/36	241	219	90.8
19/2/36	350	336	96.8
26/2/36	350	331	94.5
4/3/36	300	269	89.6
11/3/36	300	291	97
18/3/36	300	287	95.6
25/3/36	200	199	99.5
1/4/36	350	334	95.4
6/4/36	350	347	99.1
15/4/36	350	350	100
22/4/36	360	357	99.1

The feeding adopted at Farm C was as follows:—

Morning: Wet mash composed of:—Bran, 1 part by measure; pollard, 3 parts by measure; whole grain (wheat), 9 per cent.; meat meal, 3 per cent.; linseed meal, 3 per cent.; greenfeed (lucerne), 18 per cent. Morning mash mixed with hot water containing 4ozs. of fine salt.

Midday: Wet mash composed of:—Bran, 25 per cent.; pollard, 30 per cent.; wheat, 10 per cent.; greenfeed, 35 per cent. Midday mash mixed with cold water.

Evening: Wheat.

Farm D.—*Results of Testing.*

Period Ending.	Total Eggs Tested.	Tested as Floating and Cloudy Yolks.	Per Cent. with Floating and Cloudy Yolks.
12/2/36	300	286	95.3
26/2/36	288	267	92.7
6/3/36	216	207	95.8
25/3/36	180	179	99.4
1/4/36	360	358	99.4
6/4/36	360	360	100
15/4/36	360	360	100
22/4/36	350	350	100

The method of feeding adopted at Farm D was as follows:—

Morning: Wet mash composed of:—Bran, 1 part by weight; pollard, 2 parts by weight; chaffed lucerne, 20 per cent.; meat meal, ¾lb. per 100 birds; linseed meal, ¼lb. per 100 birds; charcoal grit, ¼lb. per 100 birds. Mixed with separator milk.

Midday: Grain (equal parts wheat and barley).

Night: Grain (three parts wheat, 1 part barley).

Farm E.—*Results of Testing.*

Period Ending.	Total Eggs Tested.	Tested as Floating and Cloudy Yolks.	Per Cent. with Floating and Cloudy Yolks.
10/2/36	237	235	99.1
14/2/36	221	213	96.3
21/2/36	146	146	100
2/3/36	200	200	100
11/3/36	250	250	100
16/3/36	214	209	97.6
30/3/36	220	220	100
8/4/36	300	300	100
14/4/36	250	250	100
20/4/36	250	250	100

The method of feeding adopted at Farm E was as follows:—

Morning: Wet mash composed of:—Bran, 1 part by weight; pollard, 3 parts by weight; meat meal, 8 per cent.; key meal, 11 per cent.; charcoal, 5 per cent.; pestend, 2 per cent.

Afternoon: Wheat at rate of 1¾ozs. per bird.

Night: Chopped greenfeed at rate of 7lbs. per 100 birds.

No greenfeed was fed in the morning mash. The birds were housed on the semi-intensive method in units of 30 birds.

The above figures indicate the extent of this particular trouble, and show that it is widespread. There is one particularly noticeable feature, and that is the large number of eggs which test apparently normal immediately after laying and develop the condition within three or four days.

HEALTH OF STOCK.

From general observation of the stock, there does not appear anything wrong with them. They appear to be in normal health; the laying apparently is not affected, as production has been maintained at a reasonable level.

EFFECT ON HATCHING.

With a view to testing the effect, if any, on hatching of eggs showing, on candling, the condition of floating and cloudy yolks, three lots each of 100 eggs were incubated with the following results:—

	No. Eggs Set.	No. Chicks Hatched.
Batch No. 1	100	81
Batch No. 2	100	77
Batch No. 3	100	69

From the above results it will be seen that the eggs hatched well. The chickens were particularly strong and active, and are being kept for research purposes.

FEEDING.

In the early stages of the trouble, it was thought that probably feeding may have an important bearing on the subject, and all wheat fed at Parafield Poultry Station for a period was sterilised. A portion of the sterilised wheat was crushed and fed together with greenfeed and meat meal, the balance of the wheat fed as whole grain. No noticeable difference was, however, found in the condition of the eggs on being candled.

EFFECT ON THE KEEPING QUALITIES OF THE EGGS.

A considerable amount of work was carried out in this direction, and is being continued. Hundreds of dozens of the eggs in this condition have been placed in cool storage, and have been tested almost every week. In the majority of instances, the only noticeable difference on candling is that the yolks in a small percentage of cases go a little dark in colour, but in almost every instance the eggs when broken on a plate appear quite normal in colour of yolk and white, and do not carry any trace of taint.

For the past four years the Department of Agriculture has carried out investigations into the question known as "Watery White" in eggs. A progressive report has been published on this subject in Bulletin No. 308 issued by the Department (1936). The condition, however, referred to in this article as "floating and cloudy yolks" appears to be, from candling, an entirely different one from that of "watery white."

EXPERIMENTAL WORK.

As a preliminary investigation a chemical estimation of the protein content of the white of these eggs was made. The estimations were made (by Mr. R. J. Cowan, of the Government Laboratory of Bacteriology and Pathology) on adequate samples taken from the pooled whites of three dozen "floating yolk" eggs, and the results compared with those obtained in similar estimations on the pooled whites of three dozen eggs passed for export. The results of these estimations were as follows:—

	Protein Content of Egg-white. Per Cent.
(i.) Eggs passed for export	10.6
(ii.) Eggs rejected (floating yolk)	11.0

Non-protein nitrogen estimations were identical for both batches, being approximately 25 milligrams per 100 c.c. egg-white.

These results indicate that there is no difference in protein content of the whites of the eggs and, in this respect, the condition differs from that known as "watery white."

CHANGES NOTED IN EGGS WITH "FLOATING YOLKS."

Besides the excessive degree of mobility of the yolk which is diagnostic of this condition, two other phenomena can be observed in a large percentage of these eggs. Frequently, especially when the eggs have been kept in cold storage for some time, the shadow of the yolk appears much darker than that usually produced by the yolk in this condition. The most interesting observation in connection with the candling of these eggs was that in many cases the shadow of what appeared to be an appendage to the yolk was clearly visible.

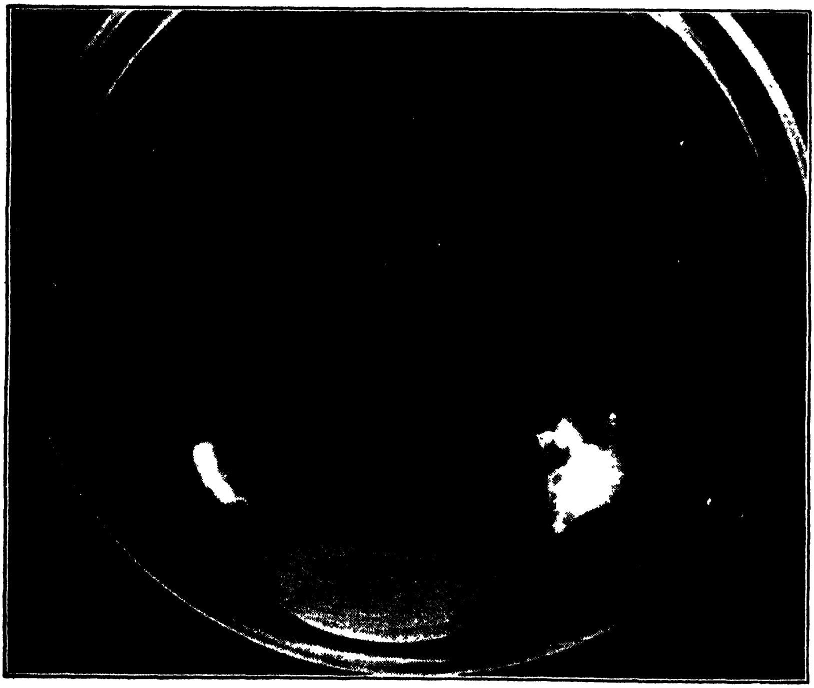

FIG. 1.—Showing thickened ligaments and the slight opacity which surrounds the yolk.

When such eggs were broken, often little change was apparent. In many instances the yolks appeared normal in colour. In others there was a definite darkening of the yolk which, in many cases, was associated with a partial coagulation of the proteins giving the yolk an appearance of candied honey or lemon-cheese. In a few cases, besides this partial coagulation of the main mass of the yolk, small plaques of dried, or inspissated yolk were found adherent to the vitelline membrane.

In many eggs the white appeared normal, but in a large percentage there was a zone of semi-opaque white surrounding the yolk (Fig. 1). This zone was most frequently seen in eggs which, upon candling, showed a darker yolk than usual.

The most striking change, however, and one which was present in all affected eggs, was noticed in connection with the chalaza or suspensory ligament of the yolk. One, or sometimes both, showed considerable enlargement with marked increase in opacity of the egg-white immediately surrounding it (Figs. 1 and 2). The end nearest the shell was always ragged in appearance, and showed signs of partial digestion.

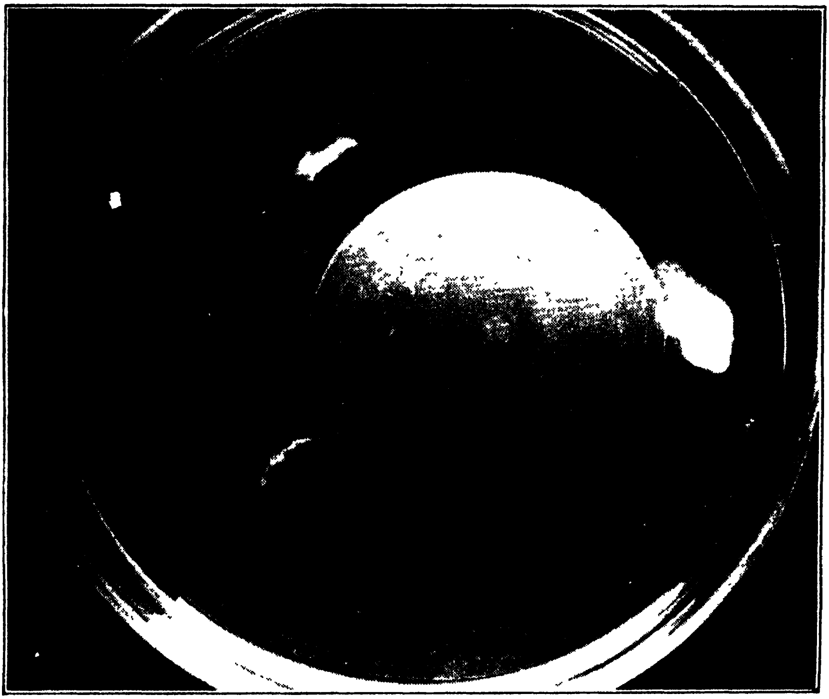

FIG 2—Showing one thickened ligament Compare with normal ligament at opposite pole of yolk.

From observations it seemed fairly clear that the thickened condition of the chalaza was related to the "floating yolk" condition, and on this assumption the investigations described below were made with the object of elucidating the nature of this pathological change in the chalaza.

Paraffin sections of the chalaza were prepared and stained with haemotoxylin and eosin. In suitably cut sections, where the suspensory ligament was cut transversely across, masses of rod-shaped organisms could be seen in the interior of the chalaza (Fig. 3). By suitable means this organism was recovered in pure culture (*see* Platt, 1936). It was a Gram-positive rod-shaped motile organism which under adverse conditions formed oval subterminal spores.

The appearance of this organism on culture media was very characteristic (see Platt, 1936), and although it was impossible to name this organism it could at least be placed in the Genus *Bacillus*.

An interesting observation concerning the spores of this organism is that they can withstand boiling in water for five minutes.

Attempts were now made to reproduce the "floating yolk" condition in eggs of hens in which up till the time of carrying out the experiments no abnormality had been detected. Owing to the difficulty of obtaining birds laying normal eggs, only 12 birds were available for these experiments. These birds were divided into three groups, two of which were kept at the Government Poultry Farm at Parafield, and the other group brought to the Government Laboratory of Bacteriology and Pathology.

During the experiments the hens were fed on wheat sterilized by autoclaving, crushed grain prepared from autoclaved wheat, and lucerne locally grown. Drinking water was obtained from the main supply or from tanks. Spores of the bacillus were added to the drinking water, and also each bird received, each day, a pellet of sterilised wholemeal to which spores had been added, for five consecutive days. During the whole period of observation the birds remained perfectly healthy, but in periods ranging from two days to a fortnight all the birds commenced laying "floating yolk" eggs. In birds laying regularly every day, the second or third egg laid after the commencement of the experiment showed the "floating yolk" condition. In two or three birds no egg was laid for more than a week, and in these cases the first eggs laid after commencement of the experiment possessed "floating yolks." A number of these "floating yolk" eggs laid during the experiments were examined bacteriologically, and the characteristic bacillus recovered from the thickened chalaza.

FIG. 3.—Showing masses of organisms in cavity of suspensory ligament.

Throughout all these observations the healthy condition of the hens was striking. In order to see whether any lesions were present, four hens laying "floating yolk" eggs were killed and examined *post-mortem*. No abormality of any kind could be detected. Cultures were made from the oviducts of three of the birds. In two cases they were negative, but in the remaining one a pure culture of the bacillus was obtained from the upper portion of the oviduct.

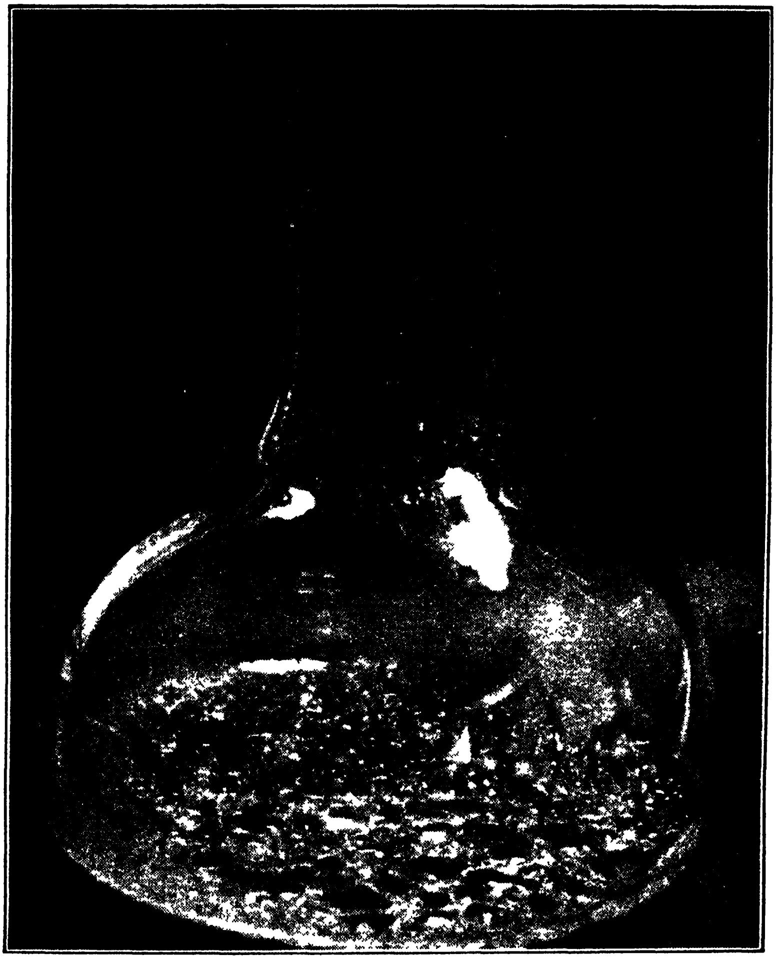

FIG. 4.—Broth culture (24 hours) of organism isolated from suspensory ligament, showing pellicle formation

DISCUSSION.

The widespread distribution of this condition and the rapid increase in its incidence in various localities are rather puzzling, and as yet it is not possible to offer any explanation. The relationship of the bacillus recovered from the chalaza of affected eggs to the "floating yolk" condition is also not quite clear. Whether it is the sole and primary cause or whether its role is only that of a secondary invader, following some biological disturbance or other bacterial infection, has still to be determined. With this proviso we might postulate an hypothesis as to the means by which this bacillus gains admission to the eggs and the part it plays in producing the "floating yolk" condition.

The organism is probably taken into the alimentary tract in the spore form, and possibly germinates there, whence it passes *via* the cloaca to the oviduct. There it becomes incorporated in the chalaza before the white is added to the yolk. In the chalaza, in the course of its metabolism, it produces an enzyme capable of digesting protein, and this enzyme brings about a dissolution of portion of the chalaza which, rupturing, allows the yolk to float freely. Further investigations are being made to determine the correctness or otherwise of this hypothesis, and also to endeavour to discover a method of treatment. A few experiments using living and killed vaccines have been performed with disappointing results so far.

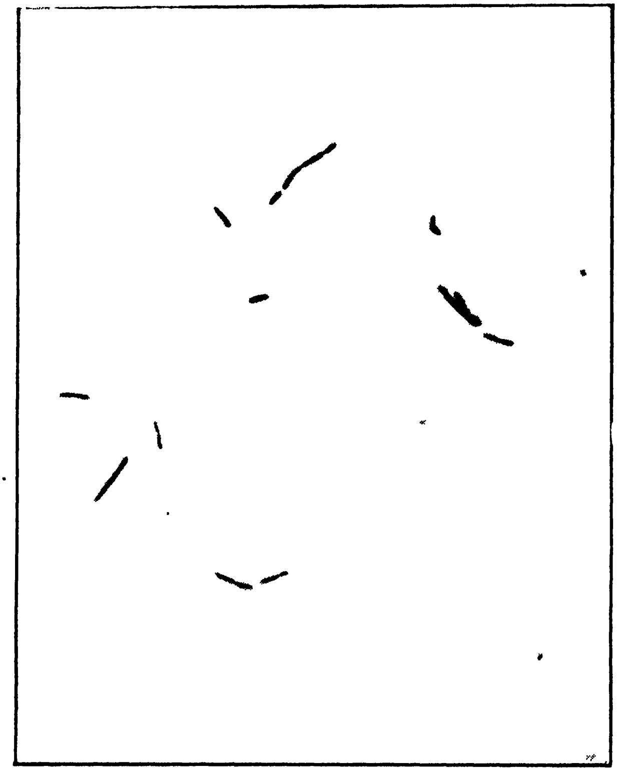

FIG. 5.—Film (gram stain) of organism isolated from suspensory ligament (X 1100)

SUMMARY.

1. A condition in eggs known as "floating yolk" is described, and the incidence and distribution are discussed.

2. A Gram-positive motile spore-forming organism can be recovered from a large percentage of affected eggs.

3. When birds, which were laying normal eggs, were fed with spores of this organism they commenced laying "floating yolk" eggs.

4. The role of this organism in connection with the "floating yolk" condition is discussed.

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April, 1935 to 31st May, 1936.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal, 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 30th April, 1936.	No. Eggs Laid Month of May, 1936.	Total Eggs Laid 1st April, 1935, to 31st May, 1936.
No. 1 Test	7,698	195	7,893
No. 2 Test	7,885	180	8,065
No. 3 Test	8,509	191	8,700
No. 4 Test	6,913	100	7,013

A REVIEW OF THE PAST FRUIT DRYING SEASON ON THE IRRIGATION AREAS.

[By F. R. Arndt (Horticultural Instructor).]

The most noteworthy feature of the early part of the season was the comparatively light flowering of the Sultana vines in most vineyards.

Judging by the number of bunches on the vines, many growers early in the season estimated that their Sultana crops would be from 30 to 50 per cent. lower than the previous year, but as the smaller number of bunches was in many instances counterbalanced by a better setting of berries, making for tighter and heavier bunches, a better crop resulted than was at first anticipated.

Vineyards in which Sultana vines flowered well were chiefly those that had suffered some frost damage—but not of an excessive nature—during the previous season, and consequently in which the strength of the vines had not been depleted by the heavy cropping. Currant and Gordo Muscat vines flowered well, and a good setting of berries followed. As regards deciduous trees, the setting of apricots was not as heavy as the previous season, but peaches generally set good crops.

No spring frosts of a serious nature were experienced, and no frost damage to crops was incurred.

Heavy January Rains.

Indications during the spring and early summer months pointed to the production of satisfactory crops, but early in January heavy monsoonal rains occurred, averaging 3in. to 5½in., according to locality. These had the effect of seriously damaging currant grapes and a portion of the apricot crop. A considerable proportion of the apricot crop had been harvested prior to the rains, and so escaped injury, but where freshly-cut fruit became wet by rain, or remained moist as a result of the unusual humidity of the air, considerable damage from mould resulted, while much of the fruit still on the trees either crocked or collapsed.

Damage to the Currant Crop.

Of the various fruits currant grapes suffered most severely from the rain, which caused ripened berries to split and mould to form in the centres of bunches. The losses sustained varied considerably in different vineyards, chiefly on account of varying degrees of ripeness of the berries, being as high as 80 per cent. and over in places, while in other holdings the losses were comparatively light. All berries that were ripening and which had commenced to colour split badly, whereas fruit that was in the hard, green state practically escaped rain damage. This feature was very marked on the properties of several Berri growers whose vines are situated in frost pockets and who, to avoid frost losses, pruned early in September. The result was that the fruit was still quite green when the rain arrived, and so practically suffered no injury from this cause.

Late pruning, however, cannot be regarded as a means of saving fruit from rain damage, as rain may occur at any time, and had the rains this season taken place several weeks later the fruit on the late-pruned vines would also have been damaged. In the aggregate, fruit losses sustained by the currant vines were about 50 per cent. or a little more of the crop.

During harvesting, totally damaged bunches had, of course, to be discarded, and only those that were reasonably free from mould could be selected. As in many instances the bunches were only partially damaged, only the good portions of these could be harvested, and the mouldy parts had to be cut out. This necessity made harvesting operations slow and costly, and difficulties were also encountered when spreading the fruit on to the racks, as damaged bunches that had been overlooked in picking had to be rejected. Considerable care had also to be exercised when removing the fruit from the drying racks, as numerous dry lumps of moulded fruit were common, and these had to be discarded when boxing up. This culling was done either by hand picking or by running the fruit through a coarse sieve before delivery to the packing houses for grading and further treatment.

The Sultana Crop.

The rain which so seriously damaged the currant grapes did not have a similar detrimental effect on the sultana crop, although slight splitting of sugared berries occurred in places, and black spot attacked the berries of vines situated in low-lying positions on several vineyards. The great bulk of the crop, however, was in very good condition during the earlier part of the season, and some very good samples of dried fruit were produced during that period.

Later in the season, however, from 60 to 70 points of rain fell, and this had the effect of slightly splitting a number of berries near the stem end. Although hardly noticeable when picking, this injury showed up after the fruit had been dipped, and resulted in a much darker sample of dried fruit than was produced earlier in the season.

Sultana Dips.

The "battle of the dips" still continues, and the ideal of a "fool-proof dip" has not yet been evolved. During the past season sultana grapes have been processed by means of the cold potash dip, the standard mixed dip, the caustic modified hot dip, and occasionally even by the boiling caustic dip. During the early part of the season the majority of the growers made use of the standard mixed dip, and a much smaller number of the cold potash dip.

Owing to the inspection of dried fruit at the packing houses being more stringent this season than usual in regard to green tinge on sultana berries, a considerable quantity of fruit was rejected at one period and sent back to the growers for further bleaching. This had the effect of causing a number of growers to treat the remainder of their fruit by means of the modified hot caustic dip, by which process a more amber but somewhat darker sample of dried fruit was produced than by the use of the standard mixed dip.

As the highest prices on the English market are realised by sultanas of a light golden colour, it should be the object of the grower whenever possible to produce this class of dried fruit. It is therefore a retrograde step for growers to adopt a dipping process which will give a darker sample of dried fruit than they have previously produced.

Removal of the Green Tinge.

During recent years a number of growers have experienced considerable difficulty in removing the green tinge from the dried sultana berries when the fruit has been processed by either the cold potash or mixed dip methods. The chief causes of fruit remaining green after it has been dried are either too early picking or insufficient bleaching.

In regard to early picking many growers in their haste to complete their harvest gather their fruit before it is sufficiently ripe. If sultana grapes are harvested when the surgar content has reached 12 degrees Baume a satisfactory sample of dried fruit is generally obtained if weather conditions during the drying period are favourable, but if the fruit is picked when the sugar content is one or more degrees Baume below this figure, then not only will the fruit dry out much lighter in weight, but will generally be much greener in colour as well.

COMING SOON—A NEW
"CATERPILLAR" DIESEL FARM
TRACTOR—THE "RD4."

Smaller than any of the Diesel tractors that have, until now, been included in the "Caterpillar" line, the "RD4" extends Diesel economies to new thousands of power users.

Let us send you particulars of this new model which marks another important advance in "Caterpillar" leadership.

The popular Models "Twenty-two" and "Thirty" (for kerosene) will continue as at present.

Illustrated Catalogue posted with pleasure. Address your letter—

THE S.A. TRACTOR COMPANY,

Box 524E G.P.O., Adelaide. Showrooms: 231, Flinders St., Adelaide.

THERE IS ONLY ONE "CATERPILLAR.."

THE "HOME" TRAIN.

Work over for the day, man and maid, young and old are intent upon "getting home." All day they have been concerned with business, mostly someone else's business, for the majority of the homeward-bound travellers are salary or wage earners.

Have they—have you—found time for personal business.

The Commonwealth Savings Bank is open all day in City, Town, Village and Country Post Office, and its convenient services are therefore easily available to all.

Opening a Savings Bank account—and using it—costs little time and no money, and it will pay you well in the long run.

Commonwealth Savings Bank of Australia

A. W. SANDFORD & Co., Limited,
Grenfell Street, Adelaide.

With fruit that is reasonably mature before harvesting, not much difficulty will be experienced in bleaching out any green tinge it may have after it has been removed from the drying racks and placed on hessians or "Sisalkraft" to finish off in the sun. It is, however, with sultanas processed from insufficiently ripened fruit that the green tinge is difficult to remove, even after exposure to the sun on hessians for several days. In such cases, if the fruit is well moistened with water, allowed to sweat by being bundled up in hessians for several hours during the heat of the day, and then spread out again, a considerable amount of browning will take place, while, while overcoming the green tinge, will nevertheless not give that clear golden colour that may be obtained from better-ripened fruit.

Washing Cold-dipped Fruit.

To obtain the best results from the cold potash method the fruit, after its removal from the drying racks, should first be spread on hessians placed in the sun to get quite dry. It should then be washed in a potash solution of about 1 degree Beaume strength to which has been added 1 to 1½ pints of olive oil per 50galls. of water, and again placed on hessians in the sun to complete the drying process. This washing not only removes much of the surplus potash adhering to the berries, but it also has the effect of assisting the removal of the green tinge from the fruit.

The Gordo Crop.

Commencing with a good flowering and setting of fruit, and helped later on in the season by comparatively mild summer weather, which did not to any appreciable extent scorch the berries (as is often the case during very hot summers), Gordo vines this season produced the most prolific crops experienced for a number of years. Although much of the fruit found its way into the wineries, owing to the present good demand for Muscat grapes for winemaking, there was still a considerable quantity dried for lexias.

In preparing the fruit for drying the dipping processes used were either those of the modified hot caustic dip method, at temperatures varying from 190 degrees to 200 degrees Fahr., or the standard mixed dip process, at a temperature of about 190 degrees Fahr. Owing to fine, dry autumn weather, conditions were very favourable for the drying of Gordo grapes, and resulted in a good average sample of dried fruit being obtained.

STATE OF SOUTH AUSTRALIA.

FINAL RESULTS OF CEREAL AND HAY HARVEST, 1935-36.

[A. W. Bowden, Government Statist.]

Wheat, 1935-36, 31,615,744bush.; average per acre, 10.58bush.

Wheat, 1934-35, 27,455,600bush.; average per acre, 8.61bush.

There are still a few minor wheat districts where the completion of the collection has been delayed, and a number of odd returns from farmers in other districts outstanding, but, rather than further delay the final results, a safe estimate has been made for all these, and hence the totals now submitted may be accepted as final.

I. SURVEY OF CONDITIONS.

It will be remembered that the official estimate of the wheat harvest published in December, 1935, was 32,300,000bush., being based on reports received during the first week in December. The decrease of nearly 700,000bush. to the final result now published (31,615,744bush.) is more than accounted for by the decrease in the Western Division, where take-all and rust became more prevalent than expected, and where thunderstorms with heavy winds and rains caused loss by shedding and bleaching. In the other Divisions of the State, the reports indicate that wheat was not so badly affected by the storms, and barley was only affected to a slight extent, the actual yield being 6,493,983bush. compared with the estimate of 6,800,000bush. Oats, however, were badly affected in every Division, the losses being so severe that only 2,380,908bush. were harvested compared with the estimate of 3,150,000bush. The hay crop was estimated at 600,000 tons, and 575,471 tons were cut.

II. GROWERS AND ACREAGE SOWN.

Wheat Growers.—There were 13,790 (14,201) growers of wheat for all purposes for the season 1935-36, and of this number 12,713 (13,053) reaped areas for grain. Approximately 1,765 (1,759) reaped areas of under 50 acres. Sharefarmers counted once only.

Acreage.—The grand total acreage sown to wheat, barley, and oats for all purposes was 4,317,146 (4,497,481) acres, a decrease on the previous year of 180,335 acres.

Wheat.—3,210,238 (3,459,380) acres: Grain, 2,989,490 (3,188,225) acres; hay, 213,703 (264,373); fed off, &c., 7,045 (6,782).

Barley.—414,419 (334,462) acres: Grain, 393,741 (316,807); hay, 3,389 (3,128); and fed off, 17,289 (14,527).

Oats.—692,489 (703,639) acres: Grain, 299,771 (367,192); hay, 334,529 (280,710); fed off, &c., 58,189 (55,737).

III. PRODUCTION AND AVERAGES PER ACRE.

Wheat.—31,615,744bush. (27,455,600bush.), increase 4,160,144bush., averaging 10.58bush. (8.61bush.) per acre.

Barley.—6,493,983bush. (5,682,923bush), increase 811,060bush., averaging 16.49bush. (17.94bush.) per acre. This yield exceeds the previous record crop of 6,070,161bush. in 1932-33.

Oats.—2,380,908bush. (2,412,117bush.), decrease 31,209bush. on previous year's record, averaging 7.94bush (6.57bush.) per acre.

Hay (wheaten, oaten, and barley).—575,471 (550,020) tons, increase 25,451 tons, averaging 1.04 (1.00) tons per acre. Distributed as follows:—Wheaten 246,164 (298,896), oaten 326,371 (247,603), barley 2,936 (3,521) tons.

IV. BENEFITS FROM FALLOWING.

Of last season's wheat crop 2,095,668 (2,233,258) acres sown on fallow yielded 26,846,254bush. (24,608,163bush.) averaging 12.81bush. (11.02bush.) per acre, and 893,822 (954,967) acres sown on unfallowed land yielded 4,769,490bush. (2,847,437bush.) averaging only 5.34bush. (2.98bush.) per acre, thus making the State average 10.58bush. (8.61bush.) per acre.

FINAL RESULTS OF CEREALS AND HAY, 1935-36.

Wheat, 1935-36—Acres, 2,989,490; yield, 31,615,744bush.; average, 10.58bush.

Wheat, 1934-35—Acres, 3,188,225; yield, 27,455,600bush., average, 8.61bush.

VI. The Marketing of the Crop.

The carry forward was 1,500,000bush., and with the 1935-36 crop a total of 33,100,000bush. was available; 3,250,000bush. are required for seed, and probably 4,750,000bush. for home consumption, including feed for stock and a three months' supply carry forward before the next crop is matured; less this 8,000,000bush., the balance available for export was approximately 25,000,000bush. To date of this bulletin it is estimated that 17,000,000bush. has been exported, leaving a balance available for shipping of 8,000,000bush.

VII. Five Months' Oversea Exports (December, 1935, to April, 1936).

The principal countries to which cereals have been exported this season compared with last season is as follows:—*Wheat* (bushels)—United Kingdom, 8,749,045 (8,397,403); China, 655,993 (3,594,793); Japan, 361,160 (3,459,142). *Flour* (tons)—United Kingdom, 14,002 (7,857); Japan—(8,060); Egypt, 4,891 (6,697). *Barley* (bushels)—United Kingdom, 911,288 (362,586); Belgium, 215,258 (1,107,562); New Zealand, 346,390 (264,028); Japan, 33,672 (44,636).

VIII.—Area Intended to be Cropped, 1936-37.

Particulars have been received from farmers in all hundreds of the State as to the areas intended to be sown for the 1936-37 season. These indicate that the following areas were intended to be sown for grain, hay, and fodder:—3,350,000 (3,210,238) acres with wheat, 360,000 (414,419) acres with barley, and 790,000 (692,489) acres with oats—a total for these three cereals of 4,500,000 (4,317,146) acres, or approximately the same as two years ago. The increase in oats is principally in the Western division.

McLAREN FLAT PRUNING COMPETITIONS.

The Annual Pruning Competitions conducted by the McLaren Flat Branch of the Agricultural Bureau were held on 30th May on the properties of Messrs. J. Ingoldby, F. B. Wilson, and R. Nottage. Entries were a little larger than last year in most sections, and the judges stated that the work was of a very high standard.

THE DRAUGHT STALLIONS ACT, 1932.

STALLION PARADES TIME TABLE, 1936.

For the purpose of examining draught stallions for a Government Certificate of Soundness and Approval, parades will be held at each of the following centres on the dates and times specified.

Horses submitted for examination must have had such training that the Examining Veterinary Officer may, with safety, handle their legs; further, the legs of every animal should be in a thoroughly clean condition.

Route No. and Date.	Parade.	Time.
Route No. 1.		
Monday, 6th July	Paskeville Railway Station	9·30 a.m.
" "	Thrington Railway Station	11 a.m.
" "	Kainton Post Office	1·45 p.m.
" "	Arthurton, Arthurton Hotel	2·30 p.m.
" "	Ardrossan, Ardrossan Hotel	3·30 p.m.
Tuesday, 7th July	Maitland Show Grounds	9 a.m.
" "	South Kilkerran Post Office	10·45 a.m.
" "	Port Victoria Post Office	11·30 a.m.
" "	Urania Post Office	12·30 p.m.
" "	Wauraltee Post Office	2·30 p.m.
" "	Curramulka Hotel	3·45 p.m.
Wednesday, 8th July	Minlaton Hotel	9 a.m.
" "	Yorketown, York Hotel	11 a.m.
" "	Edithburgh, Trowbridge Hotel	2 p.m.
" "	Stansbury, Jetty Hotel	3·15 p.m.
" "	Port Vincent Hotel	4 p.m.
Thursday, 9th July	Moonta Railway Yards	10 a.m.
" "	Kadina Show Grounds	11 a.m.
" "	Alford Post Office	1 p.m.
" "	Bews Post Office	2 p.m.
" "	Wokurna Post Office	2·45 p.m.
" "	Bute Railway Yards	3·30 p.m.
Friday, 10th July	Ninnes Post Office	9·30 a.m.
" "	Kulpara Post Office	11 a.m.
" "	Port Wakefield, Rising Sun Hotel	12·30 p.m.
" "	Wild Horse Plains Post Office	1·45 p.m.
" "	Dublin Hotel	2·30 p.m.
" "	Lower Light Post Office	3·15 p.m.
" "	Two Wells Railway Station	3 45 p.m.
Route No 2.		
Monday, 6th July	Mallala Railway Station	9·30 a.m.
" "	Calomba Railway Station	10·30 a.m.
" "	Pinery Post Office	11·30 a.m.
" "	Balaklava Sale Yards, Whitwarta Crossing	1·30 p.m.
" "	Whitwarta Post Office	2·30 p.m
" "	Mount Templeton Post Office	3·15 p.m.
Tuesday, 7th July	Snowtown Railway Yards	9 a.m.
" "	Mundoora Railway Yards	11·15 a.m.
" "	Redhill Railway Yards	1·30 p.m.
" "	Merriton Post Office	3·30 p m.
Wednesday, 8th July	Crystal Brook Show Grounds	9 a.m.
" "	Warnertown Railway Station	11·30 a.m.
" "	Gladstone Railway Yards	1·30 p.m.
" "	Georgetown Railway Station	2 15 p.m.
" "	Gulnare Railway Station	3·15 p.m.
" "	Yacka Railway Station	4 p m
" "	Rochester Post Office	4·45 p.m.
Thursday, 9th July	Brinkworth Railway Station	9 a.m.
" "	Hart Post Office	11 a.m.
" "	Blyth Railway Station	2 p m.
" "	Kybunga Railway Station	3·30 p.m.
Friday, 10th July	Hoyleton Railway Station	10 a.m.
" "	Halbury Railway Station	11·15 a.m.
" "	Owen Railway Station	2·30 p.m.
" "	Stockyard Creek Railway Station	3·15 p.m.
" "	Barabba Post Office	4 p.m.
Route No. 3.		
Monday, 13th July	Freeling Railway Station	9 a.m
" "	Fords Railway Station	10·30 a.m.
" "	Kapunda Railway Yards	11·15 a.m.
" "	Hansborough Railway Station	1 p.m.
" "	Tarnma Post Office	2 p.m.
" "	Eudunda Sale Yards	3 p m.
Tuesday, 14th July	Point Pass Railway Station	9 a.m.
" "	Robertstown Sale Yards	9 45 a.m.
" "	Neale's Flat Post Office	11·45 a.m.
" "	Sutherlands Railway Station	1·30 p.m.
" "	Mount Mary Railway Station	2·15 p.m.
" "	Morgan Railway Station	3·15 p.m.
" "	Annadale (Roadside)	4·45 p.m.

PAPERS READ AT CONFERENCES.

CONFERENCE OF DAIRYING BRANCHES, STRATHALBYN, 21st MAY, 1936.

PRODUCING ONLY CHOICE GRADE.

[C. LUND, Strathalbyn.]

During the past few years dairying in this State has made rapid progress; it has passed from the sideline stage to become one of our main primary industries.

Unfortunately, with the increased quantity of butter made, the quality has failed to keep pace, and we find on comparing the export record of the percentage of choice butter made over a period of years that whilst the total quantity exported has shown a steady advance, the quality has fallen to an alarming extent, and this in the face of an enormous expenditure on modern machinery at the various factories throughout the State. Results obtained appear almost as if the introduction of up-to-date plant for the improvement of our butter has defeated its own end, and that instead of improving the quality of the raw material, *i.e.*, cream, so as to turn out at least 90 per cent. choice butter it has allowed the grade to fall back, principally, I think, because it is considered that any sort of cream can be converted to a choice-grade butter by a factory equipped with the latest appliances.

Certainly the factories of to-day can improve the quality of some cream enough to raise it from second to first grade, but choice butter can only be made from sound, fresh cream that has received proper care from the time the milk is drawn from the cow until the cream is made into butter.

[Papers Read at Conferences.]

Reasons for the Decline in Butter Grade.

These are:—(*a*) Competition for cream supply. (*b*) Distance of transport between the place of production and that of manufacture. As we are only concerned with the production of choice cream, we can start right on the farm. There are three main factors that must be taken into consideration; they are as follows:—(1) The cow. (2) Her food. (3) The dairyman. The cow is really the medium by which we convert the food to milk, so she is all-important. She must be healthy or she cannot perform the job of producing healthy milk. Abnormal milk should not be mixed with the bulk milk to be separated, or the whole of the milk will be contaminated. By abnormal I mean:—(1) The milk from freshly-calved cows known as colostrum or beastings. (2) Milk containing any trace of Mammitis. (3) Milk from stale cows that are being infrequently milked when being dried off. (4) The first half pint of milk drawn from all the quarters of each cow. This latter milk is very low in butterfat—usually from 1 per cent. to 2 per cent.—but it contains almost all the bacteria, and is frequently the cause of "off" flavours in the cream. On the other hand the last pint of milk taken from the cow is very rich in fat, sometimes as much as 12 per cent. to 18 per cent., so it pays to strip right out every time instead of leaving a little for the next time. Beastings milk can be detected by its viscous and yellow appearance; it is very high in albumen content and low in fat; the albumen decomposes readily, giving the cream a very cowy flavour. Mammitis milk can be detected by its watery appearance and the presence of strings of curd; this curd can also be seen on the mesh of the strainer.

The Food.

It is impossible to produce a choice cream from inferior pasture, musty chaff, or decayed silage. Most cows will eat food that other animals will refuse, but they cannot perform miracles and turn this waste into choice milk. In my opinion, years of grazing and overstocking, without feeding and renovating the paddocks by spelling and manuring is one of the causes of the decrease in choice grade butter. Where it is necessary to graze or feed strong-smelling food to the cows, do so just after milking, or take the cows off at least three hours before milking time.

The Milker.

Naturally the person milking should be clean. The flanks, tail, and udder of the cow should be clipped occasionally; this applies more especially in winter when the hair is long and mud is plentiful. The teats and udder should be wiped with a clean, damp cloth before starting to milk. The bail, stool, leg rope, and the bucket should all be free from litter, and the milker's hands washed and dried before starting a fresh cow. Dry milking is to be preferred to wet milking, providing of course that the udder has been wiped over to remove the dirt, &c., that always accumulates.

The introduction of the milking machine has helped the industry a great deal where large number of cows are kept, but unless the machines receive constant and thorough cleaning the results are not always satisfactory, and the cream has a strong machine flavour Milk should not be allowed to stand in the shed after it is drawn from the cow; it should be strained through a fine strainer, preferably one with a gauze pad to remove fine particles. This will help the separator by removing a lot of fine dirt which has a tendency to reduce the capacity of the separator.

Separate through a clean separator, and wash the machine every time it is used. When the milk is passed through the separator we divide it into three portions, namely, skim milk, cream, and slime. The slime is held in the separator bowl; it contains most of the contaminating agencies, and if this is allowed to incubate until the separator is used again it will immediately contaminate the next lot of milk, the cream from which will absorb a stale flavour. It is a mistake to separate direct into a vessel containing previously-separated cream, and so on until the can is full. The warm cream coming from the separator should be run over a cooler, or if no cooler is available, the vessel containing the warm cream should be placed in cold water and stirred to remove the animal heat as quickly as possible; this increases the keeping quality, and helps to drive off feed and other volatile flavours. It is also important that all cool cream on hand should be mixed and stirred occasionally. Cream kept too long in a number of vessels exposed to air and light will oxidise. This is sometimes the cause of a tallowy flavour, especially if the cream is rich in butterfat.

Stirring cream induces more even ripening. The lactic bacteria that promote the ripening of cream occur in clusters or groups, but when stirred they are distributed throughout the can and ripening goes on evenly throughout the mass; stirring also liberates the gases that are constantly given off by the chemical action that takes place.

It is a mistake to keep cream too long; if butter is made on the farm the cream is ripe enough when 24 hours old in summer and 48 hours in winter. If sending to the factory it cannot be too fresh, because excess of acid caused by ripening before being received has to be destroyed before it is pasteurised.

A clean, cool dairy is invaluable for storing cream, but it should be used for no other purpose such as a store for general produce, or the cream will absorb any strong flavour. Use only well-tinned cans free from rust. When cream comes into contact with iron for only a short time a metallic flavour results; this flavour becomes fixed and reduces the grade of the butter. A clean, damp muslin cloth placed over the top of the can in summer will reduce the temperature considerably, and it also prevents dust or insects from entering the cream. A can of cream cannot develop any more butterfat with age. Quite a number of dairymen will not send their cream to the factory until it has thickened up in the belief that it will give a higher test. Certainly new cream on the farm will not churn out as much butter as ripe cream, but this is only because the fat particles in the new cream are not in a condition to unite to form butter, with the result that excessive loss of fat occurs in the buttermilk. It is to the interest of all concerned to manufacture butter from the cream as soon as possible.

DEHORNING DAIRY CATTLE.

[J. Y. HUDD, Adelaide.]

Two Years' Intense Study and Practice.

Two years ago I wrote a paper on the theory of dehorning cattle for dairy purposes, having just previously had my herd dehorned. To-day I can write from a wealth of experience and close observation, and have come to the conclusion that "horned cattle" are to-day costing the dairy farmers and stud dairy breeders of South Australia the loss of a colossal sum in the vicinity of a £100,000 per year. My cattle are hand-fed practically all the year, and I am in a position to keep them and their habits under close observation. During the 10 years previous to 1934 I lost an average of one to two cows per year from Mammitis or supposed Mammitis, and it was always the heavy-producing cows, usually a few weeks after calving. During the last two years, having only poley cows, I have not had one case of udder trouble, and my milk production per cow has increased approximately 20 per cent.

In taking particular notice of the habits of dairy cows over a number of years I have proved it an infallible rule that a cow with horns always tries to horn the rear half of another animal, but with dehorned or poley cows it is just the reverse, they invariably butt behind the front leg. If you take particular notice of a cow that is horn marked you will see that it is either on the flank or the escutcheon. It does not need much imagination to realise what must have happened to the protruding, pliable, and soft udder of a heavy-milking cow before those horns tore a strip of hair and skin from the flank or escutcheon, and invariably the trouble which develops in that udder in a few days is blamed to a chill, instead of the bruise.

In my experience 90 per cent. of so-called Mammitis can be put down to this cause. When you realise the delicate nature of a cow's udder it is quite easy to picture the damage that must take place from a blow such as a cow could deliver with her horns. Amongst dehorned cows there is no fear of one another; they feed together contentedly whether in the open or in stalls, and the cow that has been the boss and the fear of other cows becomes the heaviest producer, because she feeds instead of spending her time worrying other cows. They become much more docile and easier to handle, and will drink contentedly together at the water trough and, what is the greatest asset of all, they are not in fear of one another. One should realise what an impediment the udder of a high-producing cow must be to her when she wants to move quickly. If all our dairy cattle were dehorned I can safely say from my observations that 90 per cent. of the udder troubles would disappear, and production would considerably increase, as would the quality of the milk and cream, because there is no gainsaying the fact that there is too much produce from damaged udders coming into the market to-day.

If every dairyman and stud breeder would dehorn every heifer calf at birth, in a few years we would have an ideal type of dairy animal. The cost is about 3d. to do 50 with a caustic potash pencil. Let me conclude by saying I would never again handle or keep horned cattle.

THE MILK EQUALISATION PLAN.

[J. R. Hewland (Secretary of the Dairymen's Association).]

For some years past the number of companies and firms engaging in the wholesale milk business in Adelaide has been increasing out of proportion to the increasing demands. These companies and firms do not buy from the producers on the same or equal terms, which results in some of them being in a more advantageous position for trading than others. For example, the bigger and more important firms undertake to buy the whole of their suppliers' output throughout the year, while others buy only a quota, which varies according to the season of the year, and leave the balance on the farmers' hands. The balance is separated, and the cream sold to a butter factory. The quota of milk purchased by these smaller firms is just about the amount they can resell on the city market as whole or liquid milk. The firms that buy the whole of a farmer's output throughout the year can only market a proportion of it in the city at the higher whole milk price, and the balance they have to manufacture into butter, cheese, condensed milk, or ice cream, whichever is the most profitable. This reduces the market value of the milk they buy to these firms, particularly in the spring when milk is very plentiful. One of the largest of the dairy produce companies, on an average throughout the year, cannot market in the city more than a third of the milk it buys from the farmer—two-thirds of it has to be manufactured.

It would seem that each year the smaller firms have waited until it is known what the biggest buyer is going to pay for milk, and they have then agreed to offer the same price or a trifle more, which means that they are in a very favourable position, especially as several of these firms buy on gallon measurement and not on the basis of the butterfat content of the milk which determines its quality.

For example, if a farmer's milk contains 4 per cent. of butterfat, and the milk is paid for in accordance with its butterfat value, its price would work out as follows:—

Ten gallons of milk equals about 100lbs. weight. This would yield about 4lbs. of butterfat, which at 1s. per pound would be worth 4s., thus the net butterfat value of the milk would be 4.8d. per gallon; but whole, that is, unseparated milk, was, at the time of the hold-up, being sold to retail vendors for 11d. per gallon, and to milk shops for 1s. per gallon. In order that the farmer might receive a share of this higher price received for whole milk, firms buying on a butterfat basis buy at whatever the value of the butterfat in the milk may be, plus a bonus of an agreed amount per pound of butterfat. This works out as follows for 4 per cent. milk, plus a bonus of 3d. per pound butterfat, which was the basis of payment for 12 months ending 31st January, 1936:—Assuming that the average price of butterfat was 11d. per pound, then 10galls. of 4 per cent. milk on fat values would be worth 4.4d. per gallon, to which would be added 1s. as a bonus, thus bringing up the price to 5.6d. per gallon. As before stated, the bigger firms manufacture from 50 per cent. to 70 per cent. of their supplies, but the smaller firms, which buy only such quantities of milk as they can resell in the city at 11d. and 1s. a gallon (until the hold-up), did not pay any more, or in some cases only a trifle more, to the farmer than 5.6d. per gallon. It will be readily seen that these firms must have made money.

An Equalisation Committee representing the three sections of the industry, viz., producers, wholesale distributors, and retailers, has been established. The Committee has appointed a Chairman and a Secretary. Each wholesale trader furnishes the Secretary fortnightly with a return showing how much milk he has bought and how much he has sold during the fortnight. These returns are summarised, and the exact percentage of city sales of whole or liquid milk ascertained. The wholesale price of milk in the city has been fixed for the time being at 1s. 1d. per gallon, and the percentage just referred to is paid for at this price less handling charges, which for the time being have been agreed upon as 4½d. per gallon.

It is really the butterfat in the milk that is purchased, and the price fixed for the butterfat in the portion of the milk which is sold in Adelaide as whole milk is 1s. 8.57d. per pound, and the percentage just referred to would be paid for at that rate less the agreed upon handling charges amounting to 4½d. per gallon. The balance known as surplus milk is bought at current butterfat prices, plus a small bonus of 1d. per pound of fat. For example, if the milk sold in the city as whole or liquid milk tested 4 per cent. butterfat, the net price per gallon, after deducting the handling charge of 4½d. per gallon would be 8½d. This means that if the percentage sold on the city market proved to be 50, then in the case of a producer supplying 20galls. a day he would be paid 8½d. a gallon for 10galls. If butterfat were worth 1s. per pound and the milk were 4 per cent. milk, the 10galls. surplus would be worth, say, 4.8d. per gallon, and to this a bonus of 1d. per pound butterfat would be added. The farmer would then receive the following:—

	s.	d.
10galls. of whole milk at 8½d.	7	1
10galls. equals 4lbs. of butterfat at 4.8d. per gallon	4	0
Bonus on butterfat, 1d. per pound on 4lbs.	0	4
equal to 6.85d. a gallon.	11	5

It will be seen that the price the farmer obtains depends upon the percentage of supplies sold on the market as whole milk, and the quantity and value of the butterfat in his milk.

An important function of the Committee is to equalise among the wholesale traders. If the average percentage of whole milk sales prove to be 50, then all firms that have sold more than that percentage on the city market have to pay into the equalisation fund the difference between the money they had received for the extra quantity they had so sold and that which they would have received had it been sold at butterfat values.

During the 12 months ending 31st January, 1936, the average price the producer received scarcely amounted to 5½d. or 5¾d. per gallon, which is less than it costs

There are some farmers who do not approve of this plan, as it necessitates their selling all their milk to the buyers if they wish to get the full benefits of the plan. These men say that this leaves them without skim milk to use on the farm for the feeding of calves, pigs, and poultry, which are profitable sidelines. Indeed, pigs may be very profitable when properly managed, and it is contended that it is bad for a district to be almost barred from keeping them owing to all the milk being sold to the milk buyer.

The farmers who hold this opinion say that their milk should be bought on a quota system; each buyer would then buy the quantity of milk he wanted for his city trade, and the balance would be separated by the farmer, who would sell the cream and retain the skim milk for use on his farm. It is said that the skim milk is worth a good deal more money used by the farmer than he is paid for it under the equalisation plan, which is certainly true. If then, he were paid for the quota of milk he sold for city use at the same rate as he is paid for it under the equalisation plan, and was able to retain and use his skim milk in such a way as to make it worth to him, say, 2d. a gallon, then he would be better off under the quota plan than under equalisation.

This is the problem which those farmers supplying milk for the city trade have to solve—at present there is a difference of opinion amongst them, but as legislation is likely to be enacted at an early date, it will be necessary to come to a decision quickly.

ADDENDUM.

EQUALISATION OF MILK BASED ON BUTTERFAT CONTENT.

RETURNS TO COMMITTEE BY WHOLESALE BUYERS.

Total fat purchased, 252lbs.
Total fat sold as milk, 126lbs.
Therefore quota would = 50 per cent. on butterfat basis.
City milk price at 20.57d. per lb. fat.
Surplus milk price at 13d. per lb. fat.

Wholesale Buyer X (High-testing Milk).

Producer.	Lbs. Milk.	Test. %	Lbs. Fat.	Quota.	City Milk Price. d.	Surplus Price. d.	Total. d.
A	1,000	4	40	$^{20}{}_{20}$	411	260	671
B	1,000	4.6	46	$^{23}{}_{23}$	473	299	772
C	1,000	5.2	52	$^{26}{}_{26}$	535	338	873
Total purchase .	3,000 Av. test 4.6		138	$^{69}{}_{69}$	1,419	897	2,316

50 per cent. quota on 138lbs. fat = 69lbs. fat at 20.57d. per lb. = 1,419d.

50 per cent. sales on 4 per cent. basis = 69lbs. fat = 166½galls. at 13d. per gall. = 2164d.

Difference between sale and purchase price = 745d.

745d. on 166½galls. = 4.5d. per gall. handling costs.

Wholesale Buyer Y (Low-testing Milk).

Producer.	Lbs. Milk.	Test. %	Lbs. Fat.	Quota.	City Milk Price. d.	Surplus Price. d.	Total. d.
A	1,000	4	40	$^{20}{}_{20}$	411	260	671
B	1,000	3.8	38	$^{19}{}_{19}$	391	247	638
C	1,000	3.6	36	$^{18}{}_{18}$	370	234	604
Total purchase .	3,000 Av. test 3.8		114	$^{57}{}_{57}$	1,172	741	1,913

50 per cent. quota on 114lbs. fat = 57lbs. fat at 20.57d. per lb. = 1,172d.

50 per cent. sales on 4 per cent. basis = 57lbs. fat = 138galls. at 13d. per gall. = 1794d.

50 per cent. sales on 4 per cent. basis = 57lbs. fat = 138galls. at 13d. per gall. = 1

Difference between sale and purchase price = 622d.

622d. on 138galls. = 4.5d. per gall. handling costs.

ADVISORY BOARD OF AGRICULTURE.

At the invitation of the Council of the Urrbrae Agricultural High School, the monthly meeting of the Advisory Board was held on Wednesday, 27th May, at that Institution. Members were welcomed by Mr. H. C. Hogben, M.P. (Chairman of the Council), who, at the close of the meeting, in company with Mr. A. R. Hilton (Headmaster) and other members of the Council, conducted the visitors on an inspection of the class rooms where students were receiving instruction. Students were afterwards seen at their outdoor work and other practical activities, such as carpentry, tin-smithing, saddlery, &c. Present:—Hon. A. L. McEwin (Chairman), Messrs. J. W. Sandford, P. J. Baily, J. B. Murdoch, S. Shepherd, H. N. Wicks, A. J. A. Koch, F. Coleman, R. H. Martin, Professor A. J. Perkins, and H. C. Pritchard (Secretary). Apologies were received from Dr. A. E. V. Richardson, Messrs. W. J. Spafford and A. M. Dawkins.

Life Membership.—Professor A. J. Perkins. The Hon. Minister intimated that he had approved of the Board's recommendation that Professor Perkins be appointed a life member of the Advisory Board of Agriculture.

Ridley Scholarship.—Mr. A. M. Dawkins was re-elected as a representative of the Advisory Board on the Ridley Memorial Scholarship Committee.

New Branch.—Approval was given to the formation of a Women's Branch at Koolunga with 24 foundation members.

Life Members.—Mr. A. F. Crossman (Warcowie) and Mr. H. Schunke (Wirrilla) were approved as life members of the Agricultural Bureau.

New Members.—The following names were added to the rolls of existing Branches:—Belalie Women's—Mrs. E. J. Harbison, Mrs. M. I. Pyne, Mrs. I. M. Garnett; Butler—G. C. Teakle, A. R. Turner; Georgetown Women's—Mrs. Payne; Green Patch—P. Pope; Greenock—M. Cundy; Ironbank—Chas. Coates, Jnr.; Kybybolite—T. Treliving, S. A. Ward; Maltee—Jas. Ferguson, Owen Talbot; Meadows—L. H. Teague; Monarto South Women's—Miss C. Jordan; Mount Bryan—F. M. Jeffries, H. Hooper; Mount Compass—Allan Hall; Murray Bridge—H. A. Follett; Palabie—Walter Miller, John Miller, Stanley Wilkinson, Sylvester North; Pinnaroo Women's—Mrs. P. Gordon; Mrs. O'Connor, Mrs. Wirth; Rosedale—Don Watt, Gordon Pobke; Scott's Bottom—J. Bauerstock, H. Carlaw; Sheoak Log Women's—Mrs. T. C. Kennedy, Mrs. W. Ahrens; Springton—Jas. H. Trenorden, Allan R. Forrest, Fredk. R. Johnstone, Jas. S. Miller; Taragoro—Ben Crabb; Tarlee—Nelson Kelly; Whitwharta—C. Plueckhahn, R. Plueckhahn; Yundi—A. Shiers, A. R. Hill, G. E. Leacroft; Yurgo—Clifford C. Spencer, Lindsay A. Burton; Yurgo Women's—Miss Irene Hopgood; Echunga Women's—Mrs. F. Waters (name omitted from list of foundation members).

New Branch.—Koolunga Women's—Mrs. T. Cameron, Mrs. W. Sykes, Mrs. E. Fuller, Mrs. E. Butterfield, Mrs. A. Buchanan, Mrs. H. Spencer, Mrs. R. Bently, Mrs. S. LePage, Mrs. F. Pedler, Mrs. S. Perrin, Mrs. A. Bentley, Mrs. Burton, Mrs. A. Whitehorn, Mrs. R. Haeusler, Mrs. D. Cooper, Mrs. A. W. Mueller, Mrs. C. Longmire, Mrs. C. Binford, Mrs. M. Brown, Mrs. H. Jones, Mrs. L. Lange, Mrs. E. Spencer, Miss L. Pedler, and Miss M. Pengilly.

Several items were taken in Committee.

DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO. LIMITED, reported on 1st June, 1936:—

BUTTER.—The recent splendid general rain has altered the whole outlook for the season and dairymen are now jubilant. Fortunately there has been no heavy frosts during the previous dry spell, and although the grasses have wilted somewhat, the rainfall will recuperate the feed besides causing further germination. Production of butter had fallen to about 40 per cent. lower than for the corresponding period last year but from now on the upward trend should be very marked. London values have moved upwards during the last few weeks and at date Australian choicest on spot was selling at 101s. per cwt. In the local markets values have continued steady at:—Choicest creamery fresh butter, in bulk, 1s. 4½d. per lb.; prints and delivery, extra. (This price is for local sale only and, under the Quota System, the equalized price manufacturers will receive will be 1s. 2½d. per lb., on which basis payments to cream suppliers will be calculated.) Separator lines, from 1s. to 1s. 1d. per lb. for choicest; stores, 8d. to 9d. per lb. (These prices are subject to equalization levies.)

CHEESE.—The backwardness of the season in the South-East had its effect on production, and cheese supplies have been short of requirements for a good many weeks past. However, the position will now improve. Western Australian buyers have been purchasing rather heavier quantities than usual and this has shortened the stocks on hand. Values ruling are:—Large and medium, from 9½d. per lb., loaf, from 10d. per lb., at store door, delivery extra; semi-matured and matured, 1s. to 1s. 1d. per lb.

EGGS.—The mild weather just prior to the rain resulted in the supplies of eggs keeping up well. This will probably be checked during the next few weeks but should quantities increase values would tend easier:—Ordinary country eggs, f.a.q., from 1s. per doz. net; selected new laid clean eggs, full-sized, to 1s. 5d. per doz. net.

BACON—A good demand for prime quality, factory cured, breakfast bacon was maintained throughout the month, but hams have continued very slow of sale. Supplies marketed have been sufficient for all requirements and values at present ruling are:—Best quality sides, 10d. per lb.; middles, 10d. to 10½d.; heavy middles, 9d.; rolls, to 8½d.; hams, 11d. to 1s.; cooked, 1s. 2d. to 1s. 2½d. per lb.; lard, bulk, 6d. to 6½d.; prints, 7½d. per lb.

ALMONDS.—Heavy quantities were marketed during April, but prices continued steady with but little fluctuations:—Softshells and Brandis, 8½d. to 9d.; hardshells, 5d. to 5½d.; kernels, 1s. 9½d. to 1s. 10½d. per lb.

HONEY.—Slightly improved turnover occurred during May, but honey is a commodity which is consumed to a greater degree in the cold weather. There are still, however, heavy stocks held by wholesale merchants. Present values are:—Prime quality clear extracted, 2d. to 2½d.; lower grades, 1d. to 2d. per lb.

BEESWAX.—Only light supplies were marketed and much heavier quantities could have been placed at 1s. 2d. to 1s. 2½d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms. A stronger demand set in towards the end of last month and has continued since with prices firmer. This was due to poulterers generally being short of stocks and also some interstate trade influenced the buying. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. 3d. to 4s. 6d.; nice conditioned cockerels, 2s. 8d. to 3s. 1d.; fair conditioned cockerels, 2s. to 2s. 7d.; chickens, lower; heavyweight hens, 2s. 6d. to 3s. 2d.; medium hens, 1s. 8d. to 2s. 3d.; light hens, 1s. 3d. to 1s. 6d.; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. to 3s. 6d.; young Muscovy ducks, 1s. 7d. to 2s. 1d.; ordinary ducks, 1s. to 1s. 9d.; couple of pens of weedy sorts, lower; geese, 2s. 3d. to 3s.; goslings, lower; turkeys, good to prime condition, 8d. to 9½d. per lb. live weight; turkeys, fair condition, 6d. to 7½d. per lb. live weight; turkeys, poor and crooked-breasted, lower; pigeons, 4½d. each.

POTATOES.—New season's, 9s. 6d. per cwt.

ONIONS.—Brown Spanish, 10s. 6d. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of May, 1936, and also the average precipitation for May, and the average annual rainfall.

* No report received during the month of May. R In recess.

If dates do not appear above, Secretaries are requested to advise the General Secretary of details of Branch programmes, or of the regular night of meeting, *e.g.* 3rd Monday in month.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from 1st August, 1934, with the following exceptions:—Life members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

MEN'S BRANCHES.

TREE CULTURE.

[Paper read by Mr. R. Hastings at a meeting of the Allandale East Branch on 1st May, 1936.]

This is a subject which has not received as much attention as it should have done. This has perhaps been caused by use of superphosphate, making it possible to carry more stock. A tendency for greater subdivision of holdings has resulted, leaving some paddocks devoid of any form of shelter or shade. The value and importance of trees on the farm can hardly be stressed enough. Horses and cattle have more chance of getting away from bot and other flies, if there is a plantation where they can shelter. The appearance of plantations of trees on a holding makes it much more valuable. Trees planted on poor land increase its value both by checking drift and by producing something of value, whereas before, its production was practically nil. If only for use of ewes at lambing time the planting of some trees or shrubs is well worth while. Before the actual planting of the trees the site for the plantation should be prepared and securely fenced. The erection of the fence should receive special attention, as all one's labour will probably be in vain if stock are allowed to break through. If the land upon which the plantation is to be grown is infested with rabbits it would be wise to erect netting. About a fortnight before the trees are planted it is advisable to dig the ground to a spade's depth and leave a small hole in the centre. The next thing to consider is the best type of tree to plant. Several proved types of trees in the district are suitable for plantations, namely, pines, cypress, Yate gums, tree-lucerne, some types of ornamental gums, black and Cootamundra wattles, and others.

The pine tree of the *Insignis* type is the most common and is a better type than the Aleppo. These trees are comparatively quick growing; trees planted on the south side of the Memorial Park about seven years ago are now about 12ft. high. These trees when fairly well grown can have the branches or limbs cut, and a good deal of wood is thus provided. An evidence of this was recently provided when Mr. Charles Winterfield lopped his pine limbs and cut them into firewood lengths. Pine trees can also be made into a hedge if required.

Cypress is perhaps more adaptable for hedge growing than for growing as individual trees. These trees start slowly, but later make rapid growth.

In times such as the present, when firewood is becoming scarce, the establishment of a plantation of Yate gums would be an economical proposition, as these trees can be lopped back every few years without doing them harm.

Tree lucerne is an ornamental flowering tree which grows quickly, with a graceful foliage and a mass of flowers in the spring. It makes a good break or shelter but is not a long-living tree. Tree lucerne provides good food for bees, and can be fed to cattle in time of drought.

The growing of ornamental gums is both pleasing to the eye and adds greatly to the appearance of a holding, besides providing useful shade and shelter.

The growing of wattles for a temporary plantation is commendable, as the bark from these trees is commercially valuable after they have served their period of usefulness as shade trees.

Among the native trees the Sheoak is worthy of mention as it has proved a great standby in times of drought, and when young is perhaps the finest shade tree procurable.

It must be remembered when planting trees of any description that they are robbers of soil, and therefore one cannot expect to grow anything close to them. Pick the place and plant them for shade and shelter as well as to beautify the homestead.

TREE PLANTING.

At a meeting of the Pygery Branch held on 5th May there was a good discussion on planting trees for wind breaks and shelter. Members considered that it would be too costly to grow many trees in the Pygery district, as they required constant watering and attention, and few trees other than native species were suitable. The only tree that was not destroyed by stock biting the bark was the native pine. It was more satisfactory to reserve clumps of native pine, black oak, titree and mallee than to plant trees which would not thrive. Trees or shrubs planted for hedges should be well spaced, otherwise they would die during dry spells. It was advisable to plant a few trees each year, provided they were well cared for.

FORESTRY ON THE FARM.

Paper read by Mr. A. T. Cowley at a meeting of the Roberts and Verran Branch on 13th May.—Forestry and farming, as generally understood, have apparently little in common, and indeed seem directly opposed to one another. The most that the average farmer knows about forestry is expressed in a desire to destroy the forest that he may farm upon the one-time forest land, while the forester in turn may regard the farmer as a natural enemy—or perhaps he would rather say an "unnatural" enemy—for his ideas of farming would probably be that it was an industry suited to the plain country, and not to wooded lands.

There may be room for differences of opinion as to whether wooded areas should ever have been cleared for farming. It is a grave mistake on the part of the settler clearing a new scrub block to clear every acre bare of natural timber, whatever kind it may be. Uusually the site selected for a homestead and farm buildings carries some of the best timber on the place. A fair sized patch of this can be left for ornamentation and shelter around the house, farm buildings, and stock yards, allowing room for clearing a large enough space around each for moving about with stock and plant, and around the house particularly, for a garden.

Some argument against this practice may be advanced on the grounds of the danger of fire, and of scrub around, or near the buildings, helping to spread it from one to the other in the case of an outbreak. However, if all dead wood is cleared up for household firewood, and leaves, bark, and inflammable undergrowth, if thick enough to carry a fire, are raked away from around the trees and burned up in the winter or early spring, the timbered belt around the homestead becomes a protection rather than a menace, for a fire will not travel through it. An important thing to remember when laying out the homestead, etc., is that if the natural timber does not offer sufficient protection, suitable trees should be planted in desired positions during the first winter, or as early as possible, otherwise a bleak and windswept patch of barrenness around the homestead may result.

Odd large trees or small clumps of scrub trees should be left in suitable places for the purpose of providing shelter for stock from summer sun and winter winds, and strips for breakwinds in country that is likely to become windswept, or to drift. Where the native timber is unsuitable for the required purpose, trees of a better class suitable to the locality should be planted, and protected from damage by stock or vermin until large and strong enough to stand exposure, and serve the purpose for which they are intended.

Probably only in exceptional cases would it pay a farmer to attempt to plant and grow his own timber for use on the farm, but a "reserve" of a few acres of straight-limbed mallee, or of ti-tree, sheoak, or pine where these exist, enables one to cut out a few rails or posts, or pieces for many purposes for which "round timber" will serve as well as "sawn", and to save a good deal of expense involved where every stick of timber required around the farm has to be purchased, and often much time lost while it is being procured.

In addition to beautification of the homestead and of the farm generally, shelter for human occupants and for stock, and protection of the land from damaging winds, there is the question of protection and shelter for our bird friends to be considered. That large trees around the homestead harbour birds of vermin types must be admitted, but in consideration of the destruction of many species of useful birds which live and nest upon the ground, by foxes, the fact must be faced that a treeless farm will rapidly become a birdless farm. We are becoming more dependent upon the tree-inhabiting birds to do the useful work of insect destruction upon cultivated crops and pastures, and will eventually realise that shelter for our useful birds must be retained or provided.

With whatever kind of timber a farm may be surrounded, it will be a good rule never to destroy a tree until something better can be put in its place. It may be a crop, a building, a roadway, some other essential—or a better tree. The one item which the average farmer is apt to overlook is the better tree.

THE RISE IN THE SHEEP INDUSTRY.

The above was the subject of a paper read by Mr. E. G. McDougall at a meeting up the Upper Wakefield Branch on 5th April.

Origin of Sheep.—The sheep of by-gone ages, said Mr. McDougall, had not the thick, useful wool it bears to-day. Time and the efforts of man had altered it to an amazing degree. People of the earliest civilisations—races of desert nomads which occupied Mediterranean countries long before 10,000 B.C. tended flocks of sheep and goats, moving to fresh pastures as grass became scarce. After thousands of years the art of writing developed, and from the ancient written records of such people it was learned that they were not without sheep. Records unearthed from burial chambers revealed that sheep had an existence in ancient Egypt thousands of years before the birth of Christ. The Egyptians were skilful weavers. Samples of material taken from mummies and examined under a microscope showed that the fineness of the weave surpassed the best workmanship of to-day. However, they had not learned to make cloth from wool, which seemed to indicate that sheep had not acquired wool as it was known at present. Sheep were mentioned throughout Biblical history, but there was no description of their appearance.

Bakewell.—In England until the eighteenth century no effort was made to improve the carcase of the sheep. Sheep were kept chiefly for wool, and their appearance was anything but up to show standard. The old Leicester sheep resembled something between a sheep and a goat. Then came Robert Bakewell. Bakewell had travelled much, and everywhere he had seen the same poor specimens of sheep. With great patience and care in scientific cross-breeding Bakewell produced a new Leicester, a sheep which made good meat, fattened early, and weighed heavily. Improvements in industry, especially in the cotton industry, were a stimulus to improvement in the wheat and sheep industries. As a result of the industrial revolution the population increased and with it the demand for foodstuffs. There also came into being the Smithfield Club where farmers met and discussed scientific breeding and agricultural improvements generally. Owing to the good work done by the Smithfield Club and to the efforts of Bakewell, by the year 1800 sheep had increased in weight threefold.

Sheep in Australia.—When the first shipment of convicts arrived at Port Jackson in January, 1778, under Captain Arthur Philip, the first Governor of New South Wales, Philip brought with him 44 sheep from the Cape Colony. By September of the same year all but one sheep had died, either from eating rank grass or by the attacks of dingoes. In 1793 30 Bengal sheep arrived from Calcutta and a few English sheep from Ireland. The Indian sheep were a poor type, with a covering resembling hair rather than wool. By cross-breeding with the English sheep their progeny were noticeably improved both in frame and wool. The idea then occurred to a certain Captain John MacArthur that if a better type could be imported, wool of a better class might be produced.

MacArthur.—MacArthur is honoured to-day as the father of the Australian wool-growing industry and the founder of Australia's material prosperity. He threw himself with great vigour into the business of farming, but soon came to the conclusion that pastoral pursuits were more suitable to the country, and began to make his experiments in sheep breeding.

MacArthur purchased 3 rams and 5 ewes from a man who had been to the Cape of Good Hope for supplies and who brought back 26 Merinos. He also obtained 5 rams and 1 ewe from the flock of King George III. at Kew. The Merinos, crossed with the Indian sheep already mentioned, formed the beginning of MacArthur's flock. Other breeders, such as William Cox and the Reverend Marsden built up large flocks, but whereas they were anxious to obtain large carcasses, MacArthur strove to secure better wool. In the beginning mutton was more profitable, but eventually wool became the more important.

He submitted samples of his wool to manufacturers in England, who pronounced it as fine a wool as the best Saxon variety. On the recommendations of the Secretary of State and the Privy Council, orders were sent to the Governor of New South Wales to grant MacArthur 5,000 acres of land on which to carry on his good work.

Following the good example set by MacArthur, attention was given to breeding, and the all-round improvement of the sheep. For a time the idea prevailed that a longer wool of coarse fibre would be best, and it brought about a complete change. However, it was soon realised that a mistake had been made and steps were taken to remedy it.

In about 1860 a craze occurred for wrinkly Merinos. Since 1910 however another change has taken place. It was found that wool from the wrinkly variety was not of such even quality. Plain-bodied sheep with larger frames displaced the wrinkly variety, and at the present time the best Merinos were plain-bodied, well clothed with wool of long staple and good quality.

Discovery of Grasslands.—As long as the sheep industry was confined to the coast it could not prosper. The climate was too wet, causing footrot and water-in-the-head. An important step towards the progress of the industry was when MacArthur moved his sheep from Rose Hill (now known as Parramatta) to Camden. Then in 1813 Gregory Blaxland crossed what had formerly been regarded as an impregnable barrier, the Blue Mountains, and the rich grasslands, with the more suitable climate, were discovered.

Pastoral Age.—The years 1830-1850 had often been referred to as the "Pastoral Age." In the days prior to the gold rush wool was king. A population of less than half a million had 16,000,000 sheep, while so little wheat was grown that flour had to be imported. After the gold rush period, about 1860, the sheep industry underwent vast changes. Population had increased, prices had risen, and in many industries, for a time at least, labour was scarce and costly. Open runs with uncertain boundaries gave place to fenced runs with dams and artesian bores. The country could then safely carry larger numbers; the wool became sounder and the fleece, as a whole, of better quality. Stock was improved; and the advent of the railway made transport cheaper and quicker.

The Boom.—From 1870 to 1884 was a boom period, followed by a decline. Wool prices fell, land values were high, and the rabbit pest became serious. Sheep owners soon began to realise that they must somehow cut costs. Shearers' rates were reduced from £1 per hundred to 17s. 6d. per hundred. The immediate result was the formation of the Shearers' Union, and bad feeling developed between employers and employees. Then Mr. Frederick Wolseley invented the sheep shearing machine, and thus brought about a saving in labour. The idea was said to have come to Wolseley as he sat in a dentist's chair, looking gloomily at the drill which would soon be at work in his mouth.

Size of Flocks.—To-day most sheep were in districts between the 10in. and 25in. isohyets, and very few were in districts above the 75° isotherm. Some were raised where the rainfall was less than 10in. In the central districts of Australia saltbush and bluebush formed suitable fodders. The water problem was overcome to a large extent by means of artesian bores. The largest flocks were on the Darling Downs and the Riverina in New South Wales, and even in South Australia. In early years the flocks were, of course, very small, but in 1891 there were 73 owners with over 100,000 sheep; by 1901 the number had been reduced to 12. At the present time there was one large station in the Riverina with over 150,000 sheep, but generally, flocks were on a much smaller scale than formerly.

The following table shows how the industry has developed:—

1807—MacArthur sent 245lbs. wool to England.
1821—Export of wool amounted to 172,880lbs.
1841—Increased to 9,000,000lbs.
Present exports of wool over 500,000,000lbs., valued at nearly £60,000,000.

Wool had played such an important part in the development of the country and brought in so large an income that Australia had been called "The Land of the Golden Fleece." She was the largest wool producer in the world, producing about 17 per cent. of the world's total, and had an average of 100,000,000 sheep. Only 5 per cent. of the wool produced was utilised in Australian factories.

HINTS ON FENCING.

[Paper read by Mr. S. G. Chynoweth, at a meeting of Boor's Plains Branch on 7th May, 1936.]

In days when fencing timber was plentiful posts were usually placed about 10ft. apart, and experience has shown that the most efficient fences are those with panels of that width. However, the increasing scarcity of suitable timber, together with much higher labour costs have in recent years compelled landholders to exercise greater economy in the use of posts, and the panels are now of much greater width; in extreme cases posts are as much as 1 chain apart. In erecting a fence, however, efficiency must be taken into consideration as well as cost, and it is very bad economy to endeavour to save a little on the original cost by reducing the number of posts if the result means higher cost of maintenance or a fence that will not give the desired protection. The loss consequent upon several valuable horses or other stock breaking through a weak fence on to ripe wheat for instance, may be much greater than the saving effected in the erection of the fence. The limit to the width of panels is still a subject of controversy. It is practically agreed, however, that 22ft. is a very suitable width, and unless posts are very expensive, that is the panel which should be adopted. When wide panels are used, it is essential to use droppers. A number of different types of droppers have been placed on the market; the wooden dropper as used by the railways seems to be very efficient, as their fences are models of efficiency.

TIMBER FOR POSTS.

While certain kinds of timbers are undoubtedly the best for fencing, choice is limited by the kinds available in the vicinity of the area to be fenced. The chief points to be considered are strength and resistance to decay, to attacks of white ants and also fire—that is where the concrete post is most valuable. Size is also an important consideration, though this depends on the kind of timber used, and upon the age of the trees from which the posts are cut. As a rule, small trees are sappy, and decay quickly. Suitable sizes for various posts are:—Ordinary, 6ft. 6in. long, 6in. to 8in. in diameter; corner posts, 8ft. 3in. long, 12in. in diameter; straining posts, 7ft. 9in. long, 10in. in diameter; gate posts, 9ft. long, 12in. in diameter. Gate posts should be let in ground 4ft., strainers 3ft., corner posts 3ft. 6in. A quite common defect in the construction of a wire fence is that of placing the strut too near the top of the post, and consequently at too great an angle with the line of fence. The result is that when the wires are strained, the post is pulled out of the ground. In order to prevent this, the strut should be about 22in. from top of post, and not lower than half-way. It is a good plan to put in a post about 6ft. from strainers and strut strainer against this. A strut too short is a failure. It must be a reasonable length.

BARBED WIRE.

The use of barbed wire very largely increases the efficiency of any fence to which it is attached. Objections are sometimes raised to it on account of the injuries occasionally caused by stock, but these injuries are in most cases brought about by misuse. For boundary or ordinary subdivision fences it is very useful, and the likelihood of stock being injured is very remote provided it is kept reasonably well strained. Barbed wire should never be used in yard fences or in fences where horses congregate, such as near stables, as in the fighting and playing which goes on amongst them, there is great danger of the animals being badly torn. Barbed wire is most dangerous when it is allowed to lie around loose, or is allowed to become very slack in the fences. It cannot be condemned, however, merely because a few people are careless in its use.

RAIL FENCES.

Whilst it has been superseded by the wire fence for boundaries and general subdivision work, for some purposes, such as yards, approaches to gates, bridges, &c., the rail fence is still required. Such fences are more easily seen than wire fences, and their appearance indicates that they are a more effective barrier than even barbed wire. Some details regarding them and their construction are therefore likely to be of interest.

Three-rail Fence.—The posts are mortised as follows:—First rail 6in. from top of post, second rail 21in., third 36in.

Two-rail Fence.—Top rail 6in., second 28in.; one or two wires between rails is very effective.

Single-rail Fence.—Top rail 6in. All measurements for mortises being taken from the top of posts.

ERECTING WIRE FENCES.

In putting up a wire fence, supposing the timber is already laid on the ground, the first thing to do is to dig the post holes; and even in connection with such an apparently simple operation as that, a few things are worth remembering. The holes should be from 22in. to 24in. in depth. They should not be made too big, as this involves unnecessary labour both in digging, filling and ramming; besides, the post will not have such a firm grip in the ground. They should be a little more than large enough to receive the post comfortably and leave room for the rammer to work to the bottom of the hole. Dig the full depth straight away. If a little too deep, it is easy to put in some loose earth to make the post the required height. Sight the posts from the centre, and fill in and ram the bottom first 6in. thoroughly. The bottom and near it is the place where ramming is most required; as the top is approached less ramming will do. Place the earth that remains neatly around the post to allow for subsidence. The tools required for post hole sinking are a medium size iron bar with rammer head and chisel point, and a long-handled shovel. This tool should have a round nose and be bent inwards at the sides, so as to form a kind of scoop. Small post holes cannot be dug with wide shovels. Sink post holes if possible when the ground is in good condition, not too wet and not too dry. When boring for wires, bore straight and right through, so as to push out anything that may impede easy threading of the wire. An easy and simple way of running and threading wire through posts is to place the coil on a reel made on the capstan principle; this allows the wire to run off freely and prevents it getting entangled. The wire is then pulled through the posts from one strainer to another, and strained up tight. Strainer posts are the mainstay of a wire fence, and should be of the best timber procurable. Those used at angles should be mortised to receive stays or struts. All posts should have the bark taken off before being put into the ground. No fence is complete without a gate. All gate posts should be separate from the fence posts.

In ordinary wire fences the wires should be placed as follows, measured from the ground:—6in., 12in., 18in., 25in., 34in., 46in., with barb on top. This is for a 4ft. 6in. high fence. For a 3ft. 10in. fence, 6 wires only are needed. It is a good plan when fencing to use a wire standard attached to the ordinary wooden or cement post to run wires through, as it saves a lot of boring, and if the post gets burnt or decays, it will not interfere with wires.

Gate posts should be 9ft. long, placed 4ft. in the ground, and be about 12in. in diameter. Leave gate post above all ordinary posts adjoining gate, as they look better and set gates off to a better advantage. It shows neatness if all posts are sawn off level on the tops.

THE VALUE OF PEAS ON THE FARM.

[Paper read by Mr. E. L. Orchard (District Agricultural Instructor) at a meeting of the Jamestown Branch on 18th May, 1936.]

The cultivation of peas as a farm crop dates back to prehistoric times, there being no lack of evidence that they were utilised as such by the ruling nations of ancient days, and the original parent of the varieties grown to-day still flourishes in a wild state in the Levant. There appears to be every reason to believe that the pea is a native of Southern Europe and the North Coast of Africa. From there it has spread to all parts of the world where climate and soils are favourable, and due to its proven utility has established its worth in the routine cropping of our cultivated lands.

VARIETIES.

After allowing for the claims of some authorities, that all kinds of peas usually found in cropping systems to-day are members of the one species, they are more generally separated into those of Field Peas (*Pisum arvense*) and Garden Peas (*Pisum sativum*), and of these there are two varieties of Field Peas of main importance in South Australia, viz., Early Dun and White Brunswick. The former, on account of the bulky nature of its growth, is more suited for the wetter districts. It is a good cropper, and holds its seeds well after they are ripe, the variety deriving its name from the fact that the greenish-grey at ripening changes to dun colour. Over the lighter rainfall areas of the north, the White Brunswick Pea is giving good returns, though producing a lighter growth for grazing. They are earlier than the Dun, and so often escape the hot winds of early summer, the same earliness often proving their salvation from the attacks of grubs.

THEIR PLACE IN CROPPING SYSTEM.

Attention has been focussed on the crop during recent years because of its value in rotation with wheat, for in all successful systems of rational cropping where bare fallow is not practised, or only availed of occasionally, a leguminous crop is all-important to invigorate the land and add to its store of nitrogen. Up to the present the only legumes we have been able to crop with any degree of economic success in our recognised wheatgrowing districts are Field Peas, and even these are limited for certainty to those localities where the rainfall is not below 17in.

FOR AND AGAINST.

Bearing this in mind, it will be as well just here, to examine the disadvantages along with the advantages accruing from the growing of peas as a regular farm crop. They will not withstand extremes of weather as other cereals do, thriving best under cool moist conditions, and though they can be grown successfully for grazing where the climate is less congenial, suitable weather is essential to ripen grain. The early growth is hardy and not readily affected by frost, whilst relatively warm dry weather does not check them, even although they do not possess the deep-rooting habit of some cereals. At the same time they are very sensitive to really hot weather, and if subject to hot winds during the later growing period soon wilt beyond recovery. Rough weather or frosts when the crop is in flower work the greatest havoc as far as the setting of grain is concerned; however, this disability applies to some extent with all field crops. Harvesting the pea crop presented a difficulty until within recent years, and definitely limited the extension of the area sown; but with the invention and construction of pea harvesting attachments to the regular wheat reaping equipment on the farm, this has been rendered comparatively easy, and a far less costly job, thus permitting of the profitable growth of the crop over a much larger portion of the State, where previously it could not be undertaken. Lastly, one must not overlook the fact that swarms of caterpillars are at times very troublesome. They not only damage the grain crop directly by devouring it but also by their breaking of the pea hulls leading to a greater percentage of split peas in the sample. Undeterred by such discouraging experiences, however, there are many substantial advantages to be secured by the judicious cropping of peas on most farms situated about our surer rainfall lands. As a fodder crop to supplement the natural pastures, there is no crop that is more valuable for stock. Cows and pigs do exceptionally well on it, the feeding worth of a field of peas having been demonstrated over and over again with lambs, dairy cattle, and pigs. No other annual crop will provide such excellent cheap feed at a time when the natural pastures have given out, thus enabling the farmer to market his stock at good prices, rather than dispose of them at low rates as ''stores''. Held back till the grain has ripened, and then grazed is the most satisfactory method of harvesting with livestock, and could be adopted to the great advantage of many more of the mixed farming properties of the middle and upper north. Peas have a relatively short-growing period, but during that time they build up the reserves of nitrogen in the soil, through the action of the bacteria housed in the nodules on the roots of the plant. Hence the reference to peas as a renovating crop, and the determining factor of their position in a rotation, preceding the main cereal, wheat. Investigational work over a period of twenty odd years under peas, has shown the gain of nitrogen per acre to be equal to an annual dressing of at least 2cwts. of nitrate of soda, whilst for restoring organic matter to the light sandy soils of some districts, either through the agency of green manuring, or the droppings of grazed stock, they are invaluable.

SOILS.

Climatic conditions, rather than soils, may be considered of more importance for the successful propagation of peas, the crop doing well in most soils of normal fertility, provided they are well supplied with lime, as peas remove five or six times as much lime from the soil as do the cereals. The texture of the soil, too, has little influence, though it is only natural to expect the best results from well-balanced loams. On rich flats, and soils of volcanic origin, there is a tendency to bulky growth at the expense of the grain yield.

PREPARATION OF LAND AND SOWING.

As peas do not assist in cleaning the land of weeds, thorough preparation of the soil to be sown, with a view to the destruction of weeds, is advisable. Assuming the crop is to be sown on a wheat stubble, early breaking of the land, followed by a harrowing, is necessary to encourage the germination of weeds with the opening rains, when in average seasons a subsequent cultivation should leave the soil in a clean state for the drilling of the peas. Sowing should take place not later than mid-June, in a seedbed of fine tilth, up to a depth of 2in. in the stiffer types of soil, using not less than 60lbs. of seed, with an increase in quantity even up to 2bush. per acre if it is intended to utilise the crop as green manure, or for purposes other than grain production. The lime requirements having been met by the nature of the soil, superphosphate is applied along with the seed at the rate of 90lbs. to 1cwt. per acre or more, according to the proposed destination of the crop. Leaving the drilled field with a rolled surface will facilitate harvesting by reducing damage and wear and tear of the machinery to a minimum, especially on those paddocks whose soil is largely of a gravelly formation.

UTILISING THE CROP.

All of the pea plant is of value as fodder except the roots, and these perform an extremely valuable function in assisting to improve the soil fertility. Peas may be fed to stock as green forage, or in the form of silage or hay. The grain is the most nutritious of all farm seeds, and pea straw is almost equal in value to good oaten hay. The feeding of peas rarely upsets the digestive organs of the animal, though if fed in large amounts to horses there is a remote danger of flatulent colic or even constipation, but on the whole peas are a very safe crop to feed. Pea hay varies in composition according to the stage at which the crop was mown, and generally should be cut for hay when the first pods are full grown but not filled. The effect of rain on pea hay is to dissolve out the soluble carbohydrates, thus reducing its feeding value. Pea silage or mixed peas and oats or wheat make an excellent combination for ensiling. Silage from such a source is very palatable to dairy cattle, being much richer in milk-producing nutrients than that made from cereals. The crushed grain may be fed as a concentrate in conjunction with bran, milkers producing well on a ration of which peas form about one-third of the daily allowance. Pigs are particularly responsive when fed peas, their digestive tract being well adapted to this grain, less than 1 per cent. being found undigested in the excreta. Peas increase the proportion of lean meat, impart a sweet flavour to the bacon, and make for firm and white fat. Good store lambs will gain from 8lbs. to 10lbs. a month, it taking 3lbs. to 4lbs. of peas to give an increase of 1lb., and actually it has been found that a 20bush. crop will fatten about 10 lambs to the acre and produce about 250lbs. of increase. Given plenty of water, stock fattening on peas require very little attention, and the quality of the meat from pea-fed lambs commends it as being sweet and tender, firm in fat and free from rank flavours.

ORGANIC MATTER IN RELATION TO AGRICULTURE.

[Address delivered by R. I. Herriot, B. Ag. Sc., at a meeting of the Balaklava Branch of the Agricultural Bureau on 27th April, 1936.]

The original source of soil organic matter is plant material. The plant whilst living is fed by two agencies—firstly, the soil solution from which it gains the necessary supplies of mineral matter and water; and, secondly, the air which provides carbon dioxide. The carbon dioxide and water later combine, through the agency of sunlight and the green colouring matter in the leaves, to form starch and the woody tissues of the plant. This latter we refer to as organic matter.

If the plant remains uneaten by stock it will eventually either come to lie upon the surface of the ground, and under marshy conditions form peat, or become mixed with the soil, and as a result of bacterial activity form humus. It will be seen, therefore, that the dead plant returns more to the soil that the living plant takes away, and there is no loss in mineral matter whatsoever.

If, on the other hand, the plant is eaten by stock a certain amount of both the mineral constituents and organic matter is absorbed by the animal. The remainder is returned to the soil in the form of urine or faeces. For a growing animal it is estimated that 90 per cent. of the mineral matter and 50 per cent. of the organic matter returns to the soil in this way. Hence, although under grazing, a proportion of each is lost to the soil, the gain in organic matter is still quite appreciable, whilst the loss of mineral matter is relatively small.

Soils which contain organic matter contain a source of energy, and therefore soon become the abode of numerous micro-organisms. These feed upon the organic matter and destroy it, bringing about such processes as nitrogen fixation and nitrification, both of which result in the formation of nitrates. Hence it can be seen that two opposite processes are at work—one tending to bring about an increase, and the other a decrease in the amount of humus present in the soil.

It is of fundamental importance to agricultural lands that there should be at least a balance between the two processes, and that there should always be a reserve of organic matter in the soil. Observation shows that humus has a number of very important effects upon any given soil:—

1. It gives the characteristic dark brown or black colour to fertile soils.
2. It acts like clay in that it tends to stop plant foods from being leached from the soil.
3. In areas containing plenty of lime humus tends to accumulate in surface layers, in acid soils it moves further down.
4. It binds a sandy soil and opens a clay soil. This binding action is dependent upon the presence of lime, as with lime this humus forms a sticky colloidal substance which causes clay particles to "crumb" together.
5. It increases the water-holding capacity of the soil by an amount which may easily reach 3-4 per cent.

"So marked are the physical properties of humus," says Sir John Russell, "that if 15 to 20 per cent. of organic matter is present in a soil the operation of all other factors ceases to count for much, and the distinctions between sand, clay, and loam are obliterated."

Whether or not we get an accumulation of humus will depend upon the relative activity of both sets of factors. In hot, dry, well-drained soils the destructive process predominates. In cold, wet, and poorly aerated soils we invariably get the accumulation of organic matter, as under these conditions the destructive bacteria are much less active.

Wheatgrowing in Australia is definitely dependent upon fallowing, for which many advantages, including the accumulation of nitrates, are claimed. We do, however, hear too much about its advantages and give little consideration to its one great disadvantage. As a result of misuse the advantages have in many areas of this State, including parts of this district, been turned into disadvantages. I am not suggesting that wheat should be sown without fallow in these areas, for in such areas where fallowing has now become unprofitable wheatgrowing under any conditions is unprofitable, and some other use must be sought for the land.

The climate of Southern Australia is characteristically hot and dry throughout a considerable portion of the year. A well-worked fallow under these conditions provides ideal conditions for the working of a soil bacteria. As stated previously these bacteria feed upon soil organic matter to form nitrates, thus depleting the supplies within the soil. Under average climate and soil conditions of South Australia it is claimed that as much as 1 ton per acre of organic matter is lost during each fallowing period.

The necessity for making good this loss should be obvious to all, but during recent years with their hardships many men have adopted the policy of cropping their land to the utmost in the hope of "something turning up." Such a policy of continuous cropping without replenishing the losses, must, of course, lead to failure.

The effect of such farming systems upon the soil will be dependent upon soil type, as the general "make-up" of sandy and clay soils is so different. Sandy soil, as stated previously, requires the presence of fairly large amounts of humus to ensure its perfect physical condition. Unfortunately under a fallowing and cropping system this type of soil is the most severe loser of organic matter. It does not take many years, therefore, for such soils which were previously fertile to be converted into an unfertile mass of loose, incoherent soil particles of very poor water-holding capacity. The sequel to this is drifting, which is now a severe problem in many wheat districts.

With the heaver types of soil the effects of overcropping are not so apparent to the casual observer. They are also slower to develop, but, nevertheless, the policy of fallow cropping cannot be persistenty pursued without disastrous results. Such soils eventually lose their friability or crumb structure, and become impossible soils to work. Draught is considerably increased, and the surface particles "run together" and "cake" even after moderate rains. Seeding under such conditions, then, becomes an even greater gamble than usual.

Thus it has been seen that the policy of persistent fallow cropping must eventually have its detrimental effect even upon the best lands to be found within the wheat belt proper. The problem which now confronts us is: "How best can we overcome this difficulty?" We must, of course, treat the cause and not the effect. Fallowing periods must be fewer and farther between, and we must introduce a means of increasing the amount of organic matter in the soil. The problem, therefore, becomes one of widening the rotation by introducing pasture years, which in turn, of course, means diversification of farming.

One hears it said far too often that such and such a paddock will not grow enough feed to warrant leaving it out. If paddocks in certain areas are going to be left in the hope that some feed will come up, the statement may be more or less justified—mostly less. If it is known that good grass growths are not usual, then something must be sown to ensure that some growth does occur.

The choice of species to sow in normal and poorer wheat districts is definitely limited and would include oats, barley, peas, and Wimmera Rye Grass. Oats and barley—especially the latter—will, of course, grow in practically all wheat districts, whereas Wimmera Rye Grass and Western Australian White Peas will be more suited to selected localities. All four are, however, admirably suited to the Balaklava district, especially the better parts.

Looking at feed from the soil point of view only, it would effect the greatest improvement upon soil fertility if ploughed in as green manure. The economics of such a system is, of course, unsound in view of the figures quoted earlier, and no one under normal circumstances would recommend green manuring to wheat farmers. Farmers do, however, like all other people, very often seek the easiest way out in that they burn off and destroy, from the point of view of organic matter, growths which with a little extra trouble might have been turned into the soil, and therefore rendered useful.

The Necessity for a Systematic Rotation of Crops.—Haphazard methods get no further in agriculture than they do in any other sphere. We know, of course, that the best of systems gives disappointing results at times, but some sort of a system is invariably better than none at all. For the Balaklava district there is a choice of two proved systems, viz., fallow, wheat, pasture, or fallow, wheat, oats or barley, pasture. Either will prove effective in the long run, but the frequency of the pasture years should be particularly noted.

WOLSELEY ANNUAL FALLOW COMPETITION.

[Judged by E. S. ALCOCK (District Agricultural Instructor).]

Details of points awarded to each competitor are given in the following table:—

Name.	Address.	Position.	Compactness of under-layers.	Condition of seedbed.	Condition of mulch.	Suitability of depth.	Freedom from weeds.	Total.
	Max. Points—		25	15	15	20	25	100
E. W. Sharrad (1)	Wolseley	1	21½	12	13	17	23	86½
G. D. Butler	Wolseley	2	21	13	13½	16½	22	86
R. A. Grosser . ..	Wolseley	3	22	13	13	16	21	85
H. K. Ridway . ..	Wolseley	4	20	12	12	14	22	80
E. W. Sharrad (2)	Wolseley	5	19	11	11	14	22	77
A. E. J. Grosser .	Wolseley	6	19	11	11	15	20	76
H. C. M. Pilgrim .	Wolseley	6	20	11	11	14	20	76

1. E. W. **Sharrad**, Wolseley, 50 acres, No. 1.—This entry consisted of red and black loam. Ploughed with mould-board plough 10th July to 22nd August. Cultivated with rigid tine cultivator last week in September, again first week in November. Harrowed 12th November, again on 7th January. Underlayers were fairly well packed together, but were rather open and dry. Seedbed showed some unevenness, especially where tractor wheels had consolidated the land when wet. Mulch was of fair depth, a little rough in places. Very clean and free from weeds. A few missed places were also noticed on headlands.

2. G. D. **Butler**, Wolseley, 50 acres.—A very even piece of grey, self mulching loam. 42 acres were scarified during June with a Gersch scarifier, and the remaining 8 acres were ploughed. The larger area was scarified during August and again in November. The remainder was harrowed in August and again in September, and then scarified in November. Underlayers were rather open and looser than usual. Seedbed fairly regular. Mulch very good; may have been somewhat shallow in places. Some straw was noticed where fire had missed it. A few places missed. Very clean and free from weeds.

3. R. A. **Grosser**, Wolseley, 50 acres.—This entry was situated in a fine paddock of grey land. Ploughed with mould-board plough in August and early September, then harrowed and spring-toothed last week in September and early October then cultipacked. In January harrowed twice. Under layers were well packed down, but were cracking a good deal. Seedbed was in very fair order. Mulch was somewhat shallow with a few pieces missed. A few weeds, paddy melons, and clover were showing. If sheeped, this could have been cleaned of weeds.

WOLSELEY—ALL FALLOW.

This class has also been a regular feature of this Bureau's activities, and this year only three entries were received. Details of points awarded to each one are given below:—

Name.	Address.	Position.	Compactness of underlayers.	Condition of seedbed.	Mulch— Condition and suitbility.	Mulch— Suitability of depth.	Freedom from weeds.	Total.
	Max. Points—		25	15	15	20	25	100
R. A. Grosser . . .	Wolseley	1	22	12	13	16	21	84
E. W. Sharrad . .	Wolseley	2	20	11	12	14½	22	79½
H. C. M. Pilgrim .	Wolseley	3	19	11	11	13	20	74

1. R. A. **Grosser**, Wolseley, 130 acres.—Grey loam, ploughed during August and completed early in September with mould-board plough. Harrowed and spring-toothed end September and first week October. Again spring-toothed early November, then cultipacked. Harrowed in January. Harrowing during January in such a dry season should prove useful. Seedbed was in fairly good order. Mulch somewhat shallow. Some weeds were germinating, and some which sheep could have kept in check. A fine paddock which should grow a good wheat crop and the smaller area is much better worked.

2. E. W. **Sharrad**, Wolseley, 110 acres and 80 acres.—This entry consisted of two paddocks; the larger paddock had probably more grey land than red. Ploughed with mould-board plough during July and August, cultivated during September and November, also harrowed in November and January. Although under-layers were well consolidated in places, they were very dry. Seedbed showed some unevenness. Mulch rough in places, but fair depth. Very clean, free from weeds. The smaller paddock had a greater proportion of red land. This paddock was not ploughed, but scarified twice during October and then spring-toothed in January. Not in the same condition as the earlier worked entries.

3. H. C. M. **Pilgrim**, Wolseley, 150 acres, 170 acres, 140 acres.—The largest area of fallow entered this year; over 400 acres of mostly black land. All worked for the first time during April, two with the Sundercut disc and one with mould-board plough. Then they were all worked practically the same. Scarified in June and August and cultivated during November. For the area being handled, this was a very fine entry which should yield a fine crop of wheat. The under-layers were rather open and loose, and seedbed somewhat irregular. Mulch was shallow in places, and rather rough. The few weeds were Paddy Melons, Cockspur, &c., and a few pieces were missed.

NELSHABY AGRICULTURAL BUREAU.

ANNUAL SEED WHEAT COMPETITION, 1936.

[Judged by E. L. ORCHARD (District Agricultural Instructor).]

(*a*) Weight per bushel.
(*b*) Plumpness and evenness of grain.
(*c*) Freedom from visible admixture.
(*d*) Freedom from bunt, weed seeds, &c.
(*e*) Freedom from injury in harvesting.
(*f*) Freedom from dirt, chaff, straw, &c.

This praiseworthy endeavour on the part of the members of the Nelshaby Branch of the Agricultural Bureau to maintain an improved standard for the seed wheat sown in the district has now been conducted annually for nine seasons.

On this occasion, in keeping with the importance of the year, an extra effort was made to obtain as many entries as possible, as Messrs. J. A. Lyons and R. D. Nicholls, M's.P., had presented a trophy for the entry gaining the highest aggregate of points.

The committee conducting the Competition was therefore gratified to receive a total of nine entries, which entailed the submission of 18 samples in all for judging. These were duly collected by an independent representative, 2lbs. of grain being taken from 5-bag quantities stored in the barn of the individual competitor, sealed and numbered where obtained, and tabled for examination to the following scale of points:—

	Points.
Weight per bushel	25
Plumpness and evenness of grains	15
Freedom from visible admixture	15
Freedom from bunt, weed seeds, &c.	20
Freedom from injury in harvesting	15
Freedom from dirt, chaff, straw, &c.	10
	100

The Competition was as usual divided into two classes—No. 1 requiring two varieties of seed wheat, and No. 2 the champion variety selected from all exhibits. In the former the samples numbered 7 and 8 of Sword and Currawa respectively entered by Mr. L. C. Roberts were awarded a total of 183 points, thus becoming the winner in that class, with Mr. T. Davies (17 and 18), exhibiting Nabawa and Currawa, to gain 182 points, filling second place. The position of Champion Variety is filled by Currawa, which obtained 93.25 points for Mr. L. C. Roberts.

Weight Per Bushel.—This produced a variation from 66¼lbs. down to 60¾lbs., the average of the whole exhibits being practically 63½lbs.—a satisfactory figure when compared with the means of previous years. Nabawa was disappointing in this regard, only one entry of that variety tipping the beam at 63½lbs., the remaining seven of the group of eight varying between that and the lowest weight of 60¾lbs. Currawa weighed consistently well, the five entries of the variety making an average of 65.7lbs., whilst two samples of Ranee were as well above the average as the Waratah and Sword were below it.

Plumpness and Evenness of Grains.—Varietal differences only accounted for a little variation in regard to plumpness, the elongated grains of Nabawa contrasting with the "shotty" Ranee kernels, and the characteristic crosswise crease of the Currawa. Ranee conformed to an evenness only equalled by the Waratah, with Nabawa presenting a percentage of undersized grains in one or two entries.

Freedom from Visible Admixture.—In two or three instances doubt was felt regarding odd grains not complying with those of the variety exhibited, but the majority of the samples gave little cause for comment under this heading.

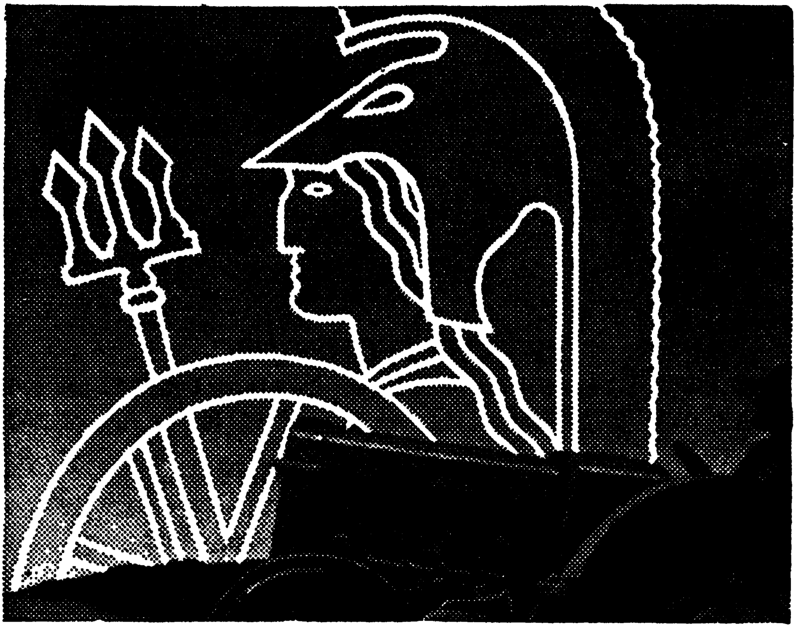
Freedom from Bunt, Weed Seeds, &c.—Grains of barley unfortunately intruded in several of the exhibits, both it and bunt balls being noted in one entry. The question arises as to whether wheat sheltering barley should be classed as grain suitable for sowing. Odd weed seeds of other kinds were found occasionally, but apart from the barley, no great trouble was experienced in this respect.

Freedom from Injury in Harvesting.—Taking the exhibits right through, there was also a pleasing absence of this disability, though now and again the longish soft grains of Nabawa had apparently suffered to a greater extent than the others, whilst one sample of Waratah compared more than favourably with the majority.

Freedom from Dirt, Chaff, Straw, &c.—A sprinkling of chaff was noted in all of the samples, it being the retention of a few glumes only in most instances, an odd node or two in addition appearing in the remainder of the entries. Apart from thistle, exhibits as a whole were quite free from dirt. That the grain was of a uniformly high grade throughout is indicated by an average allotment of almost 88 points per sample, thus demonstrating the essentially useful work, in one direction alone, undertaken by the Nelshaby Branch members.

KILLING AND CURING A PIG FOR HOUSEHOLD USE.

In the course of a paper read at a meeting of the Whitwarta Branch held on 18th May Mr. W. H. Hoepner stated:—"On most farms each year at least one or two pigs are kept for killing to supply ham, bacon, and lard for household use. When these three products are required the Tamworth-Berkshire cross is preferable, as this type of pig will fulfil those requirements better than other types with a less amount of feed. Where a large pig is desired for killing, a weaner or slip is best obtained for killing the following winter. It should then weigh about 300lbs. If the ham and bacon is to be used immediately after curing a smaller pig is better, but when the meat is to be kept for some time it will be found that larger hams and bacon retain a much better flavour. The streaky bacon which is mostly desired is obtained to a certain degree by the feeding method. This is done by keeping the pig in store condition to within three months of killing, then feeding grain to the greatest extent. No matter how fat the pig appears it will give bacon with a fair amount of streak. Killing of the pig is best done during the winter months, as otherwise the thickness of the sides and larger hams will prevent it from cooling and setting thoroughly during the night, which is essential if the hams and bacon are to be kept for some months. Sticking the pig so that it bleeds thoroughly is also essential if the curing is to be successful. To pierce the throat so that it bleeds freely, strike with the blade of the knife entering in a direct line for the tail. The scalding so that the hair comes away freely is best done in a sheltered position away from cold winds. Do not have the water too hot. If the hair does not come away freely through the water not being hot enough it can be made hotter. If the water is applied too hot the flesh will be scalded. Where a person has to do the scalding alone, pour the water on a section of the carcass, scrape this clean, and continue with another section. If more hands are available, dipping the whole pig in a tub or vat is quite satisfactory. After scraping, the pig is suspended on the gallows, and the head taken off. To do this cut right around through the flesh to the bone about 2in. behind the ears. A short twist will then dislodge the head from the body. After taking out the intestines, the fat which is to be rendered down for lard can be taken out cleanly to the last particle. If one is careful to get it loose at the bottom by inserting the thumb between the thin skin which covers the fat and the ribs, and then pull upwards, the whole of the fat will come away from one side in one piece. If the intention is to roll the bacon after curing and the pig is a large one, instead of cutting straight down the centre of the back cut down through the flesh from the back of the pig about 1in. from each side of the centre of the back from top to bottom; then cut through the flesh to where the ribs join the backbone and saw these bones through close to the backbone. The morning after the pig has been killed the meat should be cut up as required, the



Use a BRITISH tractor fuel of PROVED performance

Britain buys Australia's primary products. Bear that in mind when you buy your tractor fuel. And as "C.O.R" Power Kerosene is British-Australian *and* gives more acres per gallon, isn't it the logical choice of the Australian tractor owner?

EGGS—July to September.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2oz., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

sides being cut out for the bacon, and the ribs taken out if bacon is to be rolled later. The hams should be cut to shape, and the fore-parts cut into smaller sections for curing. The two methods of curing are by dry salting and by curing in liquid brine. Curing in brine is the most satisfactory method of the two, and is done as follows:—The day on which the cutting up is done all the meat for curing should be rubbed sparingly with dry salt prior to putting it in the cask or vat in which the curing is to be done. The brine which is to be put over the meat is made from the following ingredients:—18lbs. salt, 10ozs. saltpetre, 1½lbs. white sugar, 12galls. water. Bring this mixture to the boil, then when thoroughly cold pour it over the meat. The smaller pieces, which are usually used as pickled pork, will be cured within a week. If the pig was 300lbs. in weight the bacon should be left in the brine a fortnight at least, and the hams a month. A point which assists in the successful curing of large hams and bacon is to select some shaded position where the cask or vat containing the meat can be stood so that a continual circulation of fresh air surrounds it. After the curing period, if the bacons are to be kept some time they should be rolled on the day they are taken out of the brine. They do not then become so dry and hard. The process of smoking the bacon and ham can be done in any small enclosure, as long as the smoke can circulate freely around them, continuing until the outside appearance is of a golden colour. Precautions must be taken when doing the smoking to ensure there is no heat. Good results are obtained by putting a few red coals in a dish and covering them with damp sawdust.''

HINTS ON THE FARM.

At a meeting of the Wasleys Branch, held on 7th May, Mr. V. W. Day described various articles which could be made on the farm. Swings for a horse team could be made from piping and old thresher drive chains by riveting or sweating steel ends into 1½in. or 2in. piping, using 21 links of chain instead of iron rods, and placing the hitch-up hook in the centre link. Swings should be wide enough to prevent horses' sides from being chafed. Single swings should be about 38in. to 40in. wide, allowing 16in. per horse for spreaders used in large breast teams. Couplings should be not less than 27in. long to allow the team to be turned without trampling on and unnecessarily jostling one another. If the chains or traces used were at least 9ft. long the swings would not hit the horses' heels. Tying back fast horses was unnecessary. They should be placed in different positions in the team until their proper place was found, although it was preferable for a horse to be trained to work anywhere in the team. If, however, a horse had to be held back the use of a double eccentric bit in the bridle would hold the horse, no matter in which direction he pulled. Bridles could be repaired quite simply by riveting straps of hoop-iron up the sides; the blinders could also be kept in position by riveting a piece in a vertical position just behind the bulge. The forehead strap should be left free at one side to allow to-and-fro movement for the choke strap. A strap that was too tight caused the horse's head to become sore. Reins or narrow straps could be mended strongly by cutting the ends straight across, placing two pieces of fine galvanized wire through awl holes and hammering them down firm and snug. Such a join would not give way under a straight pull of considerable power. Elaborate stabling was unnecessary, stables being useful only for the convenience of catching and harnessing. During fine weather horses preferred to feed in the open. An occasional syringing of phenyl and water on the legs of animals would rid them of leg-itch. For cutting the hooves of young horses an instrument made similar in form to a plough scraper and heated like a searing iron was more effective than mallet and chisel. Mr. Day's method of rearing a foal was to shut up the foal, when a few weeks old, in a yard close to the stable. The yard should have rails at the front, which would permit the foal to put its head through and suck the mare. In the course of time both foal and mare became accustomed to being apart at feeding time, and after a time forgot each other. The foal could be kept in the yard for 8 or 9 months, and should be taught to be tied up with a halter. When green feed was plentiful the foal could be turned out into the paddock with other horses. Oaten hay of good quality was preferable for feeding horses. The quality of the hay depended on the manner in which it was cut and stooked. If the hay was heavy and green it should be left to dry for a couple of days prior to being stooked, but very light hay should be stooked as soon as possible after mowing. During rush periods the midday feed should consist of 1½ dippers of pure oats.

SUNDRY HINTS.

Clothes-props could be made from galvanized pipe, with a slot cut in one end, placed in the clothes line, and a ferrule screwed on to keep the prop in place. *Holes in Troughs* could be repaired by means of a gutter bolt and a piece of good leather or tin. *Rolling Barbed Wire.*—A forked stick, long eonugh to enable the operator to stand erect and wind the wire, could be put away with the wire and used again when it had to be unrolled. *Cleaning Stars of Drills.*—Stars should be placed in hot water. If waste engine oil was smeared on them before they were replaced they would be more easily cleaned next time. *Bedding for Pig Sties.*—Dry horse manure; also useful for keeping animals clean if put on decks of motor trucks. *To Stop Pigs Rooting.*—Drift sand placed on floors of pig-sties; would also prevent rats from burrowing in floors.

DOES IT PAY TO BREED OUR HORSES?

The above was the subject of two papers read at a meeting of the Appila Yarrowie Branch on 1st May. Mr. E. B. Wurst stated that it paid the farmer to breed his own stock because he knew just what he was getting, whereas if horses had to be purchased he had to take the word of the seller. It was cheaper to breed high class stock than to buy, because good horses had become scarce. A good horse would cost approximately £40, making the cost of a 12 horse team £480. In the case of a farmer breeding his own stock, 6 mares could be bought for £240, and stallion fees would cost £4 per mare. If all mares foaled each year, at the end of four years the breeder would have 30 horses, comprising one 12 horse team, six three-year olds, six two-year olds and six yearlings. The stallion fees would amount to £96, the total cost of stock being £336, not including expenses of feeding, housing, &c. Many farmers who kept horses and did not breed from them had sold their horses and bought tractors, because it did not pay them to keep horses without breeding from them. Many such farmers had recently gone back to the use of horses, as they realised that it paid to breed their own stock and they could not breed tractors. It might be said that the farmer who bred his own stock could not work his mares all the year round. However, the man who bred horses usually had a few horses to spare and could at least spell the mares for a few days after foaling. It might also be said that there was a risk of losing mares in foal, but the risk from that source was no greater than from injury, sickness, etc. In many years of breeding the writer had not lost a single mare in foal, although six had died from disease, broken legs, etc.

In his paper Mr. L. B. Klemm referred to the considerable expense of purchasing a good type of stallion, which was often beyond the means of the average farmer. Feeding the stallion entailed a great deal of work and attention. Working the stallion in the team meant a lot of trouble and constant watchfulness. For the price paid for a stallion one could purchase three or four working horses. In breeding foals one had to give the mare a good deal of attention, and when the foal was born it must be cared for and fed for 2 years before it could be broken in to work. Travelling a stallion was not profitable. It was necessary to insure the stallion and man and pay the man a good wage; by the end of the travelling season the owner would be out of pocket.

CARE OF LIVESTOCK.

In the course of a paper read at a meeting of the Warramboo Branch on 8th May, Mr. O. J. Murphy stated:—"Clearing sales have indicated in numerous cases that the value of horses on many farms is almost half the total value of stock and plant, excluding sheep. From a business point of view then, if from no other, the horse is well worth caring for, and the most profitable horse is the one which works well, feeds well, and requires little or no veterinary attention. A good supply of drinking water is the first essential. The horse should always have access to water before feed is given to it. This is a matter of first rate importance. In the pioneering days of the West Coast, when wheat was carted long distances by horse teams, and water supplies were few, teamsters were frequently forced to feed their horses at the terminal points while their wagons were being unloaded, and to water the teams afterwards. This practice so seriously affected many of the animals that supplies of carbonate of soda invariably formed part of the equipment of the long distance carters. Feeding should be done at regular intervals—four times a day when the horse is working hard. Two small feeds are better than one big one. Feed on chaff three times a day and give long hay at night. If cocky chaff is used it is advisable to feed in boxes or mangers which will allow the dust to escape. It is very difficult to obtain cocky chaff free from dust in mallee areas. Regular work and regular feeding practically throughout the year will result in fewer ailments than heavy work over a few weeks followed by long spells of idleness. The word 'condition' is often misapplied, and is perhaps better understood by trainers of race horses than by farmers. The horse which has fattened quickly during a spell of idleness on greenfeed looks well and is said to be in good condition, but it is a dangerous condition for hard work. A discriminating owner will work his horses with the greatest care after a spell on good paddock feed. Although the horse is then fresh and lively, and perhaps a little difficult to catch, it is not wise to knock him out with long days in the cultivator or plough. Stop the teams once or twice each round, and work comparatively short periods for a week or so. By so doing you will avoid sore shoulders, and possibly digestion upsets. A soft sweating horse with a well fitting collar is probably more likely to get a sore shoulder than a hardened horse wearing a collar two sizes too big. If the so-called condition which the horse has put on during his spell is worked off gradually, you will obtain that real condition which will allow you to work your team steadily over long hours. The in-foal mare may be handled in the same way as the gelding. Steady work right up to foaling time is more beneficial than otherwise. Experience has proved that foaling risks are extremely light if the mare is kept at work. The time to spell the mare is when the foal is born. Many stock troubles are due to deficiency in diet, which usually results from a deficiency in the soil. That deficiency is phosphoric acid, and is supplied by the application of superphosphates. Other elements such as lime are present in ample quantities. It is obvious that in new mallee areas such as ours, the deficiency noted can only be made up after many applications of superphosphates over a number of years, and while that deficiency exists to a marked degree it will be found necessary to give to stock that which is lacking in their daily feed. This can be done by providing licks for horses, and by feeding sterilised bone meal to cattle. The disease known as "dry bible" can be prevented if suitable licks are provided for cattle. If licks are not accessible to stock at all times, they should at least be provided when the cattle are seen picking up bones or other rubbish and when horses are seen chewing the bark from trees."

CARE OF FARM HARNESS.

At a meeting of the Koppio Branch held on 6th May, Mr. F. Gardner read a paper "Care of **Farm Harness.**"

Mr. Gardner stated:—"Harness should always be kept out of the weather when not in use, and it is a good plan to have a separate shed for the harness instead of hanging it on a nail in the stable. Have a peg for each set of collar, hames, and winkers, and each horse's harness can then be kept to itself; workers and buggy harness can have its own place.

A few pegs should be provided for leading harness and saddles. For oiling harness get a 12-gallon oil drum and cut round the ends half way and then down the middle along the seam, and then fold back the piece so as to form a drain when put up alongside a wall under a peg.

Into the drum put all the winkers, placing them as closely as possible, and then pour over them sufficient good leather oil to half cover them. With a tin or ladle dip oil from the sides of the winkers and pour it several times over the ones not covered. After an hour or two change the position of the winkers so that the top ones will be on the bottom in the oil. After about half a day the winkers can be taken out and drained by hanging them on the peg above the drum and the oil runs back into the drum, which is then ready for hame straps, breeching straps, belly bands, spiders, reins, which can be folded into a short space. While they are soaking get to work with a brush on the collars, which cannot be soaked.

Give each collar a good coating of oil with the brush—as much as will stop on—and hang it on its peg until all have been done, and then start over again, as by that time the first one will be ready for another coat. This should be continued until the leather will not absorb any more oil.

Do the same with the saddles, until you cannot get any more oil into them, and then hang them in their places.

During the oiling process one has a good chance of finding any places that want stitching or riveting. If a farmer keeps a packet of assorted copper rivets, or better still, a ball of hemp, some wax, a couple of needles, and an awl, he can keep the harness in reasonable repair, and often save it from going to pieces to such an extent that it requires to be sent to a saddler.

Rivets should not be used for reins, as they are apt to catch on hame rings or other parts of the harness or implements, and when pulled will come off suddenly and jerk the horses' mouths.

After going over the winkers, reins, hame straps, and spiders, look to the collars. If stitching is required it came be done with a piece of good sewing twine, either soaped or waxed. If a collar is not too bad it can be made to last a considerable time.

A collar that gives a horse a sore shoulder should be marked and a slit cut in the check about an inch long, a bit of horse hair being worked around the patch with a stilletto or fine punch, and filled around the spot to raise it off the sore. The sore will then generally heal in short time.

Of various leather oils tried, the best is Shell compound neatsfoot. It is very penetrating and lasting, and is cleaner than most others. Three gallons of this oil will oil the harness of a 10-horse team twice a year."

During the discussion, Mr. Low said that he has a tender-skinned mare, and by cutting and moving the stuffing in the collar he had managed to cure her shoulders, but the collar was not of much value. He used equal parts of blacklead, boracic, and Coachalene to rub on any galls or light collar sores. He preferred Vacuum leather oil, as it left no surface oil to dirty the hands. Mr. Cooper found that a sheepskin pelt made a good false collar (skin side to horse) when collars became too large. He had used a wood collar with advantage to his horses. For a horse that was subject to sore shoulders he had bought a new leather-lined collar, soaked it in water for 2 days, fitted it while wet, and worked the horse. The collar pulled to the shape of the horse's shoulders, and the horse had no more sores. Mr. Wait disliked working horses with sore shoulders, but did not favour cutting collars, as it let dirt in. He eased the stuffing away from places where there were tender spots with the aid of a long awl. He did not like harness spongy with oil. Mr. M. T. Gardner's practice was to buy 4 gallons of Shell Compound oil each year and pour it into a 12gall. drum from which one end had been cut out. He dipped the harness into the oil and removed it immediately, placing it on a sheet of iron which allowed the surplus oil to drain back into the drum. He had in use 3 pairs of winkers 30 years old which had been regularly oiled. After being used on harness the compound neatsfoot oil was useful as a rust remover, and for oiling iron work on machinery and in the blacksmith shop. He preferred to oil harness on very hot days, and to do the job in a shed. Under those conditions it did not get too much oil. Mr. F. Gardner exhibited several collars with stuffing adjusted to ease sore shoulders, and also several pairs of winkers which he had bought cheaply and restored to softness by oiling.

DRILL OR COMBINE FOR SEEDING?

Papers dealing with the merits of the drill and combine as seeding implements were read at a meeting of the Morchard Branch on 8th May. Mr. C. Schulz stated that the drill was a surer implement than the combine, and gave a more even seedbed. The drill enabled the farmer to sow the seed at any depth, and the more even sowing resulted in quicker and more even germination. The drill destroyed more weed growth and gave the soil an extra tillage. The combine was admittedly cheaper to use, but wheat sown with a drill would yield up to 2bush. per acre more than with a combine. That fact had been proved time and again, nine out of 10 crop competitions having been won with crops sown with the drill. The land must be well cultivated before the drill was used. Most farmers made a mistake in harrowing before cultivating. Harrowing only disturbed the top soil, leaving the underlayers lose and lumpy. Cultivating before harrowing gave a better seedbed. If the latter practice were adopted, together with the use of the drill, farmers would grow more wheat than with the use of the combine. The drill left a small farrow which caught any moisture falling directly over the seed, whereas the combine left a small crown.

In his paper, Mr. C. Halliday stated that many looked upon the combine as the ideal machine for seeding. It was certainly a great help to a man who was seeding on his own, but it was not necessarily the best implement for the work. It was doubtful if the combine was a success in destroying weeds. Well rooted weeds were only hoed up and left to grow better than before. Some farmers stated that if rain fell overnight land that had been combined was seeded and ready to germinate, but the writer questioned whether such grain was sown to the best advantage. A big fault with the combine was that it would continually sow too deeply in dry ground. Deep sowing resulted in thin unhealthy plants which would never give a good return. Much of the drift in dry districts could be attributed to the use of the combine, which worked only the to soil, allowing it to blow away in the wind. In cases of dry seeding the combine had yet to produce as good a crop as the drill. The combine was ideal for levelling a paddock, if worked across the old workings.

FISHING ON THE RIVER MURRAY.

In a paper read before the Ramco Branch on May 4th, Mr. A. Modystach stated:—Each fisherman pays a licence for a certain stretch of the river and he is the only one allowed to use nets and cross lines in that portion. Two pegs might be seen about 10ft. apart, standing up in the water near the bank and further up stream another peg. This would be a "drum net" as it is called. It is made of string and is set facing down-stream, the two pegs holding the wings apart and the single peg holding the closed end. A cross line is a line with numerous hooks at certain distances apart laid across the river. The chief fish caught are the Murray cod, callop and bream. It is said that cod grows 1lb. per year but if so some of the big fish caught must be very old.

Fishing is not what it was before the locks were built in the river, according to most of the men who were fishing in those days. However, the locks have steadied the current considerably, while the river is kept at a higher level. The reeds and rushes are more plentiful and therefore the river is more suitable for the breeding of young fish, because in the reeds they are fairly safe from pelicans, cranes, shags and other fish-eating birds. With still water the feed is more plentiful, the fish are fat and do not swim far for it and thus are harder to catch and seem more scarce.

Very little is known as to whether fish travel far. Some fishermen say they are continually travelling up-stream. If this is true, in a short time most of the fish would be below one lock or another and few in other parts of the river. When the Fishing Commission was in the district they suggested to the fishermen that all small, undersized fish caught be kept and put in cages. When next the Inspector came up such fish were to be collected and freed in different places after being marked with a smal metal disc stating the place and date of liberation. When caught later the fisherman was to notify the Inspector where it was liberated and where caught. By this means something definite would be known as to their habits.

HINTS ON FALLOWING.

Paper read by Mr. T. Peake at a meeting of the Monarto South Branch held on 16th May, 1936:—July is a good time to commence fallowing. All farmers by this time should have the necessary implements and harness in thorough working order to save any delays. It is also necessary to see that the horses do not get down in condition during seeding time, as this will cause a considerable delay, especially if the job is a long one. A medium weight mouldboard plough with a P. shear is a most suitable plough. It makes a clean cut, and lasts longer than most other steel shears. Heavy soil should be fallowed at a depth of not more than 3in. Special care must be taken not to interfere with the subsoil, especially if the clay is shallow. No good results can be expected unless this care is taken. Light or sandy soil should not be fallowed more than 2in. to 2½in. deep, as this class of soil will not need as much working. The heavy land should be allowed to set for some weeks before being disturbed, and then harrowed after a rain to break down any clods and level the soil if necessary. Cultivating should then be done at intervals after a rain of about 35 points in order to keep the soil free of weeds and to retain further moisture.

SUMMARY OF REPORTS RECEIVED.

Branch.	Date of Meeting.	Attendance.	Subject.	Secretary.
		SOUTH-EASTERN DISTRICT.

WOMEN'S BRANCHES.

"Women's Branches of the Agricultural Bureau continue to gain in popularity amongst country women," reported Mr. F. C. Richards (Asst. Secretary of the Agricultural Bureau) when he opened a Women's Branch at Koolunga on 6th May, bringing the total number of Branches to 62 with the fine total membership of 1,439. The Koolunga Branch elected the following officers:—President—Mrs. S. Perrin; Vice-President—Mrs. E. D. Whitehorn; Secretary and Treasurer—Mrs. A. Buchanan; Members of the Committee—Mrs. W. Sykes, Mrs. F. Pedler. The following ladies were enrolled as Foundation Members:—Mesdames T. Cameron, W. Sykes, E. Fuller, E. Butterfield, A. Buchanan, H. Spencer, R. Bentley, S. LePage, F. Pedler, S. Perrin, A. Bentley, — Button, A. Whitehorn, R. Hauesler, D. Cooper, A. W. Mueller, C. Longmire, C. Binford, M. Brown, H. Jones, L. Lange, E. Spencer, Misses L. Pedler and M. Pengilly. It was decided that meetings of the Branch should be held on the third Thursday of each month.

GARDENING FOR PLEASURE.

[Mrs. B. D. E. Bottrill, Bordertown.]

One of the most pleasant hobbies and one which will give most interesting results, whether it be flowers or vegetables, is gardening.

Lawns.

Practically everyone who has their own home and plans their own garden is undecided as to what kind of lawn to put in. For a croquet or tennis lawn I recommend Couch Grass. This grass stands up to heavy use, and with plenty of watering, mowing, and rolling makes an ideal lawn. Seed should be sown at the rate of 1oz. to the square yard. Sown with bone super in early August it will make good headway the first summer. For a lawn which is not expected to stand up to hard usage I suggest Buffalo Grass. This should be planted in rows 9in. apart, and the roots 6in. apart in the rows. A Buffalo lawn when established requires top dressing each year with a dressing of bone super first, then over that fine loam. This should be done towards the end of July or early August. For a lawn to beautify the surroundings I recommend Chewing's Fescue and Kentucky Blue Grasses. The mixture is 1lb. Kentucky Blue and 2lbs. Chewing's Fescue to be sown 1oz. to the square yard. From early August this grass mixture will give an evergreen lawn of a rich, deep green, and once established will be found most effective in the flower garden.

Shrubs.

The selection of shrubs is important in planning a new garden, as the future effect must be taken into consideration. By all means plant a few shrubs; they not only relieve the flower garden from flatness, but are ornamental and serve the purpose of shelter for both the residence and the flower beds. Many gardening enthusiasts prefer flowering shrubs, particularly of an evergreen type, in preference to deciduous shrubs—those that shed their foliage in autumn. The following are worth a place in the garden of the average class of soil:—

Shrub.	Height.	Colour of Flower.
Abelia,	5ft.,	pale pink.
Plumbago,	8ft.,	blue.
Tecoma Capensis,	8ft.,	red.
Tecoma Lindleyana,	6ft.,	lilac.
Virgilia Capensis,	30ft.,	purple and white.
Buddlea Veitchi,	8ft.,	purple.
Nerium (Oleander),	10ft.,	red, pink or white.
Sparmannia.	10ft.,	double white.
Laurustinus,	10ft.,	white.
Myrtus (Myrtle),	10ft.,	creamy white.
Hisbiscus Lamberti,	5ft.,	scarlet.
Podalyria.	6ft..	pink.
Cassia,	6ft.,	yellow.
Pollalyria,	6ft.,	pink.
Euonymus Japonica,	10ft.,	variegated foliage.
Pittosporum variegata,	10ft.,	variegated foliage.
Genista fragrans,	5ft.,	yellow.

The above list of shrubs can be depended upon to give good results in the usual class of soil. One shrub which should have a place in every garden is the Geraldton Wax plant. This plant requires no rich soil or cultivation, prefers a sandy loam, and very little water. In fact many who have tried it have killed it with kindness—too much water and manuring. It prefers to be left undisturbed once it has been established in its new surroundings.

Hedges.

What is the best hedge to plant? Undoubtedly the best is *Cupressus Lambertiana* for all classes of soil. This is close growing, evergreen, and stands a good deal of trimming. Once the variety is established little or no watering is required during summer. Some prefer *Coprosma* as a hedge, but unless this receives plenty of water during summer it will certainly not give results expected. A very pretty, compact hedge may be had by planting Plumbago (blue) or *Tecoma Capensis* (red). Both these varieties—apart from bright flowers—are evergreen, and will stand a good deal of trimming. For a hedge of, say, 5ft., Golden Privet is recommended. This is very compact, and with plenty of trimming makes an ideal hedge. For an ordinary windbreak I have seen *Spartium junceum* (Yellow Broom) put to very good use. With its dark-green foliage and bright yellow flowers it is very effective, but is inclined to become "woody" unless cut back occasionally.

Annuals.

It would require many pages to deal with all the annuals known to the seedsman, but one of the most popular is the nice variety of Stocks. These prefer a light soil if possible; they also flourish on new ground, but on no account should manure be dug in where Stocks are to be planted. This tends to cause "collar rot"; the plants may look well for a while, then suddenly they droop, turn yellow, and the only thing to do is pull them out. This is the result of too much manure; this will also occur to Antirrhinums (Snapdragons).

Another annual very popular is Nemesia; the shades are pink, red, orange, yellow, &c. A bed of these make a splendid display.

Godetia Tall Double Mixed are worthy of space, are splendid for cutting, and require sunshine and little water.

Viscaria (blue) is easy to grow, and a bed or border of this with its lavender-blue flowers will make a good display.

Wallflower Double Annual Mixed if planted in autumn, flower in spring, and at the end of summer may be cut right back; they will then flower again in winter.

Antirrhinums are favourites with most people; such a wonderful range of colour may be had nowadays, although an annual Antirrhinum gives a wonderful show of flowers the second season if cut hard back at the end of summer.

Larkspurs Double Mixed.—This is the "Annual Delphinium." They are excellent for cutting, and give a wonderful show of bloom—especially the variety known as "La France," a salmon pink—but the mixed varieties of the Double Larkspur are well worth growing.

Phlox.—These bright annuals will give excellent results if planted out in late autumn. They will then flower from the first sign of spring until late summer.

Zinnias.—Three outstanding varieties of this showy summer annual are Giant Dahlia Flowered, Giants of California, and "Fantasy." The last mentioned is the latest introduction. There is a splendid range of colours, and the flowers themselves are not unlike a Cactus Dahlia, the petals being curled and twisted. Well worth growing.

Cinerarias are becoming very popular, both as a shadehouse plant and also for bedding. Wherever it is possible to grow these under trees as a shelter from frost they make a splendid show, and for this purpose give the ground a good dressing of poultry manure. This should be dug in and the Cinerarias planted 1ft. to 18in. apart, and for late winter flowering they are the brightest patch in the flower garden. Cinerarias are really a perennial, but are best treated as an annual. They are not difficult to grow, and for the brightness of their flowers are worthy of a trial.

Sweet Peas.—The winter-flowering varieties are the most popular; they give plenty of blooms for table decoration when flowers are scarce. Give the ground a good dressing of poultry or rotted cow manure; dig this in as deeply as possible; make a shallow trench, say, 4in. to 6in. deep; then sow the Sweet Pea seeds 1in. to 2in. deep and 12in apart. When growth is well advanced and signs of flower buds appear give them a watering with sulphate of ammonia. To do this a dessertspoonful of sulphate of ammonia should be dissolved in 1gall. of water, and this should be poured in the trench by watering can (without rose) as far as it will go, at the same time giving the Peas a good drink. This may be done twice weekly or every fourth day. Soot water is also beneficial to Sweet Peas. Both the above bring out the colour in the blooms more richly. A little extra attention in this way will repay you with much better class flowers.

BACON CURING.

At the April meeting of the Snowtown Branch the following paper was read by Mrs. A. Dolling:—Select a pig of about 180lbs. to 200lbs. dressed weight; a well fed Large White or Tamworth-Berkshire cross should weigh that at about eight months old. Next, a very cold night is essential for killing; if the carcass is not properly cold it will not keep. The carcass should be cut down the middle of the back while still hanging up, as it is better to handle for carrying inside.

Place on a table and cut each half into three pieces, first just past the shoulder blade and then close to the hind leg; the shoulder may be cut into convenient joints for roasting or pickling as desired, but cut off any surplus fat, which can be rendered down for the lard tin, which comes in very handy for cooking.

Next, take a round-pointed butcher's or working knife and cut the ribs off the bacon, being very careful to cut quite close to the ribs and not dig holes into the bacon. Trim the bacon; it will be much thicker on the backbone side than the bottom, so remove some of the lean meat to make it almost the same thickness all over. If left on the bacon that lean meat becomes very dry and hard when smoked. If it is cut off it comes in very handy for metwurst. Trim the ham into a nice shape and cut out the pelvis bone. Here again, care must be taken to cut very close to the bone or there will be an unsightly, gaping hole in it.

Have ready a clean pickling cask in a cool place. Make a brine of 2lbs. salt, 1oz. saltpetre, and ½lb. white sugar to every gallon of water; it takes about 8galls. or 10galls. of brine for pickling. Dissolve salt, etc., in cold water. The best method is to make about 3galls. of brinc at a time and put on the meat as it is ready. Put about 2galls. of brine in the cask, then put in hams first, then bacon; if possible, the ham's should fit alongside each other at the bottom of the cask. On top of the bacon, the pickling meat may be placed. Now pour on the brine until the meat is completely covered and cover with hessian to keep out flies, but it should not be too airtight. Hams and bacon should be taken out and turned once a week. Leave in brine for four weeks, then take out and put in a tub of cold water, soak for 24 hours, take out, press hams into shape, wipe with dry cloth and give a good sprinkling of pepper. Hang up to dry for a day of two before smoking.

Metwurst.—16lbs. meat, not too lean (about one part fat to five lean), 6ozs. salt, 1oz. pepper, ½oz. saltpetre, 3ozs. suger. Put meat twice through mincer, then add salt, pepper &c., and mix well. The saltpetre must be finely powdered to press through a fine sifter. Fill into skins and hang up for a day and smoke. Be careful not to get too hot. The meat for metwurst should be of the best and free from blood. The head should be carefully cleaned and cut in halves and soaked in cold water all night. Next morning, boil for about two hours with all the scraps from trimming.

White Pudding.—One part cooked liver, two parts fat, salt, pepper, cinnamon, and a small onion cut very finely and fried in fat until cooked without browning. The rest of the head and scraps should be minced and mixed with one cup of rice (before it is boiled). Boil in plenty of water until cooked, cut a few slices of stale bread into cubes, and pour on boiling water, enough to just soften. Add salt, pepper, pimento, majoram, and thyme to taste. When well mixed, put into baking tins and bake for about three-quarters of an hour in moderate oven. This will keep for more than a week and is very nice, if fried with eggs instead of bacon, for breakfast. If liked, it may be eaten cold or used in sandwiches for lunches.

DYEING.

Paper read by Mrs. C. Hancock at the April meeting of the Parrakie Branch:—

Always choose a good drying day with a slight breeze. Make the dye beforehand as directed on the packet. I make the dye and bottle it. It saves time to keep a bottle of dye handy, especially if tinting is done after washing day, for most colours fade with sunlight and washing. To get a pastel shade, pour a few drops out of the dye bottle into a small pan of water and use as a rinsing water last of all. Most of these suggestions are for silks, satins, or cotton goods, and to make a colour fast it is necessary to boil the materials. Do not boil woollen goods or silks; the former should have a lukewarm dye. Pretty shades can be made by mixing two or more dyes together—red and blue make a purple, or a little more red than blue will make the new "plum shade"; blue and yellow will make certain shades of green; red and yellow make orange; pink and blue (pale) make a lilac tone.

Do not forget to have plenty of salt in the water or dye bath, this helps to set the colour. Always have a piece of the material to experiment with before attempting to dye the material. When making the dye always stir well before putting in the material, and also add the salt at once. Another method is to stand the material in the dye for several days, and lift in and out of the water now and again to prevent streaks. Always remove all ornaments such as buttons, &c., as these articles will change colour, especially if boiling dye is used.

Rinse finally in clear rainwater until the colour runs clearly. I always add salt to this also, and be very careful about putting out on the line. Never wring the materials, but lift in and out of the dye bath and hang straight on the line soaking wet. When it is drying turn upside down. When almost dry press, and for a tweed material press into shape again with damp cloths.

COOKING COMPETITION.

The March meeting of the Millicent Branch took the form of a Cooking Competition, and was particularly well attended, between 80 and 90 being present, including visitors from the Coonawarra, Kalangadoo, Tantanoola, and Rendelsham Branches. Mrs. R. Oberlander (President) occupied the chair, and extended a welcome to the visiting ladies. During the afternoon, a pianoforte solo was rendered by Miss Foster, and Mrs. W. E. Willshire contributed a recitation. A competition was keenly contested. Great interest was taken in the Cookery Competition, and entries were numerous for most classes. Messrs. G. and A. H. Millhouse had no light task in making the awards. A 25-lb. bag of flour presented by the Golden Crust Company was won by Miss Kathleen Ey. The awards were as follows:—Pound cake—Miss J. Telfer, 1; Mrs. H. J. Hutchesson, 2. Sultana cake—Mrs. H. Edgcumbe, 1; Miss D. Osborne, 2. Sponge sandwich (under 21)—Miss Joyce Fensom, 1; Miss Gwen McIntyre, 2. Sponge sandwich (open)—Mrs. H. Edgcumbe, 1; Miss D. Osborne, 2. White scones—Mrs. H. Edgcumbe, 1; Miss K. Ey, 2. Date scones—Mrs. H. Edgcumbe, 1; Mrs. Graham Major, 2. Collection of pastry—Mrs. Thompson, 1 and 2. Collection of biscuits—Mrs. H. Edgcumbe, 1. Ribbon cake—Miss O. Lear, 1 and 2. Lamingtons—Miss M. Bennett, 1; Miss I. Fensom, 2. Cream puffs—Mrs. H. E. Holzgrefe, 1 and 2. Queen cakes—Miss O. Lear, 1 and 2. Coffee cake—Miss I. Fensom, 1; Miss M. Bennett, 2. Pasties—Mrs. R. Elton, 1 and 2. Scones made with Golden Crust self-raising flour—Miss K. Ey, 1; Mrs. R. Elton, 2. A pleasant and instructive afternoon concluded with the serving of afternoon tea, at which the members of the men's branch were entertained.

DISPLAY OF WOMEN'S HANDICRAFTS.

The April meeting of the Coonawarra Branch took the form of an "Exhibition," a display of women's handicrafts. An instructive afternoon was spent inspecting the large collection of very fine articles brought along for exhibition by members. Amongst the articles exhibited were knitted garments, various types of cushions, jug covers, duchess sets, table centres flowers made from wood pulp, dolls, crocheting, needle work, wood and basket work, various preserves, baking, also vegetables and fruit. Beautiful ancient china from far off countries was displayed by Mrs. and Miss Soper, some articles being purchased over 40 years ago from overseas. Much interest was also shown in two old coins belonging to Mrs. L. Teichelman.

A seasonable gardening talk was given by the President, Mrs. H. A. Beschke.

Twenty members and three visitors attended the meeting held on 3rd April, when an address, "The Making and Baking of Cakes," was given by Miss Ellie Campbell, Inspector of Domestic Acts, of the Education Department.

HOUSEHOLD HINTS.

Devlin's Pound.

The following were given by Mrs. J. L. Loffler at the meeting held on 24th March, which was attended by 10 members and 18 visitors.

Modern liquid cleaners are very labour saving. They do their work efficiently with very little personal energy or elbow grease. But there are other humble liquids that prove a great help in the running of a home.

(1) *Ammonia.*—This is a particularly useful article, no housewife should be without a bottle. If used when washing woollens and blankets it loosens dirt and softens the water. It is not advisable to use it for coloured woollens unless the shades are quite fast. A dull looking rug or carpet will show considerably brighter colours if washed over with a pail of warm water to which 2 tablespoons of ammonia are added. Hair brushes should be rinsed in water to which 1 teaspoon of ammonia has been added. In addition, ammonia will help to cleanse china, polish glass, and will speedily remove all grease from plates and dishes. Ammonia added to the bath water is most refreshing and will leave no "tide mark" around the bath.

Methylated Spirits.—This is another labour saving liquid. There is nothing quite so good as methylated spirits for cleaning windows and mirrors. Silver which has become tarnished can be cleaned in half the time if it is first rubbed over with a soft rag dipped in methylated spirits. If a little is added to rinsing water for white silk jumpers, blouses, frocks, or undies, there is less likelihood of them becoming yellow. Removing perspiration marks from silk is always an awkward problem, but it can be solved by putting the affected parts into a mixture of methylated spirits and ammonia for a few minutes. Afterwards wash well and the stains will be removed.

Kitchen Hints.—An old catalogue on the kitchen table is handy; on it can be placed any hot pots, and thus saves the oilcloth. Tear off the dirty page and continue until the book is used.

Tea towels and dishcloths will keep a good colour if aluminium saucepans are not put on an open fire. If they are put on the open fire the bottom should first be greased, and then before washing, this can be easily removed with a piece of old newspaper.

A lemon is almost indispensable in the kitchen. It takes stains from the fingers after peeling fruit and vegetables. Taps rubbed over with a lemon takes less polishing. Knife handles also can be cleaned.

The mincing machine can be used for grating candied peel; this saves time spent in chopping or slicing.

Warm to hot water removes grit, sand, and dirt from vegetables more quickly than cold water.

Unwanted pieces of cardboard when cut into strips make good kindling.

If troubled with watery eyes when peeling onions, hold them under water and peel from root to stem.

Laundry Hints.—Bloodstains should be soaked for ½ hour in lukewarm water to which a little salt has been added. Grass stains can be removed from silks by sponging with ammonia and water. New stockings should always be soaked in lukewarm water to which has been added 2 tablespoons of salt. Then squeeze out and dip them into warm soapy water. A small piece of soap dropped into the starch after the boiling water is added will prevent the iron from sticking. Powdered starch applied quickly to fruit stains on linen will often remove the marks. Let the starch remain on until it has absorbed the discolouration, then brush off and wash linen in usual way.

General Hints.—Vinegar and water will clean gilt picture frames. Furniture first rubbed over with a cloth dipped in vinegar and water will make polishing far easier, and no finger marks will show.

Kybybolite.

[Meeting held 10th March.]

To keep silver clean, after the usual washing, place in an aluminium saucepan with a piece of common soap, and pour in boiling water; dry quickly, and polish with velvet or chamois.

To save carpet or lino. near telephone, place mat made cheaply from a sugar bag, ornamented with strips of raffia.

To save constant re-papering of shelves in safes or dressers, use strips of lino.

To make stoves (old) keep the polish, use a mixture of bluestone and black lead.

Paint brick fireplaces with enamel (brown), to save constant cleaning.

To dust moquette furniture, cover with damp cloth and beat.

Wash lino. with a cloth dipped in stale milk, to prevent slipperiness.

Wipe inside of kitchen windows with a cloth moistened with a few drops of glycerine to prevent steaminess.

Save charcoal from fires to moisten with a few drops of kerosene or waste oil, and use for lighting fires in the mornings (a large spoonful is sufficient).

To remove stains from enamel bath, rub with a mixture of turpentine and a little common salt.

CASSEROLE COOKING.

Miss M. Mattiske read the following paper at the Pinnaroo meeting, held on 3rd April:—

Casserole cooking is the most savoury method of cooking, as food cooked in the glass or stoneware dishes retains all its flavour and nourishment. Very little stock or water should be used, as fish, meat, or vegetables cooked in casserole should cook in their own steam. A tight-fitting lid is essential. The casserole has many advantages over ordinary cooking utensils.

The cooking process, though slower, requires very little attention. All food values are retained, except vitamins. It always looks clean and attractive; food cooks more evenly in it; it can be served in the dish it which it is cooked; and last, but by no means least, "washing-up" is minimised.

Fruit of any kind can be stewed in the casserole, and cooked at the same time as the roast, thus saving fuel and washing-up. Vegetables suitable for cooking in casserole are peas, beans, Brussels sprouts, marrow, cauliflower, potatoes (new and old), carrots, turnips, onions, and parsnips. Cabbage and spinach are not suitable for casserole cooking.

Casserole of Fruit.—Fruit, sugar, a little water, and flavouring. Peel the fruit, remove stones or core, and cut into slices. Boil the required quantity of sugar and water together for 1 minute, pour over the fruit, cover with lid, bake in a slow oven until fruit is soft; serve hot or cold. Apples may be cooked either sliced or whole, adding lemon rind or cloves as flavouring; pears, whole or sliced, adding lemon rind, cloves, or ginger as flavouring; quinces, whole or sliced.

To Cook Vegetable in Casserole.—Prepare vegetable in usual way; place in casserole, sprinkle with a little salt; add a pinch of carbonate of soda; if green vegetable, pour over about 1 cup of water (cold or hot); cover with lid; place in oven 25min. to 40min. before the roast is to be dished; drain off all liquid, and serve in the dish in which it was cooked.

Casserole of Liver.—One lamb's fry, carrot, turnip, onion, flour, fat, water or stock, rashers of bacon, parsley, salt, and cayenne. Soak liver in cold, salted water for 20min. Peel the vegetable, and cut in large dice. Melt the fat, and fry the vegetable for a few minutes. Remove from fat, and place in casserole. Wipe the liver dry; cut in slices, dip in flour, and fry in the fat until browned. Drain well, and place in casserole on bed of vegetables. Add some flour to the fat, allow to brown; add water, and stir till it boils and thickens; add salt and cayenne. Strain over liver, add the bacon, cut into strips; cover with lid; place in a moderate oven, reducing heat after 10min. Then cook slowly until liver is tender. Add more liquid, if necessary; remove any fat from the top of the stew with a spoon, then paper; sprinkle with chopped parsley, and serve at once.

Savoury Casserole.—2lbs. topside steak, 1 onion, carrot, salt, pepper, rasher of bacon, Worcestershire sauce, tomato sauce, vinegar, parsley, and a little stock. Lay steak in casserole, grate carrot and onion, mix the sauces, vinegar, stock, salt and pepper well together, add onion and carrot; pour all over meat; stand for 10mins.; cover with lid; place in a moderate oven, and cook slowly for about 1 hour. Remove all traces of fat, sprinkle with chopped parsley, and garnish with rolls of bacon.

Chicken en Casserole.—1 chicken, 2 small onions, 4 slices of fat bacon, salt, pepper, a little flour, stock or water, mushrooms (if liked). Cook the giblets slowly in water until tender, and use the liquid as stock. Lay two rashers of bacon in a well-greased casserole; sprinkle with finely chopped onion and mushrooms; lay in the seasoned chicken, put remainder of bacon on top; sprinkle in a little flour, add the stock, cover with lid; bake in a slow oven until tender; serve very hot.

Steak and Tomato Casserole.—Topside steak, 2 onions, 4 large tomatoes, salt, pepper, a little water, flour, fat. Cut steak in neat pieces, and fry in fat until brown; drain, and place in casserole. Add flour to fat, with salt and pepper, and brown evenly. Cut onion and tomatoes into slices, and lay on steak. Pour over hot gravy; cover with lid, and bake in slow oven from 1 to 1½ hours. Serve very hot, sprinkled with parsley.

THE KITCHEN GARDEN.

Eleven members attended the meeting of the Mudamuckla Branch held on 18th March, when the following paper was read by Mrs. Reincke:—The first point to consider is the site for the garden. On the side of a hill is best; the soil is not so hard as that in the flats, and it can be more easily got into working order. If the land is inclined to be hard apply a few loads of sand and add plenty of stable manure. The garden should be well fenced on the north, west, and south sides to protect the vegetables from strong winds. If artificial manure is to be used sprinkle it lightly among the plants when growing, hoe, and water thoroughly. If possible have the garden near the house, then the men can do the digging. Another advantage of this location is that the vegetables can be brought in just as they are wanted for use, and one has more chance of keeping birds away. Before any seeds are put in be sure they are good, or this will make late crops. Use fresh seed each year. If the best cabbage or cauliflower goes to seed save it for sowing next year. It is advisable to have both early and late varieties of all crops so that vegetables of some kind will be available all the year round. Turnips and swedes grow quite well in the paddock. Always plant seeds in tins or boxes in a sheltered place until they are up, and gradually move them out until they get plenty of sun, and they will be hardened off ready for planting out. Several weeks before transplanting sprinkle well with sulphur to check any pest. Do not plant seeds in too rich a soil.

After the beds have been dug and well aired and manured choose a dull day or evening for setting out the plants. Where there is a small family do not put out a lot of plants at once; it is better to plant just a few each month so that they will not all be ready at once. Carrots, parsnips, and red beet mature a fortnight or so earlier if not transplanted. Plant these where cabbages, &c., have been grown, but see that the land is dug well and no manure added, because the latter tends to make "forked" vegetables.

It is advisable to have the beds banked up around the edges if trenches are not used, to be able to give the ground a good watering. Two good waterings a week in summer are better than a sprinkling every morning or evening. Most root vegetables can be grown all the year round; the summer here is almost too hot for any green crop except silver beet unless grown in a nice shady place.

Put in tomato seed no later than July or August so that the plants can be set out in September. Most of the danger of frost is then over, and should there be a frost and they are not covered, sprinkle water over the plants before the sun gets on them. Put in melons, cucumbers, pumpkins, &c., during September and October. These unfortunately do not set well until January or February. If there are no bees or ants about, pumpkins and vegetable marrows have to be inoculated. This is best done early in the morning before the flowers droop. Always try to trellis tomatoes; it keeps the bushels more healthy, and the fruit does not rest on the ground. If pruned, crops will be heavier, and the fruit will be more even in size.

Pumpkins, melons, &c., are grown very much alike, and once they get a start need very little attention. If the wind affects them put down some boughs for them to creep on to. Do not throw away soot from the stove, sprinkle on the carrots and onions, and water well. Rhubarb grows well with plenty of water and manure. Celery, too, can be grown easily if it is only used for flavouring. Beans do not do very well unless well sheltered. North winds cut them badly. However, the Seven-year Bean and the New Guinea Butter Bean are all right if protected from frosts. Peas give satisfactory crops without much attention if a dwarf kind is grown. Kohl Rabi also does well, and can be used several ways. All winter seeds should be sown early in March so that they will go ahead when the first rain comes.

Remember when cooking vegetables all that is grown above ground cook in boiling water, and all that is ground under ground put into cold water.

Varieties to Grow.—Red Beet—Obelisk, or Turnip-rooted; Silver Beet—Curly Leaf; Cabbage—Earliball, or Succession; Cauliflower—Early Eclipse; Carrot—Early Horn, or Chantenay; Parsnip—Hollow Crown; Cucumber—Apple-shaped, or Crystal Apple; Kohl Rabi—Large Purple; Lettuce—Iceberg, or Imperial; Onion—Early Barletta, or Brown Spanish; Tomato—Early Dwarf, or Navel King; Pumpkin—Queensland Blue; Melon Pie—Citron; Melon, Water—Ice Cream, or Sugar Stick; Turnip—White Stone; Swede —Purple Top.

ICING AND DECORATING A BIRTHDAY CAKE.

[Paper read by Mrs. A. Kloeden, at a meeting of the O'Loughlin Branch, on the 5th March, 1936.]

When the cake is intended for an adult, most of us like to be given a free hand with rich ingredients; small children are naturally better suited with fairly plain cake of the Madeira type. As long as the icing and decorations are above reproach, no child thinks twice about the comparatively plain cake beneath. A rich fruit cake is stored as a matter of course for some weeks before the appointed birthday. It is unwise to ice a cake of this type until a few days before it is needed, as the royal icing becomes brittle and difficult to cut.

There is always the chance of the icing becoming discoloured through lengthy contact with the moist, fruity cake, and a yellow blotched icing is certainly not attractive.

The first coating of the cake should be of almond icing. As ground almonds are very seldom procurable in our country stores, and are fairly expensive, I use the coconut icing, which consists of whites of 2 eggs 1 cup of desiccated coconut and 1lb. icing sugar. Stir well together in a thick paste. For ease in handling the cake you will find it a good plan to stand the cake on an upturned soup plate. Lift the whole thing to a convenient working height by placing it then on an upright jar of some kind. You will be able to turn this as required, without touching the cake.

When putting on the first coat of coconut icing brush the cake free of all crumbs with a damp cloth dipped in hot water. Keep the cake moist whilst putting on the icing and let it stand till next day.

Next comes the royal icing, which gives the smooth, firm surface so necessary for icing decorations. *Royal icing*—1lb. icing sugar, 2 egg whites, a few drops of lemon juice, a few drops of wash blue, and a few drops of glycerine.

Each ingredient plays an important part. The egg whites, used instead of water or milk, give the full characteristic firm texture to the icing. Lemon juice is mere flavouring, but the glycerine prevents the icing becoming over-brittle. A few drops of washing blue are indispensable when a pure white icing is required; both the blue and glycerine are tasteless and harmless.

Use a broad, pliable knife and ice the sides first, working any surplus icing up over the top edges. Next place a little icing on top of the cake and smooth it carefully to the edges. To obtain the smooth, shining effect, dip the knife in a deep jug of boiling water, shake it free of surplus moisture and smooth it carefully over the icing. Then let it stand till next day. Then comes the really interesting part of the work. So far all cakes are more or less alike, but with the decorating every woman can carry out her own ideas to produce something beautiful, original, or even definitely amusing. The modern metal icing pump makes the work very simple (though I prefer the rubber icing bags and tubes). With its aid you can make straight lines, lettering, scrolls and roses, and all manner of decorations.

Colour plays a big part in some designs, and touches of pink or green and silver cachous can be used most effectively.

If the design you fancy is beyond your drawing powers, there is still a way out. First find the required illustration and draw or trace it on white paper. Then lay the paper on the hardened surface of the cake, and with a needle prick it through on to the icing. It is then a simple matter to follow the dots with the thread of the icing from the tube. You will see many possibilities in this method.

SUMMARY OF REPORTS RECEIVED.

Branch.	Date of Meeting.	Attendance.	Subject.	Secretary.
			WOMEN'S BRANCHES.	
Yurgo	27/4/36	—	Annual meeting.........	Mrs. R. E. Sanders
Monarto South .	25/4/36	16	"Dressmaking"—Mrs. E. A. Thomas	Mrs. F. W. Liebelt

AGRICULTURAL VIEWS AND COMMENTS.

MISCELLANEOUS.

Agricultural Bureau Conferences, 1936.

Eyre's Peninsula (East), at Kimba (Kelly Branch), Tuesday, 4th August (Mr. F. R. Illman, Box 64, Kimba).

Southern, at Inman Valley, Thursday, 20th August (Mr. S. F. Hacklin, Inman Valley).

Hills (altered to Gumeracha), Thursday, 27th August (Mr. R. G. Almond, Secretary).

Murray Lands (East), at Alawoona, Tuesday, 6th October (Mr. Angus Thomson, Alawoona).

Eyre's Peninsula (Central), at Minnipa, Friday, 23rd October (Mr. H. E. Broad).

Fruit (non-irrigated), at Greenock, Tuesday, 3rd November (Mr. A. Schubert, Greenock).

Each Conference will commence at 10.30 a.m. Members of Branches are invited to submit papers and questions for the agenda of the Conference in their respective districts.

Agricultural Shows.

We have been advised by Secretaries of Agricultural Show Societies that their shows will be held on the following dates:—

Northern Yorke Peninsula, Field Trial and Show—Bute, Wednesday, 26th August.
Naracoorte Sheep Show, Tuesday, 15th September.
Saddleworth, Saturday, 19th September.
Wudinna, Wednesday, 23rd September.
Waikerie, Saturday, 26th September.
Balaklava and Dalkey, Saturday, 26th September.
Eudunda, Wednesday, 30th September.
Laura, Wednesday, 30th September.
Kapunda and Light, Saturday, 3rd October.
Wirrulla, Saturday, 3rd October.
Burra Burra, Saturday, 3rd October.
Karoonda, Wednesday, 7th October.
Murray Bridge, Thursday, 8th October.
Cleve, Saturday, 10th October.
Moonta, Saturday, 10th October.
Blyth and Kybunga, Saturday, 10th October.
Loxton, Wednesday, 14th October.
Kimba, Wednesday, 14th October.
Colton, Wednesday, 14th October.
Yallunda Flat, Wednesday, 14th October.
Penola, Wednesday, 14th October.
Strathalbyn, Wednesday, 14th October.
Tailem Bend, Saturday, 17th October.
Mannum, Saturday, 17th October.
Paruna (Brown's Well), Saturday, 17th October.
Maitland, Wednesday, 21st October.
Pinnaroo, Wednesday, 21st October.
Mount Gambier, Wednesday and Thursday, 21st and 22nd October.
Willunga, Thursday, 22nd October.
Clare, Saturday, 24th October.
Port Elliot, Saturday, 24th October.

Kingston (South-East), Saturday, 24th October.
Minlaton (Central Yorke Peninsula), Wednesday, 28th October.
Tatiara (Bordertown), Wednesday and Thursday, 28th and 29th October.
Yankalilla, Saturday, 31st October.
Millicent, Saturday, 31st October.
Naracoorte Show, Wednesday, 4th November.
Kingscote, Kangaroo Island, Thursday, 5th November.
Mount Barker, Saturday, 7th November.
Woodside, Saturday, 14th November.
Kalangadoo, Saturday, 14th November.

Subsidy on Bulls.

At the Congress held in 1935, the Roberts and Verran (Eyre's Peninsula) Branch moved for an increase in the subsidy for the purchase of bulls. Reference was made to the high transportation costs, and a resolution was carried asking an increase in the subsidy by the Government paying the cost of transport. The Government has now approved of this by a regulation, under the Dairy Cattle Improvement Act, which gives the Minister of Agriculture authority to pay to the approved purchaser 50 per cent. of the boat charges, freight, and wharfage to Eyre's Peninsula, Yorke Peninsula, Kangaroo Island, or other island off the coast of South Australia.

Imperial Economic Committee—Grain Crops: World Production and Trade.

A report on "Grain Crops," covering the period 1928 to 1935, which has just been published by the Imperial Economic Committee, shows the improvement which has recently taken place in the statistical position of the wheat trade. The encouragement given to agriculture, especially to wheatgrowing, in various European countries, together with the increased restrictions on imports, greatly reduced the demand for overseas grain, and led to the accumulation of large stocks; this situation has altered materially in the past year and now, thanks to reduced acreage and drought, it appears probable that the world carry-over on 1st August next will be less than 17 million tons. In 1934 the carry-over exceeded 31 millions tons. Expectation of the gradual liquidation of these large supplies led, during 1935, to an advance in price to the highest level reached since 1930.

The report is mainly a statistical analysis of the world production of and trade in wheat, barley, oats, maize, and rice during the past eight years. It shows that the 1934 area and production of each of these five crops was lower than the average for 1928-1933, and that the Empire's share of the total stands at about 23 per cent., though for rice alone 56 per cent of the world's production is grown within the Empire. The most notable change during this period is the increased production of wheat, barley, and oats in the U.S.S.R., which has recently replaced the United States as the world's largest producer of these three commodities. Within the Empire Canada was formerly the largest producer of wheat and barley, but India now leads in these crops as well as in maize and rice.

International trade in these cereals and in wheat flour fell generally during this period with the United States the chief sufferer. Exports of these six products from the United States amounted to 5,646,000 tons in 1928, but, after a steady decline, to only 547,000 tons in 1935. Canadian exports, which at 11,759,000 tons were abnormally large in 1928, fell to 5,251,000 tons in 1935. From Australia exports have fallen since 1931, but have remained above the level of 1928-1930. The statistics of the importing countries show the other side of the picture: imports of these six commodities into France, Belgium, Netherlands, Germany, Switzerland, and Italy fell from 17,479,000 tons in 1928 to 8,861,000 tons in 1935. A section of the report is devoted to an exposition of the forms of import restriction imposed, and the duties levied by these six countries which have contributed substantially to the shrinkage of the European market.

A feature of the report is the calculation of the Empire's net position with regard to the trade in each of these products. The Empire has for sale to foreign countries a considerable surplus of wheat and flour which frequently amounts, in the case of wheat alone, to more than 2,000,000 tons. India normally has a surplus of rice sufficient to meet the import requirements of the other parts of the British Commonwealth, but for the secondary cereals it is necessary for the Empire to have recourse to foreign sources of supply.

THE HUMUS VALUE OF VARIOUS PLANTS FOR COVER CROPS.

Replying to a question as to the value of various plants for cover crops which was submitted by a delegate from the Block E Branch at the River Murray Agricultural Bureau Conference at Renmark, Mr. W. J. Spafford (Director of Agriculture) said the humus value of green-manuring plants will be decided by the quantity of easily-decomposed organic matter that is produced in a given time. When green manuring in the orchards of South Australia, and particularly in the fruitgrowing areas of the River Murray, the sole object is to increase the organic matter content of the soils. Humus is fully decomposed organic matter, and so long as fruitgrowers produce profuse growth of any plants which are easily decomposed, they are doing all that can be desired in this direction.

Plants grown for green manuring return to the soil only what they take from it, except for the carbon and oxygen taken from the air, and in the case of legumes, some nitrogen as well. The mineral matter, of course, is brought from some depth, and is deposited near the surface of the soil when the plants are ploughed in.

The importance of using nitrogen-collecting plants for green manuring has been overstressed, for although the nitrogen is valuable, unless used by plants soon after it is liberated, it is leached out of the soil, particularly in irrigated areas. On the other hand, several of the forms of bacteria responsible for the decomposition of the green manure collect large quantities of nitrogen from the air whilst doing this work.

On the River Murray fruit areas the deciding factors as to what are the most suitable green-manuring plants for growing between the rows of vines or trees will always be connected with what can be grown between the times when water is available, and what can be put into the soil without injuring the roots of the trees or vines.

It seems that one of two methods of growing green-manuring crops may be followed:—(1) By taking a special watering in March and growing rye (or other cereal) or mustard, and ploughing the crop under not later than July; (2) by ploughing thoroughly in winter, and on the irrigation given at the end of July seeding the land with mustard or rape, and instead of ploughing the crop under, chop up the growth with a disc cultivator, leaving the organic matter on the surface, as farmyard manure is left, until ploughed under the next winter.

THE CUMMINS BUTTER FACTORY.

On 19th June what might be considered a very big step in the development of Eyre's Peninsula took place at Cummins in the official opening of the Cummins Butter Factory.

The Hon. A. P. Blesing, M.L.C. (Minister of Agriculture), was very interested in this indication of development, and being unable to attend personally asked Mr. A. W. Christian, M.P., to represent him and to state that in his opinion the opening of this factory, besides helping to cater for the dairy produce of Eyre's Peninsula as a whole, must be a decided boon to landowners of the surrounding district. He pointed out that, during the last few years, the production of dairy produce in the shape of butter had increased from about 5 tons per week to approximately 20 tons of butter per week. The encouragement of sidelines had been the policy of the Department of Agriculture for some years, and it was very pleasing to see that there was enough faith in the country to spend local capital in the erection of an up-to-date butter factory.

Mr. Clarke, the proprietor of the Cummins Butter Factory, has spared no expense in providing an up-to-date buttermaking plant, and the fact that the farmers' cream can now be treated a very short time after leaving the farm should go a long way to improving the quality of the butter and help the farmers to receive remunerative prices for their products.

In his opening remarks Mr. Christian explained the Butter Equalisation Scheme and Dairy Produce Act. He pointed out that this Act was purely a marketing Act to enable farmers to receive comparatively profitable returns, and to obtain some advantage from the Australian price. The legislation was working very satisfactorily, and had at least given to dairymen an additional 2d. per lb. for their produce.

Mr. Christian was assisted at the function by Mr. H. B. Barlow (Chief Dairy Instructor) who represented the Department of Agriculture in the unavoidable absence of the Director (Mr. W. J. Spafford). Mr. Barlow said that the factory at Cummins was under departmental supervision, and farmers could be assured that their produce would receive the same supervision as if it were treated on the mainland. He considered that the factory was quite comparable with the majority of mainland factories, and if given the support it deserved should be a wonderful acquisition to the district.

At the invitation of Mr. Clarke about 250 local farmers and their wives attended the opening ceremony, and after inspecting the factory and plant were entertained by Mrs. Clarke at afternoon tea.

Museum of Agricultural Implements.

The Minister of Agriculture (Hon. A. P. Blesing) is now in the position to state that the Committee recently appointed by him for the purpose, and consisting of the Director of Agriculture (Mr. W. J. Spafford), Messrs. H. T. Gray, G. H. A. Mahood, L. S. Smith, and Colonel C. P. Butler (''Yattalunga'') is functioning, and has made a start with the collection of ''old'' implements for exhibition in a building to be provided at the Show Grounds. The Government is pleased to provide freight for any article of agricultural equipment which the committee considers suitable for the proposed museum, and as some odd repair work will be necessary for some of the articles, the sooner donors supply them to the committee the more chance there will be of having them ready for the forthcoming Centenary Show. The type of the placard to be placed on each article donated has not yet been decided upon, but in any case, it will contain the name and address of the donor, and the details supplied as to the history of the exhibit.

The Secretary to the Minister of Agriculture, or any member of the committee, will be pleased to hear of any old agricultural implement or article of agricultural equipment which a person is prepared to donate for this very laudable attempt to get together a historical collection of things that have had something to do with our agricultural progress. Nothing will be too small or too large if it fulfils the requirements of the scheme, and the Committee will give consideration to every offer as soon as possible after it has been made.

Meat Inspection.

The Library of the Department of Agriculture acknowledges the receipt of a ''Textbook of Meat Inspection,'' by J. Drabble, B.V.Sc., published by Messrs. Angus and Robertson, of Sydney. This work is eminently suited for the requirements of those studying for meat inspection examinations. It is a handy reference book for the Meat Inspector, and contains concise information on all phases of this work. The price of the book is 21s.

Trees and Diminishing Rainfall Averages.

The following question, asked by a delegate from the Eurelia Branch at the Upper North Bureau Conference on 15th July, was referred to Mr. G. J. Rodger (Conservator of Forests), of the Woods and Forests Department, who says:—

The extent to which the reduced rainfall, which it is stated has been experienced for a number of years, can be attributed to the destruction of timber in the farming districts and the wholesale dying of the bushes and timber in the pastoral country, cannot be definitely stated.

Apart from the time required, the great obstacle to arriving at a safe conclusion as to the effect of vegetation on precipitation lies in the difficulty of choosing rain gauge stations where all the factors are identical, except vegetative cover. There is often, for instance, an unevenness in precipitation at nearby stations where the physical surroundings appear to be similar.

It is known that the air of forests is cooler and moister than air in the open, and it would seem, therefore, that forests should have some influence on precipitation. On the other hand, precipitation depends chiefly on wind currents and other powerful agencies, compared with which the influence of the forest must be very small.

Although the comparison of numerous observations of precipitation at stations within and outside the forest in various parts of the world show conflicting and extremely varying results, the balance of the evidence appears to favour the contention that forests increase precipitation, though to what extent is very uncertain.

As far as the very local effect is concerned, the larger percentage of observations indicate that there is a large precipitation over the forest, the excess varying from 1 to nearly 50 per cent. Over the period of 10 years, observations in North Germany indicate that the increase in precipitation over forest country is very small at sea level, but increases rapidly with elevation, rising to nearly 50 per cent. at about 2,500ft.

A comparison was made over a period of 7 years of the rainfall data in a small pasture surrounded by large forests near Nancy, France, with the precipitation at a station at the same elevation in a nearby region practically without forests. The precipitation at the station surrounded by forests was considerably more than at the stations in the open, but varied with the season, as shown in the following table:—

Spring	7 per cent.
Summer	13 per cent.
Autumn	23 per cent.
Winter	21 per cent.

Observations on the steppes of southern Russia, where 5,000 acres of forest were established in entirely open country; are of considerable interest. The forest was established between 1845 and 1863. Two stations, one over the forest and one outside, were established in 1892. During the period 1893-97 the precipitation over the forest was 23.9 per cent. more than in the open. Bavarian observations and others made elsewhere within recent years show much less influence of forest vegetation on local precipitations than indicated by the above data.

Compared with the local effect, it is often contended that the effect of forest vegetation on precipitation is much greater over vast areas, often miles in extent. The forest cover profoundly influences the evaporation of water from the land. Although evaporation from the soil is much less in the forest, the loss of moisture from evaporation, combined with the loss from transpiration through the foliage, may be, and usually is, much greater than the loss from denuded areas.

The more abundantly developed the vegetative cover, the faster the moisture is returned to the area through the evaporation and transpiration combined, and the larger amount available for re-precipitation farther inland. Thus Breckner, of Germany, has pointed out that it is often evaporation from the land that supplies the atmosphere with moisture for precipitation, even more than evaporation from the sea.

Zon, R., of U.S.A., in a paper entitled, "The Relation of Forests in the Atlantic Plain to the Humidity of the Central States and Prairie Region," contends that forests, by increasing the evaporation and transpiration at the expense of the surface run-off, enrich the passing air currents, and in this way help to carry additional moisture into the interior of continents. He concludes that 78 per cent. of all the precipitation for the land area is supplied by the area itself, and that the amount supplied is largely dependent upon the forests. Thus, he points out that in the south-eastern United States as soon as the moisture-laden winds from the Gulf of Mexico reach the land they are cooled and begin to lose part of their moisture, but as they move to the north-west they become dryer, and precipitation decreases. If precipitation over the land depended entirely on the amount of water brought by the prevailing winds from the Gulf, abundant precipitation would be confined to a narrow belt close to the sea. Zon contends that in the south-east of U.S.A., if the winds in their passage to the north, north-west, and north-east did not encounter the forests bordering the coast, and were not enriched after precipitation by the large amount of moisture from them, the rainfall farther inland, even in the prairie States, would be far less than it is.

In the same manner it is argued that the forests of Sweden have an important influence on the precipitation in the countries to the east into which the prevailing winds blow.

In conclusion it might be said that although meteorological data cannot be assembled to prove definitely that forest growth appreciably increases the total amount of precipitation, theoretical conclusions certainly point to a distinct influence of the forest on precipitation over vast regions of non-mountainous country.

Apple and Pear Industry—Extension of Research and Instructional Facilities.

Consequent upon the recent provision of a Commonwealth grant for the purpose of furthering research into problems of apple and pear growers, and for extending instructional facilities in the several States, three new officers have been appointed to the Horticultural Branch of the Department of Agriculture.

Mr. H. K. Kemp, B.Ag.Sc., has been appointed Horticultural Research Officer, and will undertake in co-operation with present staff investigational work on Codling Moth, the removal of spray residue, Black Spot, fertilisers, &c. Experimental and demonstrational spraying plots will be laid down in representative districts, and it is hoped that growers will take a keen interest in the progress of the proposed field work.

Messrs. E. B. Chamberlain and G. Harris have been appointed special Instructors, and will devote their whole time to advisory work in connection with the reworking of unsuitable varieties of apples and pears, and to instruction in packing of these fruits for export and Interstate markets.

Mr. Chamberlain will carry out this work in all districts north of the main road through Norton's Summit to Mount Torrens, and Mr. Harris will take charge of districts south of this road.

Later in the season, reworking demonstrations will be given in different districts, and in the meantime the officers are available to discuss reworking with individual orchardists, and to render any advice or assistance which may be desired.

During the apple packing season these same officers will act as apple and pear-packing instructors.

All apple and pear growers who are interested in either reworking of out of-date apple and pear varieties or in any phase of preparation of these fruits for export, are invited to make contact with the Horticultural Branch office, Exhibition Buildings, North Terrace, Adelaide, or with the special Instructor in their area. Letters may be addressed to Mr. E. B. Chamberlain at Paracombe (Telephone, Houghton 28), and to Mr. G. Harris, Balhannah.

In due course demonstrations in methods of reworking and in packing will be arranged, and any Agricultural Bureau or group of growers desirous of having such demonstrations in their district are asked to communicate with the Chief Horticultural Instructor.

Production of Butter and Cheese.

Production of butter and cheese for May, 1936, was as follows:—Butter, 759,613lbs.; cheese, 415,851lbs.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

Dog with Distemper.

"Millicent" reports puppy 4 months old, froth at mouth, jaw and neck swollen, and partially paralysed. Body is twitching and dog has difficulty in drinking.

Reply—The trouble with the dog is undoubtedly distemper in a very bad form. Give milk foods only and keep him very warm and quiet. It is impossible to cure the spasmodic twitching, but the following mixture may help:—Potassium bromide, 10 grains; aceto-salicylic acid, 10 grains; bismuth carb., 10 grains; dimol, 5 grains; water, 2 drachms. Get 4ozs. of this solution and give 2 teaspoonfuls twice a day.

Greasy Heels.

"Wasleys" asks for a cure for greasy heels in horses.

Reply—It is difficult to obtain a complete cure. The following treatment is advised:—(1) Wash affected area thoroughly with soap and water containing a little washing soda. (2) Apply the following dressing for a few days:—Copper sulphate, 5 teaspoonfuls; zinc sulphate, 5 teaspoonfuls; water, 1 pint. (3) Give internally one tablespoonful of Fowler's solution of arsenic night and morning for 14 days. To give, mix in a small damped feed.

Horses with Severe Cold.

"Wasleys" reports horses affected with a bad cold.

Reply—Have the following electuary made up:—Powdered camphor, ½oz.; powdered myrrh, ½oz.; liquid extract of belladonna, 2 drachms; potassium chlorate, 1oz.; honey, 4ozs.; glycerine, 4ozs. *Directions*: Place a tablespoonful on the back of the tongue three times daily. Keep the animals warm—do not work or allow to become overheated—give green foods if possible and a bran mash twice a week with 3ozs. of Epsom salts in each.

REARING ORPHAN LAMBS.

Seeking advice as to how to rear orphan lambs, the Secretary of the Wolseley Branch of the Agricultural Bureau has been advised by Mr. A. H. Robin, B.V.Sc., of the Stock and Brands Department that orphan lambs may be successfully reared on cow's milk, though close attention is necessary for the first month. For the first week, the lamb should get some ewe's milk if possible by letting it suckle from a ewe whose lamb is not yet old enough to take all of her milk. The cow's milk used should be from a cow giving milk rich in fat, if necessary additional cream may be added. Always use milk from the same cow. During the first few days and nights, feed the lamb only small amounts at a time (not more than 2 or 3 tablespoonfuls), but it must be fed often—every 2 or 3 hours. Feed the milk from a bottle with a medium sized nipple attached and always feed at blood heat (about 100° F.). Carefully wash bottle and nipple after each feeding. After the lamb is 2 to 3 weeks old, three feeds a day should be ample.

THE MILK SUPPLY OF LONDON.

REPORT BY MR. W. A. HAMILTON, M.P.

To His Excellency Sir Winston Joseph Dugan, Major-General, Knight Commander of the Distinguished Order of Saint Michael and Saint George, Governor in and over the State of South Australia and its Dependencies in the Commonwealth of Australia.

May it please your Excellency:

In pursuance of the Commission issued to me by your predecessor, Sir George John Robert Murray, authorising me to report upon the Milk Supply of London, I have the honour to present my first and final report.

I commenced my inquiry into the Milk Supply of London by visiting the head office of the Milk Marketing Board at Thames House, London, where I was courteously received by the Secretary, and given whatever information I asked for.

CONTROL.

The Milk Marketing Board was created under the authority of the Agricultural Marketing Act, 1931, and the Milk Marketing Scheme applies to the whole of England and Wales. As by far the larger part of the milk used in London is necessarily produced outside of the metropolis, it was expedient to make some inquiries further afield, and I obtained information of a general as well as a specific character, all of which has a direct bearing on the milk supply of London.

The present scheme was established with the object of helping the dairymen of England, who, as a result of ruinous competition and the general trade depression, found it almost impossible to get a living. Indeed, many thousands could not get a living by producing milk, and eked out an existence by producing other foodstuffs, much of which they consumed themselves, or sold at very low prices at the nearest market town. At the consuming end of the industry the fierce competition for customers made it impossible for distributors to make a reasonable profit. As soon as one price-cutter was forced out by the law of supply and demand, another took his place, and there was no order or regularity in the industry. It is not an exaggeration to say that it was in a state of chaos.

Under the scheme, England and Wales are divided into eleven regional districts, and there is a local Board for each district to carry out the necessary details. The Central Board consists of 16 members elected by the milk producers, two nominated by the Minister, twelve regional members, and two co-opted by the elected members of the Board. The Board has power to elect a Chairman and Executive Committee, and such other committees as may be necessary, and it is paid for its services. The whole of the milk used by the population of London and the great centres throughout the country is more or less controlled by the Board and the regional committees.

PRODUCTION.

The Milk Marketing Scheme was commenced on the 9th October, 1932, and has been in operation from then to the present time. It is a compulsory scheme, under which 160,000 farmers, hereinafter called the first class, are registered and controlled as regards the production and sale of their milk, and about 70,000 producer-retailers, called the second class, who are also registered. A farmer having not more than four milch cows is exempt from registration. The retail price for the producer-retailers is fixed at the same rate as other distributors have to charge. The Board also buys surplus milk from them.

The first class of producers must sell their milk to the Board, and it is all received as "liquid milk," which is the milk ordinarily supplied to distributors for immediate use as food. The surplus not required by distributors is sold to manufacturers of various milk products, such as dried milk, butter, cheese, and many other things into which milk is manufactured. (It is interesting to learn that the horn rims used on spectacles, usually supposed to be tortoiseshell, are made of compressed milk). The price for liquid milk varies at different times, but is usually somewhere in the region of 15d. per gallon. The average price for milk required for manufacturing was about 3½d. per gallon. As only the surplus is sold at this latter figure, it has not affected the farmer so much as yet, but the more surplus milk there is the lower the general price must be, because the prices are averaged out, and while the manufacturer obtains the milk for 3½d., or thereabouts, the farmer, notwithstanding that liquid milk was sold for 1s. 3d., may only get something in the region of 11d. net. The above prices were supplied to me at the commencement of my inquiry early last May, but when the Board's balance-sheet was presented on 6th June it was shown that they were much better. Further reference to this is made in the section under "Distribution."

As the Board is the central authority for the purchase and sale of all milk produced under the scheme, with the exception of that retailed by the producer-retailers, its turnover is necessarily very large. Last financial year its income and corresponding expenditure was a little under £36,000,000. A levy of one farthing per gallon has recently been made to provide for the expenses of the Board. This has not all been spent, there being an amount in reserve of £295,349. The expenses of administration for the year under review amounted, approximately, to one-twelfth of a penny per gallon of milk sold. Each producer is compelled to sign a comprehensive agreement, binding himself to the conditions laid down by the Board in regard to the quantity of milk that he can produce each day, the number of cows that he keeps, the level delivery of milk (which means that the Board requires so many gallons from him per day), where he shall deliver it (whether at a railway station or whether the Board shall collect it at his farm), and numerous other provisions, all of which tie him absolutely to the Board for the purchase of and consequent payment for the milk that he produces. The regional price is fixed after calculating quality, quantities, railway and picking-up charges, and various other things, and when this is done, cheques for the produce are sent out to each individual producer.

An important feature of the scheme is that outlying districts, such as Devonshire or distant parts of Wales, receive the same price as a producer near, say, London, or any other great centre of population. This was done partly to give all producers a nearly equal opportunity of making a living, and partly to prevent supplies of very cheap milk being rushed in at convenient periods to the great centres, the effect of which was to cut down the local price obtained by the producers. It is not difficult to conceive that producers near London were much better off than those in more remote parts of the country because of this difference in distance from the best market. The scheme now nearly equalises the returns to the producer in every region. Therefore one effect of the scheme has been that producers near great centres of population are often worse off than they were before, but the majority, taking the country as a whole, are better off.

DISTRIBUTION.

The operations of the Board under this heading are of large dimensions. The total quantity of milk bought and sold last year was nearly 913 million gallons; 71 per cent. of this quantity was used as "liquid milk" for domestic purposes and 29 per cent. for manufacturing. The average realisation value of milk for manufacturing was 4.92d. per gallon. This price was raised by assistance, provided by the Government, to 5.92d. per gallon. The above figures are taken from the Chairman's

Statement to the meeting held on 6th June. The effect of the Government grant has been to raise the pool prices to the producers by ⅜d. per gallon. When this was averaged out on the price of liquid milk it brought the whole production to 12.125d. per gallon.

As the result of negotiation by the Board with the distributing Companies and private firms and manufactures, a better price was obtained last year, and this seems to indicate that the producers, being controlled from one centre, are able to make a better bargain collectively than they could by selling individually. The average prices before the scheme started were much lower than they are now. It seems therefore that collective bargaining has been an advantage to the producers.

The three largest distributing agencies in London are United Dairies Co., with a capital of £1,000,000; Express Dairies Co., whose operations are not quite so large; and the Co-operative Wholesale Society. I visited each of these great companies and was given courteous answers to my inquiries. United Dairies serve about a million customers, but I did not obtain the exact numbers from the Express Co. or from the Wholesale Co. One reason why the Wholesale Co. could not give them is, because most of their distribution is made in bulk to their constituent Co-operative Societies and their customers call for the milk themselves. Refrigerating, bottling, and pasteurising plants are used by all of them, the latest being a very elaborate and costly plant owned by the United Dairies Co. I was shown over the whole of this establishment which was new and modelled on the most approved scientific principles. Both the United Daïries and the Express Co. advertise extensively (and expensively). The latter Company has a monthly Journal which is a most interesting publication. Both Companies spend very large sums in Research work and laboratory tests of every description. In a pamphlet issued by United Dairies in July, 1933, Professor Jameson, M.A., M.D., F.R.C.P., wrote a foreword in which he saïd "The fact that London has as safe a milk supply as any in the world is due in large measure to the efforts of certain big distributing companies—efforts which, incidentally, have not been without profit to the companies themselves. Directors are just as much concerned in doing what they can to improve the production of milk throughout the country as they are in distributing it in the best and safest manner to the public." Further on he remarked that "Progress is impossible without co-operation, and, as a member of the Public Health service, I am glad to have the opportunity of associating myself in this small way with what I believe to be a really helpful contribution to the solution of the problem."

The agitation for a pure milk supply in England has been going on for many years. Progressive steps have been taken at different times to improve the conditions of the industry, but it is no easy matter to get an army of 230,000 milk producers to work on the rigid methods suggested by the distributors and enforced by the Board. There are four essentials for pure milk insisted on by the distributing Companies of London, and in this way they are well supported by the Board.

1. Operators, when milking, must have clean dry hands.
2. Utensils must be well scoured and sterilised.
3. Safety: which means freedom from the presence of dangerous bacteria.
4. Reduction of diseases in dairy cattle.

It has been proved beyond any doubt that the principal contamination of milk occurs in the first stage of production. Some of the farmers neglect to wash and dry their hands before commencing to milk, and then place the fluid in containers that have not been properly scoured and sterilised. Bacteriological examinations in a multitude of cases and through a long period of years have disclosed the fact that it is in these early stages where the greatest damage is done. It has also proved that a milk which is unsatisfactory in the first stage, cannot be made satisfactory by pasteurisation.

Determined efforts have been and still are being made by distributors and the Board to educate the farmers. These efforts have not always been successful, but substantial improvements have been effected, and are still going on. It is difficult to convince a farmer that certain methods which he has been accustomed to for many years have got to be altered in the interests of the general health. He grows very indignant at being interfered with or advised, and too often insists on going his own way no matter how wrong it may be. To overcome this, the distributing Companies have induced model farmers to do the milking and use their own utensils at different places where it was known that milk was being produced under bad conditions. Tests of the milk produced in the old careless way have been compared with that produced under proper conditions, and the results are astonishing.

In the pamphlet previously mentioned, which was prepared by Mr. Ben Davies, Director of Laboratories, Processing and Inspection for United Dairies, the details of a most interesting experiment are fully described as follows:—

> ''Abundant experience, supported now by thousands of both pre-pasteurisation and post-pasteurisation bacteria plate counts, prove that with no more than a measure of regard for the merely domestic decencies, together with a simple and economical procedure for sterilising all utensils, it is possible to produce milk of consistently good bacteriological quality.
>
> In order to demonstrate finally that it is within the ability of the small producers to attain a satisfactory standard of bacterial quality, an experiment was initiated in connection with the supplies of one of the country creameries of United Dairies, where a system of premiums for the attainment of specified bacteriological standards has been in existence for some years. A number of the smaller producers were interested in the proposed experiment, none of whom had more than barely qualified for the bonus offered for the bacterial standard.
>
> The simple conditions laid down provided that the cows' udders should be clean, that milking should be effected with clean dry hands, that the first jet of fore milk should be discarded, and that all utensils should be sterilised. The steriliser provided for the equipment was merely a wooden box fitted over the farm copper, into which the various utensils, including the milk refrigerator, were placed for steaming after proper washing—a thermometer being provided to ensure that the boiling temperature was actually reached.
>
> The average bacterial count of the twelve farmers previous to the experiment in the month of February (1933) was 427,000 per cubic centimetre, with coliform organisms generally present in 1-1000 cubic centimetre. At the end of the experiment the average plate count of the milk as delivered at depot was less than 6,800 per cubic centimetre. In no less than nine of the twelve samples *b. coli* were absent even in one cubic centimetre and the average figures were superior to those obtained in the case of the Company's ''Grade A. Tuberculin Tested'' supplies for the same month. In the light of the facts contained in the foregoing pages, perhaps the most significant results lie in the post-pasteurisation figures. Previous to the experiment, the average bacteria count of the twelve farmers' supplies, after laboratory pasteurisation, was 27,000 per c.c. At the end of the period the supplies of no less than six individuals showed clean plates after pasteurisation. The average ''count'' of the whole twelve was merely 23 organisms per c.c. while the highest count in any one instance was 100 per c.c.
>
> An interesting corollary of the experiment arose when six of the twelve farmers, after their experience in clean milk production on their own farms, were asked to visit six other producers and undertake the milking on one afternoon, and thus to demonstrate what improvement could be effected with no special preparation whatever, other than the transfer of their own sterilised utensils, which they took with them. In the following table, the first column gives the normal bacteria count of each supply taken four days previous to the visitors' attendance—the result of whose work appears in the second column.

TABLE E.

Farm.	Owner.	Visitor.
	6/3/33.	10/3/33.
1	3,000,000	2,500
2	3,000,000	1,900
3	25,400	5,500
4	70,000	2,900
5	24,500	900
6	3,000,000	500

The plate count after pasteurisation in each case was :—

Farm.	Owner.	Visitor.
	6/3/33.	10/3/33.
1	80,000	100
2	100,000	200
3	600	100
4	3,900	100
5	1,000	300
6	200,000	100

At No. 2 Farm, the cows were milked by machinery. In this case half the herd was milked by the owner on his own machine, and half by the visitor's sterilised unit which was connected for the purpose. The results were as follows :—

	Owner.	Visitor.
Before pasteurisation	3,000,000	1,900
After pasteurisation	31,000	200

The methods of production which have to be followed in order to obtain such a standard universally do not depend on a preliminary course of instruction in elementary bacteriology to milk producers and their milkers. It is enough to lay down a few positive and dogmatic rules which cannot be departed from, and which the plain, hard-working folk who are responsible for a great proportion of the milk production of the country can easily practise and understand. These methods are dictated not only by science, but by regard for the common decencies which are properly expected to apply to the production and preparation of every article of human food. They comprise little of art and nothing of mystery.

If these rules are observed, the production of clean milk of good bacterial quality becomes automatic and even unavoidable. On the other hand, if they are neglected or relaxed, the laboratory tests which are proposed will very soon expose the fact and relegate the milk to that lower class to which it belongs, and which should receive payment at substantially lower rate. The production of dirty milk should be made too costly a luxury. Unclean milk should be definitely excluded from utilisation as human food.''

One very bad feature which arises from careless milking is that one negligent farmer, using unscoured and unsterilised utensils to pour his milk into, contaminates and spoils large quantities of pure milk. Elaborate tests have been made by emptying a few cans (churns) of carelessly drawn milk into one of the 3,000 gallon containers, and have proved that in a very few hours dangerous bacteria has developed in countless millions.

In the light of the above, perhaps it is not to be wondered at that thinking people in England should insist that this essential commodity should be produced in a clean, wholesome fashion. There is probably no known food subsance that is more susceptible to infection by dangerous germs than milk, and it is of the utmost importance that it should be kept free from contamination from the cow to the consumer. Notwithstanding these convincing tests, however, a rather large percentage of farmers become negligent at times—others are so by habit—and while the general results are noticeably improved there still remains much educational work to be done. When the milk reaches the great central depots numerous samples are taken and tested in four different ways before it goes into consumption. (One firm alone employs 102 qualified chemists for this purpose.) It is then cooled, and pasteurised by heating to a temperature of 145/6F. and is then passed over refrigerators ready for sale to the public. .

The conveyors from country to city have recently been very greatly improved. Enormous vessels, mostly holding up to 3,000 gallons for railway, and 1,200 gallons for motor transport, convey the milk to the chief distributing centres in London. These vessels, the inside of which is coated with glass, are so constructed that, even on the hottest day, the temperature of the milk does not rise more than one degree. Sometimes milk trucks are attached to express trains and the railway companies seem to do everything possible to facilitate the rapid transport of milk to the cities.

An important feature of the transport system is that from the time the milk is put into the glass-lined containers until it reaches the consumers who buy it in bottles, it does not come in contact with the amosphere or any deleterious matter. Those who buy milk from open containers are therefore not so safely supplied as those who buy the bottled article.

The practice of delivering milk in bottles appears to be increasing. No doubt this adds to the cost of distribution, but it is now known by most people that once the milk is exposed to the atmosphere, dangers of contamination are greatly increased. One firm supplied me with the following figures:—33 per cent. of their bottled milk trade is delivered in quarts, 55 per cent. in pints, 18 per cent. in half-pints, and 3 per cent. in one-third pints for schools. This firm's weekly output is 500,000 gallons of milk.

COST OF DISTRIBUTION.

Many complaints are made that the cost of distribution is far too high. The same complaint as regards milk is made all over the civilised world. The minimum retail prices fixed by the Board and now operating are 2s. 4d. per gallon, with a reduction of 4d. per gallon for quantities of more than one gallon, not exceeding four gallons delivered to one buyer at one place within twelve hours, and 6d. per gallon reduction for more than four gallons but not exceeding ten gallons. For delivery to local authorities, public bodies, voluntary hospitals, 1s. 6½d. per gallon. Sales beyond ten gallons are considered wholesale, and the profit on these would be about five per cent. The difference in the price received by the producer to that paid by the householder is nearly 1s. 4d. per gallon, but this is on the small deliveries only.

The Milk Board is making efforts to reduce the cost of distribution. It is true that the distributing companies are now making profits which they could not make before the Board took control of the industry, but they say that they cannot reduce their charges unless they eliminate two things. The first is the very costly and elaborate systems for guaranteeing pure milk before it is delivered to the consumer. The second is duplication in delivery. No one desires the abolition of the scientific safeguards that are now so extensively in use. Obviously that is unthinkable, and consequently attention is being paid to the second proposition.

During the Great War, in 1915 to be correct, the shortage of men became a potent factor in causing a number of reputable dairy firms in the Metropolis to amalgamate, thereby creating United Dairies Ltd., and it is claimed that this was the first step towards the rationalisation of London's milk service. Notwithstanding this operation, which meant the elimination of at least eleven distributors, there are still not less than a dozen, and probably more than twenty large distributing firms and a host of small ones. Assuming that there are no more than twelve it means that in any street of, say, 50 houses, there is a strong probability of every firm having customers in it. And not only that—which should be considered bad enough—but owing to the fact that so many people are now living in flats, it is a common thing to see a dozen milk carts calling at one house. This causes a tremendous amount of overlapping and creates expense in the way of overhead costs, superintendence, wages, horse or motor costs, wear and tear of vehicles, &c., &c. Then again, as customers are scattered, quite long distances have frequently to be traversed by a vehicle to supply a single customer. This also greatly adds to the cost of distribution. It is obvious that if the street of 50 houses were supplied by one or two vehicles and the same applied to the whole of London, the cost of distribution would be enormously decreased. This may be done by further amalgamation of firms, but it is unlikely that the Board itself will attempt to take over the retail distribution of milk, nor is it considered wise to attempt it. There is something to be said that if the whole of the distribution were carried out by one or even two firms, the lack of competition would bring many evils in its train. Still it is hoped that time and better organisation will gradually remove the waste that is constantly going on in the industry. Does it require another great war to lead or force traders and the general public to a realisation of this waste of time, money and effort?

CONSUMPTION.

The price has increased to the consumer by about 1d. per quart, but at the time of my inquiry there had been no change for nine months. It is to be noted in this connection that the Consumers' Committee reported to the Minister of Agriculture that retail prices had been "substantially increased" since the introduction of the scheme. If the increase is no more than 1d. per quart it should not be felt much by the consumer. The difference will be in the large quantities of milk delivered to hotels or restaurants, and places of that kind. It is obvious that 1d. per quart could not very well be added on to one-half and one-third pints of milk and as no retailer can charge more for his milk than the Board allows, it is difficult to see where the small consumer has any substantial ground for complaint. The costly and elaborate refinements of treatment described under "Distribution" have to be paid for by somebody. There is no escape from that. The new methods are expensive, but they are always clean. The old ones were cheap and usually dirty.

Taking the price which the farmers obtained last year, at 12.125d. (although the distributors pay more than that) the gross profit to them on small deliveries up to one gallon, works out at nearly 132 per cent. The gross profit on the larger deliveries is much less, but the net profit is probably more. It is this 132 per cent. gross profit about which so many complaints are made by the householder. He is apt to make comparisons between what he knows is the general profit made by retailers in other trades, which ranges from as low as 10 per cent. to as high as 33⅓ per cent., and he thinks and says very emphatically that distributors of milk are making exorbitant profits at 132 per cent. He forgets, or ignores, the outstanding fact that it nearly always takes less time and labour and general expense to deliver two or three gallons of milk at one place than it does to deliver the same number of pints at separate places. And again, the average householder does not realise the amount of close, hard-thought-out organisation and attention to detail that is required so that he shall receive his pint or two pints of milk in good time every morning.

The present price of 3½d. per pint for good clean milk cannot be considered excessive in comparison with other beverages, none of which have anything like the food value of milk, and in none is there the same expense in delivery. The householder is quite willing to take advantage of improved methods but grumbles at having to pay for them. This habit of mind is not peculiar to milk consumers.

As previously stated, great efforts are constantly made to educate the farmer and thereby induce him to produce an article of food that is clean and wholesome. Not only that, but he is often more or less heavily fined for breaches of the very stringent rules and regulations imposed by the Board and the Health Act, to say nothing of being engaged in an exacting occupation which often keeps him busy from 3 or 4 o'clock on Monday morning until 9 o'clock on the following Sunday night. He never gets too much time for sleep, and practically none for recreation. That may not apply so much to the larger dairymen who employ labour, but it is quite true as regards many thousands of small producers. So that, while the farmer is being drilled and educated and fined, it is not out of place to suggest that some education might well be administered to the consumers in the direction of having a little more kindly consideration for the other fellow.

GENERAL.

The Milk Marketing Scheme has certainly brought the industry into a better condition than it was before. Producers are getting better returns; distributors are making reasonable profits which they could not make before, and the public are getting cleaner and therefore more wholesome milk. But while this side of the picture is all to the good it is to some extent dependent on the Government grant which in the year which closed last May or thereabouts, amounted to £1,343,199. Even this large sum of money only increased the farmers' returns by ⅜d. per gallon, but it is difficult to see how much improvement in the industry could have been effected without it.

Three things, however, seem fairly certain. The first is that the farmers insist that they cannot produce milk at a lower price than they obtain now. The second is that the distributors declare that they cannot make their businesses pay if profits are reduced. The third is that if the Government grant is withdrawn, as indeed the Board is afraid it will be, the public will have to pay more for their milk. These are some of the many difficulties which beset the Board.

Granting that the general condition of the industry has improved, repercussions have occurred which are giving statesmen and the Milk Board grave anxiety. The most important of these is that while there was some over-production of milk before the present scheme was initiated, it has increased very largely since. The Chairman of the Board, speaking at the annual meeting held on 6th June last year on this aspect of the scheme, said, "The details of milk sales shown by our records disclose a definite tendency for production to increase. The average daily quantity of milk sold wholesale in this period has increased by nearly 18 per cent. over the corresponding amount last year. This increase was not fully anticipated, but, nevertheless, all supplies have been marketed."

As the Board is under contract to purchase all the milk produced by Class 1 of the producers in England and Wales, in addition to large quantities from Class 2, this increase is embarrassing it to a serious degree, and up to the time I left England no workable scheme had been discovered that would overcome the difficulty.

The causes of the rapid increase are not hard to discover. While no great profit can be made by the dairymen, even at the increased prices that the Board pays them for milk compared with those obtained under the haphazard methods of selling prior to the establishment of the Scheme, it was, and still is, better than anything else, and while the prices of other produce are low and can only be obtained by hard bargaining and sometimes losses by poor crops and bad debts, milk is a fixed price and the money is sure. Consequently, as many dairymen as could afford it have added another cow or two to their herds. Female calves that would have gone to the butcher became milkers, and the producers neglected other kinds of produce for the more certain one of milk production. This process is going on at an ever-increasing ratio, and seems likely to continue.

It may not be out of place at this stage to remark that a similar situation arose in France when some years ago that country prohibited the importation of wheat and fixed a payable price for the locally-grown product. In a very few years

France was overloaded with her own wheat, because her producers ceased planting crops for an uncertain market and devoted most, if not all, their attention to the crop that had a market assured to them.

Unless the British Milk Board can devise some means of overcoming this serious difficulty in addition to those they have put in operation up to the present time, it is certain, or at least highly probable, that a similar problem will arise in England as regards milk. It is difficult enough now and seems likely to get worse. Arising out of the desire of the farmers to produce milk in preference to other things, another problem has presented itself which does not affect the Board, but is a serious one for the landowners. A large percentage of the dairymen are tenant farmers, and since the Scheme came into operation they are constantly urging the landowners to erect more cow byres and other conveniences to accommodate a larger number of cattle. Under the very exacting local, as well as National Health Regulations, these structures are expensive, and as landowners, owing to excessive taxation and the general depression in agriculture, are often little if any better off than their tenants these demands are embarrassing them to a serious degree. They are afraid that the Scheme will break down of its own weight and they will be left with a lot of costly buildings on their hands that tenants will have no use for. Any suggestion that the tenant should pay more rent for the increased accommodation is immediately met with the reply that he can only pay the present rent with great difficulty, and really requires a few more cows to enable him to do it.

Efforts are being made to increase the consumption, and some success has been achieved and more may be expected in that direction. It is proved by statistics that not enough milk is consumed as food in the British Isles, and that there would be a higher standard of health if a larger use were made of it as such. School children are being supplied much more than ever before, and it is considered there is room for great expansion in this direction. During the year 1934-5 over 2,750,000 school children were supplied. Then very large quantities of milk are used in manufacturing certain commodities outside of food products.

But notwithstanding the efforts the Board is making to get more milk consumed, it is fully aware that the production will continue to increase faster than the consumption. It is now casting longing eyes on the butter, beef, and bacon trades, and great pressure is being exerted on Ministers and members of Parliament to impose import duties on these commodities in the interests of the British agriculturist. It is difficult to see how this pressure can be resisted for very long, and of course it has an important bearing on the export of Australian produce.

The British farmers argue, not unreasonably, that if England were to produce even 25 per cent. of the butter she now imports there might be no surplus of milk, and if a high enough import duty were placed on bacon and ham much of the milk that now embarrasses the Board would be fed to pigs and calves. Further still, a duty on beef would relieve the market of surplus cattle, and the farmer would be better off all round, and would not need to devote all his attention to milk production. It is scarcely to be expected that the British agriculturist will much longer consent to see his butter market so largely supplied from overseas. Britain is now a Protectionist country, and the people on the land will insist on their share of the policy the same or at least similar to that enjoyed by secondary industries. If they succeed in obtaining it, the butter trade will probably be one of the first to be reorganised and, if a substantial duty is imposed, there seems no reason to doubt but that enormous quantities of milk will thereby be absorbed and go into consumption as butter. This would be a great help to the Milk Board.

But it must be pointed out that increased consumption will mean increased production, and as the principal motive for increased production is the artificial stimulus of a fixed price and a certain return in money for the commodity, it seems highly probable that even if all of the aforementioned methods of increasing consumption are brought into operation the Board will be in the same difficulty as it is now.

There is one possible check on increase of production which may operate more successfully in the future than it has up to the present. It will have been noticed that the price of liquid milk was about 1s. 3d. per gallon and manufacturing milk from 3½d. to 4.92d. The practice is that the Board takes all the milk as "liquid," sells to the distributors such quantities as they require for the day, and the balance is surplus milk and sold to the manufacturer. The prices are then averaged out, and it follows that the more "surplus" milk there is the lower the average price will be. This may dawn on the farmers in time, and it is possible that the regional committees may endeavour to regulate the number of cows a farmer may keep, but whether such interference with recognised methods of production and trading will be tolerated remains to be seen.

All of the above economic facts are well known to those statesmen who were responsible for passing the Act under which the Board works, and they are well known to the Board also, but so far as I could gather, the industry, as before stated, was in a bad way, and it was felt that something should be attempted to improve it. The law of supply and demand has a rough and ready way of dealing with over-production of any commodity. Parliament in its wisdom decided to upset that natural law in connection with milk and substitute one of its own. Therefore the new system is an experiment, and must not be condemned before it has had a fair trial.

It is noteworthy that large numbers of the producers themselves are far from satisfied with the scheme. At the Board meeting held in London on 6th June, 1935, which was attended by about 500 farmers, very caustic and heated remarks were made, and some insisted that the whole scheme should be abandoned. The Chairman said that the prices in the present contract showed a substantial improvement, the average price for liquid milk being 1s. 3$^{1}/_{12}$d. per gallon compared with 1s. 2d. for the previous year. Even this statement did not appear to pacify the meeting at all, as several farmers from Devonshire denounced the Scheme, saying among other things that they were being strangled out of existence by it, while another farmer declared that "the scheme contains nothing for us but progressive ruin." Notwithstanding these complaints, however, there seems to be quite a large majority of farmers who, if they do not altogether like the Scheme, do not see anything at present to take its place, and are more or less agreeable for its continuance. No doubt many farmers object to the strict discipline they are subjected to, as it was stated by the General Manager that nearly £6,000 was due to the Board in fines which had not been collected. It is assumed that the multitude of rules and regulations imposed by the Board are difficult to carry out and being sometimes broken, penalties are inflicted which farmers either cannot or will not pay. But this accumulation of fines is not a healthy sign.

POLITICO-ECONOMIC ASPECT.

Some critics roundly condemn the Scheme and call it socialistic. Socialists, on the other hand, declare that there is very little about it that more than even distantly resembles their principles. To make it socialistic they say:—

1. That it ought to be controlled by the State.
2. That there ought to be equality of reward to all persons engaged in it.
3. That the profit if any should go to the State and not to private individuals.

The truth lies between these two extremes. The Scheme is really a mixture of socialistic and private trading, and might be more correctly described as enforced collectivism.

At the productive end of the industry, the farmers are individualists, working entirely on their own account, but restricted in the sale of nearly all of their milk produce to one purchaser, viz., the Milk Marketing Board. At the other end the distributors are public or co-operative companies or private individuals selling to whom they please, but restricted in their purchases as regards milk, to one seller, again the Milk Marketing Board. The Board fixes the price it will pay the farmer; the price at which it will sell to the distributor, and dictates the price at which the latter must sell to the public.

The justification for the Scheme is that no large capitalistic business in these times can be conducted without some elements of socialism (without being bound to an exact definition of that overworked word), and no socialistic business can be made to work successfully if at all without a large share of capitalism. The two things, although at daggers drawn in a general sense, shade into each other at certain points, and it may be that the British Milk Marketing Scheme is the happy medium to reconcile some at least of these conflicting methods of trading.

It may be quite safely asserted that if the Scheme were controlled by the State, and everyone engaged in it a civil servant, the result would be a disastrous failure.

On the other hand, the unrestrained methods of private trading as regards milk have proved unsatisfactory. There are some peculiar features about the milk trade that make it more susceptible to failure in private trading than any other, and this is accentuated in times of industrial crises. Very large numbers of people when thrown out of their usual occupation think they will work up a little milk round, and as they almost invariably start by cutting the local prices so as to get customers, it causes prices to be reduced to such an extent that no one can make the business pay. This, of course leads to unfair forms of competition, such as adulteration and careless, hurried methods of production and distribution. With such a delicate and highly sensitive substance as milk, such practices are not only improper, but are also very dangerous to public health.

In the main, it must have been the above reasons which caused the British Parliament to pass the Act under which the Milk Marketing Scheme was built up and is now operated. Having taken the plunge of initiating a radical change in the industry, it was wise in creating a separate board to control it. That there would be many embarrasing situations and awkward repercussions from such a departure was well known, but it was felt that the industry was in such a desperate condition that it could not be made worse by an experiment.

Up to the present time I think the experiment has been proved to have justified itself. The starting of such a gigantic scheme was a heavy task, and was bound to cause a great deal of friction. Many of the early troubles which arose have been removed, and if the Scheme is allowed to continue commonsense and experience will be the means of removing many more.

CONCLUSION.

The best features that I see in the scheme are:—

1. Unity of control.
2. Improvement in prices to the producer and distributor.
3. A great improvement in the quality of milk.
4. Possibility of more reasonable hours of labour in production.
5. Possibility of more rational distribution.
6. Had there been no Scheme only a small percentage of 2,750,000 school children would have been supplied with milk, and there is the certainty of extension in this direction.

The worst features are:—

1. The danger of over-production caused by the uneconomic stimulus of a fixed price which will, if not checked, gradually force down prices until the dairymen will be as badly off as before. If the prices are kept up vast quantities of milk will have to be thrown away.
2. The fact that farmers are already neglecting other forms of produce for the more profitable one of milk. This is causing increased importation of vegetables and other foodstuffs from overseas.
3. The Government subsidy which can only be excused as a temporary measure but which is likely to be regarded by the industry as an essential for all time.

ACTIVITIES AT ROSEWORTHY AGRICULTURAL COLLEGE, 1935-36.

PART II.—CROP ROTATIONS AND GRAIN HARVEST RESULTS.

[By ALLAN R. CALLAGHAN, D.Phil., B.Sc. (Oxon), B.Sc.Agr. (Syd.), (Principal), and O. BOWDEN, R.D.A. (Farm Superintendent).]

UTILISATION OF FARM FIELDS.

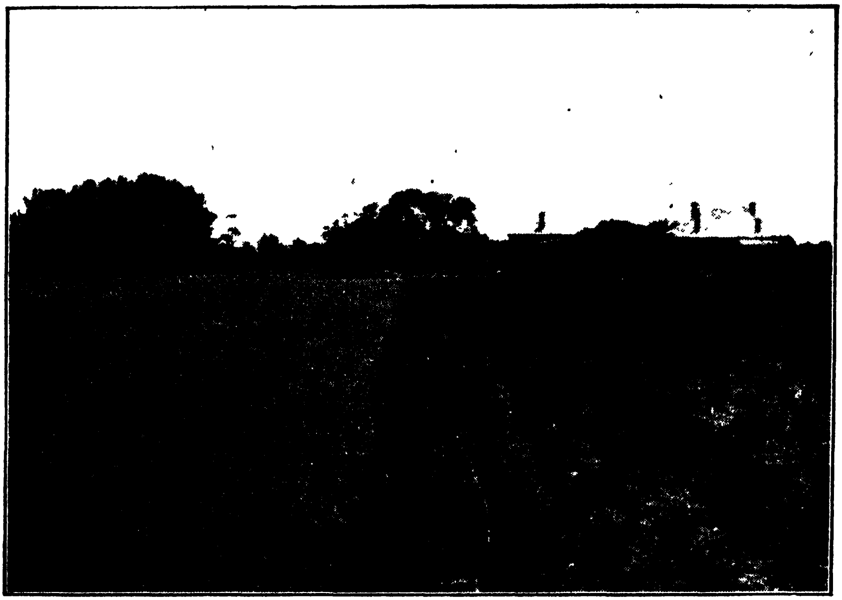
During the last few years every effort has been made to manage the College areas on the basis of a mixed farm in which wheat growing is regarded as the major project. Every consideration has been given and every precaution taken, to avoid the incipient evils of overcropping. To do this livestock numbers have been increased, the rotational system has been extended, and systematic conservation of fodder has been effected. Consequently these three aspects of the work on the College farm have received full report in these annual statements, and they are aspects of farming which might well be commended to the wheat growers of the State in general.

Reference to the accompanying maps, which cover the utilisation of fields over the last two years together with tentative treatments designed for the present year, will give some idea of how the rotational system has been extended. The paddocks Crouchs A and Crouchs B will serve as focal points for discussion. For three years prior to 1934 Crouchs A was rested from cultivation without any pasture treatment. For the same reasons Crouchs B has been rested since 1933, but it has been more fully utilised by livestock because of an excellent temporary pasture, part sown to lucerne and wimmera rye grass, and part to early subterranean clover and wimmera rye grass.

During the three years in which Crouchs A lay as ley land it received no attention. For the first two years some burr medic associated with barley grass made the paddock of some value for winter grazing. By the third year barley grass had taken complete possession and the field was practically worthless as a grazing proposition. The fact remains that the paddock was spared from the plough for three years, until in 1934 it was fallowed, and in 1935 sown to King's White wheat. The value of the rest was clearly shown in the crop which grew with vigour, excellent colour and evenness, a crop which gave no evidence that it suffered in any way from plant food deficiencies, and finally over the 62 acres harvested for grain gave an average yield of 36bush. per acre. It was the best crop on the farm, and its superiority can be largely attributed to the preceding history of the field.

This supplies some evidence at least to the theory that heavy yields may be expected from fields that have been given the benefit of a holiday from cultivation. Granted this, the object should be to rest the field in the most profitable manner possible. To do this, sowing of temporary pastures is strongly advocated. This advocacy is based on the experiences gained from the field Crouchs B which in 1933 was sown to 3lbs. wimmera rye grass and 2lbs. lucerne. On a small portion 3lbs. early subterranean clover were substituted for the lucerne. Every autumn since, the paddock has received 1cwt. superphosphate with the result that burr medic which is a volunteer species, has been a feature of the paddock each winter. On the area sown to lucerne, burr medic and wimmera rye grass have formed a splendid winter pasture and the lucerne has given regular autumn and late spring results, with an occasional very helpful growth during the summer. This is well shown in the accompanying illustration. The area under early subterranean clover has built up well and a good winter association of early subterranean clover and wimmera rye grass has developed, but in this area burr medic has not taken such possession. On the lucerne-wimmera area, the burr medic has been uniformly luxuriant over the last three years and this area of the field has been more productive than the area sown to early subterranean clover. This leads one to assert that where burr medic is a common volunteer, as on the College farm, it is doubtful whether it is economic to sow early subterranean clover. These remarks, it must be noted, are directed to the early form of subterranean clover and not to the late form. Its growth period is short, its production is considerably less and the feeding value of its aftermath does not appear to be as good as the late flowering form. Unfortunately the environment at College with its low rainfall definitely precludes the use of the late form, whereas the early form will grow and seed down readily every year.

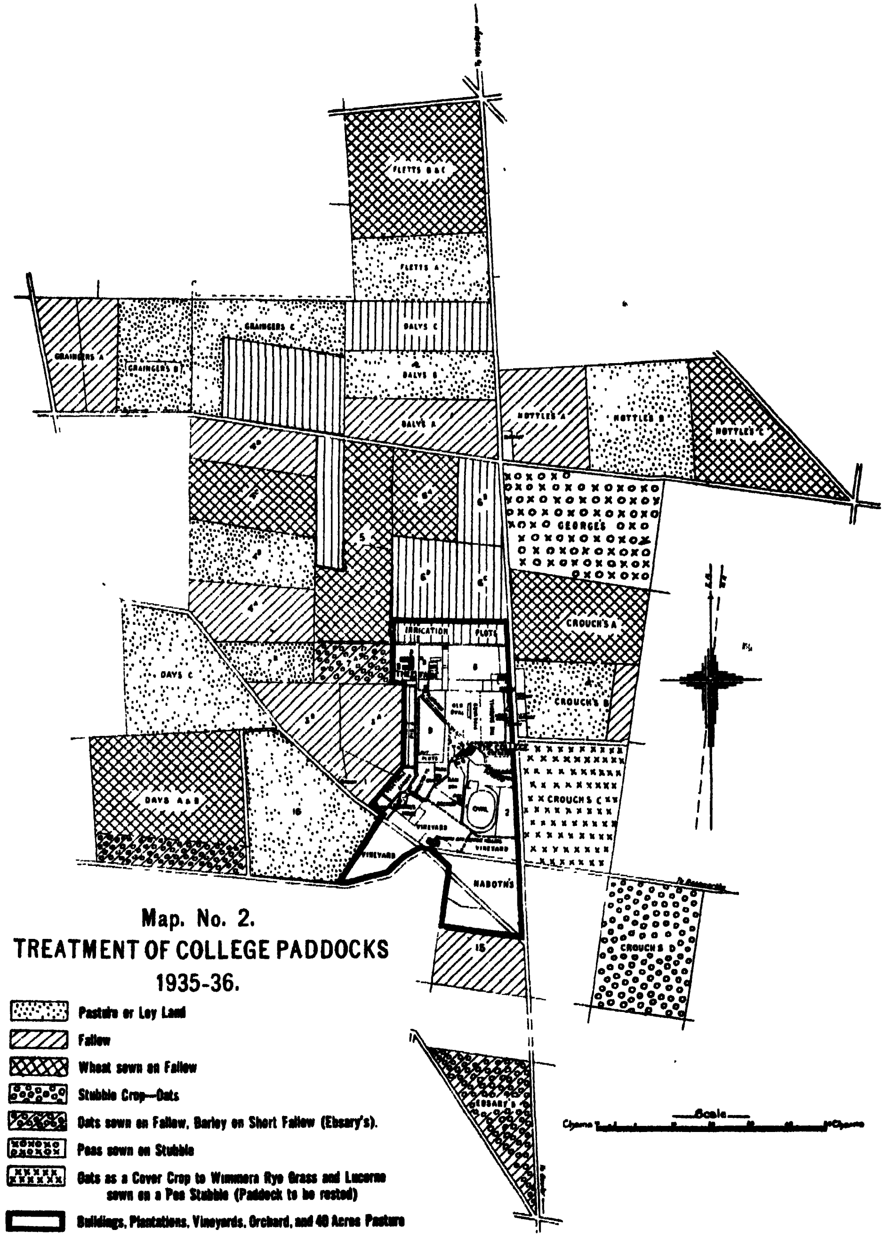
This field, Crouchs B, has just reached the zenith of its usefulness as a pasture and it is only with reluctance that it will be fallowed this year. The field is in its fourth year as pasture, and could well be spared from the plough for two more years, but unfortunately another factor has entered which makes it imperative to sacrifice the pasture, and that is the appearance of initial-cormule plants of Cape Tulip. This weed is not a bad weed on cultivated lands, for cultivation acts as a definite control, but on uncultivated lands it is a menace. Curiously enough its existence in this field was not suspected but the prolonged rest has given the weed a chance to make headway, and although to the average visitor it passes unnoticed, it is present in sufficient quantity to warrant attention. To allay its spread the paddock has been included in the fallow programme for the current year as shown in Map No. 3.



Lucerne in Crouch's B in January, 1936. The line demarcing the area sown to Lucerne and that sown to Early Subterranean Clover was very clearly defined following 175 points of rain early in January this year.

According to programme the next paddock to enter on holidays is Crouchs C. The following is the history of the paddock over the last four years:—1933, wheat; 1934, peas; 1935, oats for silage sown as a cover to 2lbs. wimmera rye grass and 3lbs. lucerne, which constitutes the pasture for 1936 and subsequent years. The establishment of wimmera rye grass by sowing it at the rate of 1 to 2lbs. with the preceding crop is the cheapest and most economical method of establishing this species, but only on the sandier lighter soils and with certain less rigorous oat varieties, has lucerne establishment on this basis been successful.

This year a further step in pasture establishment is being undertaken, and field No. 3 B, which was fallowed last year, will be sown to a mixture of lucerne,



Map. No. 2.
TREATMENT OF COLLEGE PADDOCKS
1935-36.

was delayed until the usual time in spite of the temptation offered by very favourable seed-bed conditions during April. Wheat seeding was not begun until the last few days of April, when a beginning was made with Ford, ideal seeding weather made it possible to sow all other varieties at the right time in accordance with their maturity; early in June, wheat seeding finished with King's White.

The weather during May proved almost ideal; although 1.42in. of rain were recorded for the month falls were light and separated by dry intervals. Rainfall for June, 1935, was below the average of 2.43in. for this month, but the 1.89in. received were very well distributed and of optimum usefulness. The year's rainfall to the end of June was only a few points above average, but its distribution had been unusually favourable, and by July there was a splendid showing of crops and pastures all over the farm. Feed growth was remarkable and all paddocks made up well, so that it was possible to keep the whole of Fletts A closed where self-sown cereal, enveloped with a mat of burr medic, subsequently developed to yield over five tons of volunteer growth to the acre when cut for silage in the spring.

Average rains were received in July and good falls were recorded early in August. A period at the end of August and early September with high temperatures of unseasonable character, accompanied by dry northerly winds, served the useful purpose of hardening the crops and steadied down growth which up till mid-August threatened to be over-sappy, approaching rankness. It was early in August, prior to the dry period referred to, that a local hailstorm of great severity passed over the south-western portions of the farm and caught a crop of Sword in Days A and B in its path. This crop was the pride of the place and the hail, striking it when it was just far enough advanced to suffer severely, cut it to pieces. The dry spell which followed gave it little opportunity for real recovery.

Good rains were very much needed all over the State when they were received with general satisfaction in September. These rains actually assured the wheat crop, and as the season advanced prospects improved. Excellent temperature and moisture conditions soon brought the crops into a forward condition and by the end of September all that was required was reasonable weather in October to assure good results.

Following a fairly long spell of dry weather after the mid-September rains October opened with a threat of bad conditions. For the first few days warm to hot temperatures were accompanied by strong northerly winds and dust. This rather upsetting prelude, however, was followed by a few light showers and cool conditions for some days, so that very little damage was done to the crops. By way of compensation for any such damage which may have accrued opportune rains of great value followed. The weather had unfolded a pleasant surprise; this applied to all parts of the State, for October recordings were above the average and they set free a feeling of optimism and satisfaction as far as harvest prospects were concerned.

As in 1934 finishing conditions were more favourable than usual. The only disturbing feature of the October weather was the effect of wind and rain on the oat crops. Two wind storms were experienced, and one was a heavy hot northerly blow which bent the oat crops over and in places broke the stems about 8in. from the ground. This reduced oat yields and made oat harvesting difficult.

MAP No. 3.

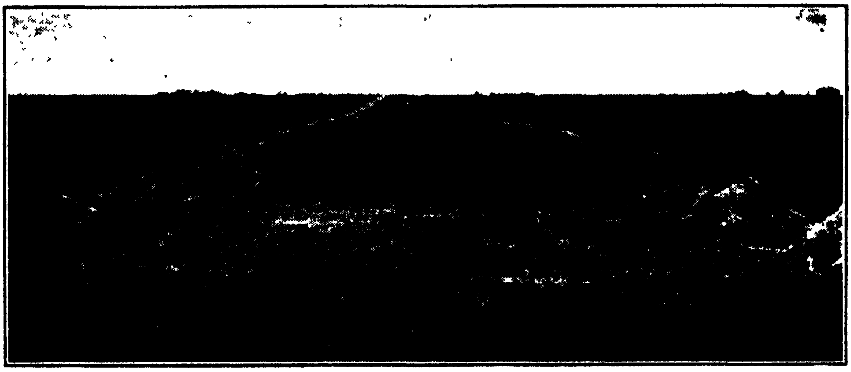
SUGGESTED TREATMENT OF COLLEGE PADDOCKS FOR 1936-37.

From the table it will be seen that the rainfall for the year was 18.49in. which is above the average of 17.40in. Similarly the seasonal rainfall represented by the period April to October inclusive was better than either 1933 or 1934. In both the latter years the rainfall was below average, so that better yields were expected for the 1935 season, and as stated in Part I. of this year's report, the average wheat yield, including the hail damaged crop, was a record for the College at 27bush. 59lbs., and the yield per inch of seasonal rainfall was 1bush. 55lbs.

WHEAT CROPS, 1935.

The areas sown to wheat were, as usual, fallowed land. Fallowing was begun the previous July when the fields were ploughed to a depth of 3in. Conditions were such that two cultivations were carried out with the rigid tyne machines before harvest, then following rains, two light workings with spring tyne implements were necessary, one in January, the other in March; the April rains were followed by a general rigid tyne cultivation, and by then all fallows were in a clean state of tilth ready for seeding.

Seeding was commenced in Fletts B and C with Ford at the end of April and beginning of May, followed by Ranee 4H in Nottles C, Dundee in No. 6A, Baringa in No. 5, Sword in Days A and B, Early Gluyas in No. 5, in that order and finished with King's White in Crouchs A during the first week in June.



Ford Wheat in Flett's B and C, 1935. The illustration shows the Stud Strip with the Pedigree Strips on either side, which in turn are guarded on the outside with Commercial Ford.

Seeding proceeded almost without interruption, the weather at no time interfered, and all seed beds were conducive to ready germination and good establishment. Growth was regular and vigorous right up until mid-August when a dry spell prevented excessive growth. Taking the season as a whole it was kind and favourable to the wheat crops, this applies especially to the weather experienced when the crops were finishing. Often very high temperatures and dust-laden northerly winds pay inopportune visits during the finishing phases of the crop, and while average conditions may prevail in other directions, such scorching and extremely drying days have serious consequences. The October weather of 1935 was free from such extremes, and crops were able to mature full, plump samples.

For a time stem rust was feared and actually appeared in mild form; the dry spell in August had effectively hardened crops and prevented rankness, this, with moving atmospheric conditions during October prevented the development of stem rust in epidemic form. The toll from Take-All in College crops was negligible, in fact very little disease of any consequence was noticed.

The calamity of the year from the point of view of the College wheat yields was the ruination of the crop of Sword by hail during August. The crop had made considerable upward growth and was in the last leaf stage when the storm was experienced. The stems were literally chopped off and to all intents and purposes the crop was ruined. Obviously a crop in such damaged condition should have been fed off, and it probably would have been more profitable to utilise it as cattle feed. This procedure was impossible as the crop was the only Sword wheat on the farm, and upon it the College supply of pure Sword seed was wholly dependent. For the sake of the pure seed programme the crop was allowed to take its chance. At least 75 per cent. of the crop had been cut and threshed to the ground where it withered and died. From the base of the damaged plants fresh shoots appeared later, but it was too late for them to mature good plump grain. The crop did well eventually to produce 14½bush. per acre, and probably 75 per cent. of the grain harvested was obtained from the second growth, and as this had such a short time in which to mature the sample was poor.

The best yield for the year was obtained from the old variety King's White. As mentioned earlier this crop was grown on Crouchs A which had previously been rested from cropping, so that all the credit cannot be given to the variety. It is interesting to note, however, that King's White, since its revival on the College farm, has yielded surprisingly well, in 1934 it yielded 33bush. 4lbs. from 40 acres and last year (1935) it headed the farm results with a yield of 36bush. 38lbs. from 62 acres. From the experiences of the last few seasons it appears that there is no very early maturing variety as suitable as King's White for growth under conditions similar to those pertaining at the College.

Wheat Yields from Farm Areas, 1935.

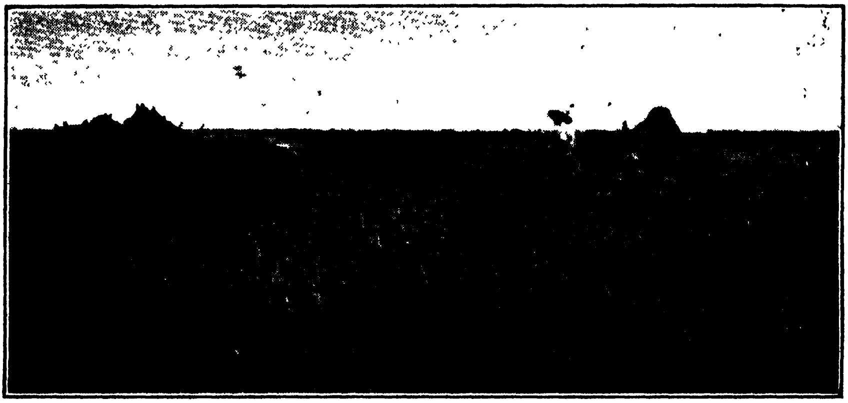
Variety.	Field.	Area in Acres.	Yield per Acre. Bush.	Yield per Acre. Lbs.
King's White	Crouchs A	62	36	38
Ranee 4H	Nottles C	37	30	8
Early Gluyas...	No. 5	23	29	21
Baringa	No. 5	16	28	45
Ford	Fletts B and C	50	27	3
Dundee...	No. 6A	22	23	36
Sword (damaged by hail)	Days A and B	34	14	25

Average yield of wheat, 27bush. 59lbs. per acre—a College record.
Average yield of wheat excluding the hail damaged Sword crop, 30bush. 44lbs. per acre.
Rainfall 1935, 18.49in.; April-October rainfall, 14.67in.
Yield per inch of seasonal rainfall, 1bush. 55lbs.

The variety Ranee 4H again gave good results. In 1934 this variety gave the highest yield on farm areas, namely 35bush. 43lbs. from 55 acres, last year from 37 acres, an average yield of 30bush. 8lbs. per acre was harvested. These yields are sufficient to indicate that the variety is suitable and capable of good results under College conditions; in this respect the variety is much superior to Free Gallipoli which was discarded because of its poor quality.

Of the other varieties Early Gluyas, Baringa and Ford gave satisfactory returns, but the returns from Dundee were rather disappointing. The crop was badly infested with wild oats and this infestation must have reduced the yield somewhat, but even so, the variety seems to prefer heavier soils, and on the light soils of the College farm it may never do as well as it has done in other districts. From localities where the season is longer and soil conditions heavier some very good reports concerning Dundee have been received; in view of these and its reputation as a better quality wheat the variety is being continued on the farm, and in this way the heavy demands for seed of the variety will be met.

Apart from the areas cited above smaller plots of Nawab, Florence and Huguenot were grown. In experiments from which large areas of hay are regularly cut the dual purpose variety Nawab has been found to be the most profitable variety. It yields well for both hay and grain, and for the last three seasons it has performed very creditably. Florence last year shattered rather badly. Shattering was particularly noticeable in many districts last season, but here at College most of the varieties on the farm held well, except Florence. A small area of Huguenot made dense and tall growth, yielding better than usual for this durum type. It stood 6ft. 6in. high and was a very showy crop; in spite of heavy winds it stood well, but many heads were broken off, a factor which must have reduced its ultimate yield considerably. Huguenot is grown to satisfy a small but regular demand for pure seed, as it is grown locally, mixed with oats, as a so-called shandy for hay.



A Student working a Harvester in a 30-bushel crop during the harvest of 1935.

OATS.

The chief objective on the College farm with oats is pure seed production. Farmers throughout the State are appreciating more and more the value of oats for grazing and as the best grain to store for general feed purposes for horses, sheep and cattle. Its place on the farm has definitely grown in importance, and the reflection of this interest is shown in the demand for seed oats from the College. In the past it has been quite impossible to fill the orders, such has been the demand,, and as inquiries are still in excess of the supply, greater attention must of necessity be paid to the crop.

Pure seed work with oats is complicated by the ubiquitous wild oats, and the ready way in which they cross naturally with cultivated oats under the conditions prevailing in the wheat belt areas of Australia. For this reason fallowing for pure seed purposes is really essential, and last season all oat varieties were sown on fallowed areas. Under the circumstances it was realised that heavy grazing of the young crop would be imperative and consequently the oat crops were heavily grazed during June and early July. The nature of the season was such, however, that very even and rapid recovery followed the grazing, and growth conditions were so propitious that exceptional late growth followed. To all appearances the crops would have stood up to normal conditions and some very heavy yields were anticipated, but the wind storms of October, already referred to, accompanied by rain did serious damage. The average yield obtained over the 100 acres of oats harvested for grain was 23bush. 29lbs. Although this yield is above the College mean yield for oats, it was disappointing, but is explained on the basis of wind damage, which lodged the crops and made harvesting very slow and difficult.

In view of the fact that accidental factors prejudiced the yields of some varieties more than others, the individual varietal yields are not tabulated. The best result of the season was from a small area of Fulghum, which yielded 37bush. 13lbs. This variety, curiously enough, has a reputation for weak straw and lodging, but the area was out of direct line of the most damaging wind storm and so it escaped to a large extent. The virtues of Fulghum as a grazing oat are unequalled when early feed and recovery power are taken into consideration. For sheep farmers who need an oat which will stand up to almost continuous grazing Fulghum is recommended. It is a risky oat to grow for hay or grain as it is liable to lodge and is ordinarily not a particularly heavy yielder, but its potentialities as a grazing oat are very great.

A yield of 28bush. 21lbs. was obtained from Mulga, while Early Kherson, over the largest area of any variety, acquitted itself very well with an average of over 26bush. per acre. This result was especially good considering that 30 acres of this variety were from Days A and B, which suffered the visitation of the hailstorm in August. This variety, Early Kherson, stands up better than most oats and can, as as rule, be relied upon in this regard. Other varieties grown in varying quantities were Guyra, Lachlan, Belar, New Zealand Cape and Algerian.

BARLEY.

On a farm where pure seed is a very important aspect of wheat growing, barley has to be carefully handled. For this reason all barley grown on the College farm is now concentrated in one paddock. This applies to experimental plots, plant-breeding rows and farm areas. Last year the field Ebsarys was devoted wholly to barley. This field has received special treatment over the last few years in an attempt to control wild oats, and following a wheat crop in 1933, which was badly infested, the paddock was combined with oats in 1934 and grazed right out. This enabled the field to be ploughed in October 1934 and to be treated as fallow over the summer months. It was brought into good condition by a light cultivation during the summer; this was followed by three cultivations in the autumn and before it was seeded in mid-July, 1935. Actually the desire to continue the efforts towards the control of wild oats prompted the unusual procedure of sowing barley on this short fallow. In 1934 the oats had been grazed very severely and none seeded before the ploughs covered all the remaining growth over in October. To utilise the field and yet not allow the wild oats to gain any ascendancy, it was decided to sow it as late as possible in the season. It was for this reason that barley was chosen. Being the most rapid maturing of all cereals, three autumn cultivations were permitted before it was time to sow. These workings were very successful in destroying wild oats which germinated in the autumn and early winter. This cleanliness was subsequently reflected in the barley crop, which, considering the heavy infestation of wild oats in the wheat crop of 1933 on this field, lent adequate support to the policy adopted.

The crop had just made a good covering of the field when the hailstorm passed over it, but being backward in growth it was not severely damaged, although it received a definite setback which it could ill afford, because of its late seeding. However, it eventually made up into a short but useful crop.

Barley Yields from Farm Areas, 1935.

Variety.	Field.	Area.	Average yield per Acre. bush.	lbs.
Prior	Ebsarys	26	33	42
Californian Cape	"	9	26	22
Roseworthey Oregan ..	"	7	23	19
Tunisian	"	3	20	10

Average yield per acre, 30bush. 16lbs.

The rate of seeding in all cases was 60lbs. per acre, and 1cwt. per acre of super-phosphate was used. The average yield was 30bush. 16lbs. per acre, Prior heading the varietal lists with a yield of 33bush. 42lbs. per acre.

PEAS.

Opportunity is again taken to emphasise the value of this crop on the farm. With livestock taking such a prominent part it is difficult to reason against the more extensive use of peas. True it is that farmers are appreciating the value of peas for summer feed, but the crop could be given more universal attention, at least in the better rainfall areas of the wheat belt. In the report on the College harvest returns for 1934 the value of the grazing aftermath was given prominence and an attempt was made to assess its actual worth. At the time it was considered the figures obtained were high but the really phenomenal results which were obtained last year make one all the more anxious to acquaint farmers who are unaware of the value of the crop with the details which can hardly fail to convince.

Dismissing, for the time being, the actual returns from grain harvested and aftermath grazed, the pea crop is one which should be sponsored by every farmer anxious to increase the efficiency of his paddock rotations. There is no crop suitable for the wheat belt which will thrive so well on soil low in nitrogen. Given a liberal supply of phosphate, and a clean seedbed, the crop will flourish. It can be seeded late, about the end of June or early July after all other seeding, with the possible exception of barley, has finished. In this way thorough destruction of all autumn germinating weeds is effected, the late workings even proving effective on soursobs. Peas enrich the soil in nitrogen because of the properties of nitrogen fixation which their root systems possess in common with other leguminous plants. Then, in addition, droppings from stock during the feeding off of haulms and general crop aftermath have an appreciable influence for good on the soil. Taking all these agricultural features into consideration as well as the direct monetary returns the crop offers, it is difficult to see how the crop can be omitted from the rotation where climatic conditions make its growth possible.

The whole of the paddock, Georges, in all 110 acres, was sown to peas in 1935. In 1934 the field grew wheat. This stubble was burnt off in the autumn and the paddock kept grazed until early in May when it was ploughed to a shallow depth. It was subsequently harrowed and cultivated at the end of May, then cultivated and drilled to 120lbs. of White Brunswick peas sown with 1½cwts. superphosphate early in June. The paddock was then immediately harrowed and cultipacked.

This treatment was effective in killing soursobs and other weeds, consequently the crop made excellent headway and at flowering time, from the outside, appeared to be perfectly clean. Field notes indicate, however, that early in August summer weeds germinated profusely, especially wire weed. By the time the crop was ripe for harvest the wire weed and other summer plants had reached robust proportions. This certainly delayed and made harvesting difficult. The consequence was that a fairly large proportion of the crop was left on the ground. Even so an average yield of 15bush. per acre was obtained and under the circumstances was considered quite satisfactory.

The peas left behind, together with the haulms and abundant wire weed, provided a field of summer feed which would be difficult to equal in this environment. At its best the paddock resembled a lucerne field, the wire weed seemed to thrive especially well, and the paddock was undoubtedly worthy of the envious comments made by visitors who saw it. The grazing results obtained bear this out; for the period January to April inclusive the field carried 3½ sheep per acre. Specifically, 40,911 sheep days of grazing were obtained for the four months, and this is the equivalent of slightly more than 1 sheep per acre per annum for the 110 acres of the paddock.

In view of the nature of the feed and the rapid improvement in the stock depastured on it, an allowance of 3d. per sheep per week does not seem excessive in assessing the grazing value. Granted this and the returns from the paddock can be quoted as worth approximately £413 for the season, or an equivalent of about £3 14s. per acre, based on 1,704bush. of peas at 4s. per bushel making £340, and the grazing of 365 sheep at 3d. per week for 16 weeks making £73. These results were undoubtedly helped by rain in January which freshened up the wire weed, but this fact does not detract in any way from them, as they offer convincing evidence of the direct usefulness of the pea crop on the farm.

THE AGRICULTURE OF NEW ZEALAND.

[By R. C. Scott, Chief Agricultural Instructor.]

(Continued from page 1303.)

DAIRYING IN NEW ZEALAND.

Dairying in New Zealand is practically of equal importance to the frozen meat and sheep-raising industries of that country. Ninety-two per cent. of the total exports are made up by pastoral products, and of these the dairying industry, including butter, cheese, dried and preserved milk and casein can be credited with 45 per cent. of the total value. The principal items as shown in the 1933 statistics are:—Butter, £11,649,000; frozen meat, £9,846,000; wool, £7,422,000; cheese, £4,766,000. From the above figures some idea of the importance of the dairying industry will be gained, whilst as further evidence there is the fact that of the cheese imported into the United Kingdom in the year 1933, 67.7 per cent. was obtained from New Zealand, whilst Canada, which occupied second position, only forwarded 20.7 per cent. Again, in the matter of the importation of butter into the United Kingdom in the same year, 28.5 per cent. and 28.4 per cent. were secured from the countries of Denmark and New Zealand respectively, whilst Australia occupied third place with 19.2 per cent. It is this development of the dairying industry which has been of great economic importance to the Dominion in recent years.

A dairy herd on a Waihati farm. The Jersey is the most popular breed.

DISTRICTS.

Dairying is mainly practised in the North Island, where approximately 80 per cent. of the dairy products of the Dominion are obtained. The chief districts are Taranaki and Auckland. The principal town in the first-named area is New Plymouth, with Auckland and Hamilton the important places in the latter. Whilst these may be described as the principal areas, dairying is carried out on all the lower lands of the North Island.

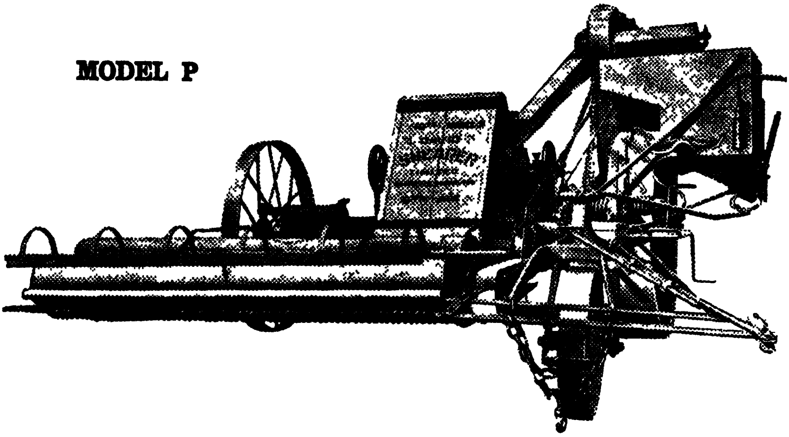
In the South Island the districts are scattered, but are more concentrated in the vicinity of Christchurch and the fertile lands near Nelson. The main points governing the selection of land suitable for dairying are relatively low altitudes and country preferably of an undulating nature, mild temperatures, fertile soils, together with sufficient and evenly distributed annual rainfall. This even distribution means not only fairly regular rainfall from month to month, but also

Speed up your harvesting this season with

The New Light-Draught

"SHEARER" 10ft. HARVESTER

MODEL P

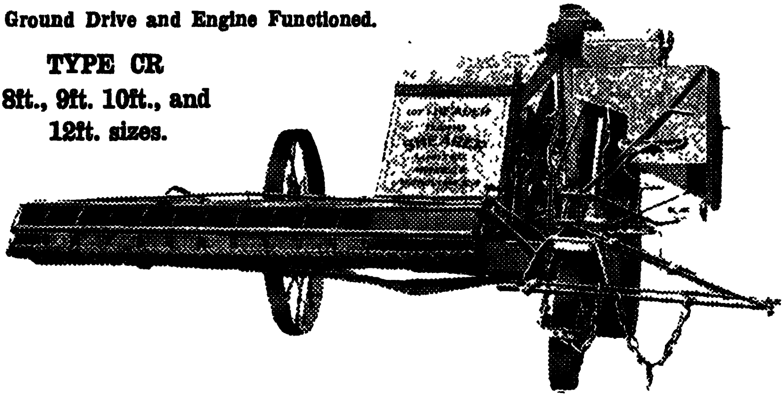


We are proud to offer this newly designed 10ft. Harvester—a large number of these machines were sold during the past two seasons and we have received excellent reports. Side draught has been eliminated. The machine has large capacity throughout. Renolds roller chain drives are used.

The 1936 "SHEARER" HEADER

Ground Drive and Engine Functioned.

TYPE CR
8ft., 9ft. 10ft., and
12ft. sizes.



1936 Improvements include roller bearings in main wheels, steel chains in elevators, longer walkers, release gear on return elevator, fan driven by roller chain, step riddle. These improvements with the large capacity of the machine assures that any condition of crop can be reaped with ease. The 1936 machine is very light in draught.

Please write for illustrated catalogues and "Facts from Fellow-farmers."

DAVID SHEARER Ltd, Mannum, S.A.

C.O.R
BRITISH QUALITY PRODUCTS

A Great National Institution

NINE years of rapid growth and progress and the C.O.R to-day is established as a great national institution servicing Australia's defence forces, mails, railways, other government services, overseas and coastal shipping, industrial concerns, primary producers and private motorists throughout the Commonwealth.

The C.O.R has secured for Australia permanent supplies of petroleum products, established the first refinery in Australia for the treatment of imported crude oil, pioneered the introduction of high anti-knock coloured and treated petrol, and was the first to distribute petrol scientifically blended with Australian benzol on a National scale. Its kerosenes, fuel and Diesel oils are efficiently servicing primary producers, shipping and secondary industries. Its latest service to the Nation is an intensive search for oil in Australia now being conducted by leading geologists.

Because the C.O.R has rigidly adhered to the highest standards of quality the demand for its products is establishing new records month after month. A continuance of public support will enable the C.O.R to extend its usefulness and wide range of services to the Nation. Do your part in helping to build this valuable National institution by using the undermentioned C.O.R quality products.

even distribution throughout each month. As the greater portion of the North Island receives from 30in. to 60in. annual rainfall, whereas on the lower levels of the South Island the normal precipitation is between 20in. and 35in., it follows that the most extensive areas of suitable dairying land are to be found in the North Island.

FARMS.

The greatest proportion of dairying is done on specialised dairy farms, and it has been estimated that about 5,000,000 acres are devoted to this industry. The herds total 75,000, with an average size of 24 cows, but on the other hand 45 per cent. contain 20 or more cows and, therefore, the main dairies may be included in this section. Further, from the point of view of production over 80 per cent. of the total butterfat is secured from what may be described as the larger dairies.

As a rule the holdings are small, and from an investigation into the size of farms in eight typical dairying counties it has been shown that the average dairy farm in New Zealand is about 120 acres in area. In the Taranaki district the mean of 1,030 farms indicated that the average area was 107 acres, and these carried 45 cattle per 100 acres, together with 13 sheep. Similar figures for 1,612 farms in Waikato were 198 acres, 37 cattle and 30 sheep, whilst 456 farms in Waimate West were 111 acres in area and carried 63 cattle and 8 sheep per 100 acres.

Sown pastures are always associated with dairying, and the most striking feature about such pastures is the density of the herbage. Little bare ground is to be seen, and the quantity of feed per unit of area is very great. The main pasture mixture for districts subject to frost and hard winter conditions is a good balance of Perennial Rye Grass and White Clover, whereas in those localities where the winter is not so severe Paspalum is frequently associated with these two varieties. Other fodders such as Cocksfoot, Crested Dog's Tail, and Red Clover are often found in the pasture mixture, but those named are the dominant types.

Roots and other crops do not play an important part on dairy farms, and owners depend upon proper management of the permanent pastures to supply feed requirements. On most farms the permanent pasture is top dressed each season. The quantity applied is not limited, and a mean of a number of high-producing farms was 3cwt. of superphosphate per acre. It follows that if 3cwt. is the average dressing, there are many cases where the application is much heavier, and dressings of up to 6cwt. to 7cwt. of superphosphate to the acre are not uncommon. The usual time of adding the fertiliser to the land is autumn (April or May), although late winter or early spring (August or September) is the popular period with many.

When heavy dressings are being given, the field is usually treated both in autumn and spring. Practically the whole of the top-dressing is in the form of superphosphate. Lime is also applied as a soil amendment, the usual quantity being 5cwt. to the acre in alternate years. Of late years there has been a steady advance toward the subdivision of farms, and the provision of smaller fields. Instances of 25 to 30 paddocks are quite common. On the best farms the aim is to have the fields of such size that the feed can be eaten down in two to three days, which means stocking at the rate of 12 to 18 cows to the acre. The grass growth is permitted to attain a height of 3in. to 4in., and is then stocked heavily for a short period so that the maximum consumption of nutritious fodder is secured before the pasture is fouled. The young and dry cattle follow the milkers, and if these are insufficient to control the grazing, sheep are sometimes used. After removal of this follow-up stock, the paddock is often mowed to cut off the roughage, harrowed to spread the droppings, manured if necessary, and shut up. During the spring when growth is rapid and the feed may get beyond the best stage for grazing, portion of the area is set aside and harvested as ensilage or hay. Ensilage is the more popular form of conserving fodder, and in 1933-34 over 500,000 acres were cut for ensilage or hay.

PRODUCTION.

In 1933-34 the number of cows in milk in the Dominion was 1,933,000, and on a butterfat basis the yield per cow was 220.8lbs. There has been a substantial improvement in this direction over the past 13 years, as in 1920-21 the return per cow was 154.24lbs. In the main dairies the average production per head is from 250lbs. to 275lbs. per cow, whilst the best attain a total of 375lbs. and over. However, correct grassland management and high-producing cows go hand in hand in the raising of returns, and the production is probably best recorded on an acre basis. The average production of all land devoted to dairying has been estimated at 80lbs. of butterfat per acre. On the other hand returns from 550 farms have been collected by the Department of Agriculture in New Zealand, and this survey shows that the average butterfat return from the specialised dairy farms lies between 125lbs. and 150lbs. per acre. If we take the records of the six best farms included in these particulars, it is found that over 250lbs. of butterfat per acre are secured. It is also interesting to note that the highest acreage production was obtained from the smallest holdings. The mean area of the six farms referred to was 85.6 acres, each carrying 74.38 cows, representing a grazing capacity of 0.869 of a cow per acre per annum.

[From *The New Zealand Farmer.*]

The Aberdeen Angus cattle are being largely used for the export trade in chilled beef.

These figures give some idea of the high production of some of the best dairies, and the good general average acre yield of butterfat.

BREEDS OF DAIRY CATTLE.

The latest statistical returns regarding the breeds of dairy cattle in the Dominion were issued in 1928, and in that year the position was as follows:—

	Per Cent.
Jersey	63.3
Milking Shorthorn	22.1
Friesian	12.0
Ayrshire	2.6

From the above it will be seen that the dairy herds consist mainly of Jersey or grade Jersey animals. No particulars have been collected since 1928, but it is certain that the lean toward the Jersey breed has increased since that year at the general expense of the other three breeds, and it is probable that at the present time the number of Jerseys or grade Jerseys approaches 80 per cent. of the total dairy cattle.

The reasons for this breed being so popular are that as it is one of the smaller types the landowner is able to carry a larger number of effective milking cows per acre than would otherwise be the case; he is utilising a breed with high butterfat production; and finally, he is adopting a class of cow which is very early maturing. Whilst many of the herds may be regarded as pure Jerseys—since the dash of Shorthorn or other blood is several generations distant—it was particularly noticeable that almost invariably such herds were headed by a really high-class bull, and in that way a general raising of the standard was being effected.

HERD TESTING.

Herd testing is generally adopted by dairy farmers throughout New Zealand, and 287,000 cows were under test in 1933-34. It was first developed in 1910, and since that year has been increasingly availed of by dairymen. The culling out of inferior stock and the competition following such movement has had good effect in bringing about greater effort, and consequently in raising the standard of production in herds.

Facilities are available for testing both pure, crossbred, and grade cows, and at the present time the cost ranges between 3s. and 4s. per cow.

MARKETING.

In 1933-34 there were 210 butter factories and 274 cheese factories in the Dominion, whilst 45 carried a dual butter and cheese manufacturing plant.

In the earlier days the factories were small, as it was customary to erect a factory for 250 cows, but to-day these smaller factories have been largely absorbed by larger concerns. In view of the number of factories, little of the cream or milk has to be transported over long distances, and an average radius of collection for 60 factories whose areas were investigated by the New Zealand Department of Agriculture was 28 miles, or an approximate district of 175 square miles. Of course, some of the dairy produce has to be transported to a greater distance, and there are instances of cream being railed 200 miles to the factory.

The road and rail faciities for the collection of produce from the farms are really good, and in the main areas it is usually picked up daily, and even in districts situated further from the factory it is seldom less than every second day that the produce is collected.

As a rule, transport of cream is arranged by the butter factory, whilst the delivery of milk to the cheese factories is almost entirely the responsibility of individual farmers. Overlapping in the collection of cream occurs in the same way as in South Australia, and although it is claimed that this competition is to the advantage of the industry, the Dairy Commission of 1934 estimated in their report that there was an annual loss of £150,000 because of overlapping. On the other hand, new regulations gazetted in 1934 made it illegal for a supplier of cream or milk to a factory to transfer his supply to another factory during the same season without first obtaining the consent in writing of the owner or manager of that factory. The dairy farmer is paid on a butterfat basis whether supplying to a cheese or butter factory, and the average prices received of recent years were as follows:—

	Per Lb. d.
1921-30	17
1930-31	12
1931-32	11
1932-33	9
1933-34	9
1934-35	10 (estimated)

In 1920-21 there was a guaranteed price of 30d. per lb. for butterfat, but this only existed for the one season, and in the following year the average price dropped to 14½d. per lb.

The high prices had the effect of increasing land values, and with the steady deflation which followed, the position became serious, particularly for those men on newly-acquired farms which were not in full production. However, the circumstances that arose and the necessity for meeting the obligations incurred have, to a certain extent, been responsible for greater efficiency in the dairying industry. Nevertheless, whilst dairying land in New Zealand is of high capital value to-day, all of it was not purchased in the boom period. The result is that in such cases it is only an assumed value so far as these owners are concerned. The position regarding the sale of milk for human consumption is much the same as in South Australia. The exception occurs in the city of Wellington, where the municipality has a partial monopoly. This monopoly is only partial, as when the regulations were brought into force all dairymen situated within two miles of the city boundary were permitted to sell milk within the city. These men deliver about one-third of the requirements of Wellington, and the remainder is supplied by the Municipal Milk Department. The municipal lorries pick up the milk over a distance of 30 miles, but in the summer time none is accepted further than 20 miles from the depot. On arrival the milk is immediately pasteurised and bottled. It is delivered in the metropolitan area by the municipality, and the city is divided into blocks to prevent overlapping. All payment is made by means of tokens which can be purchased from the Department. The usual practice is for the house owner to place the required number of tokens in the empty bottle to meet the cost of the milk for that day. It is claimed that by the use of tokens bad debts are avoided. Under this scheme the producer obtains 10d. per gallon for his milk, which, after pasteurising and bottling, is retailed at 1s. 8d. per gallon. Conse-

quently, the consumer does not obtain his requirements cheaper than elsewhere, but, on the other hand, it is generally admitted that there is an improvement in the quality supplied.

A small source of revenue for dairymen which has been built up since 1927 is the sale of vealer calves. This is known as the "Bobby Calf Trade." Prior to 1927 it was customary to slaughter all surplus calves for their skins, but with the development of this trade the dairyman obtains more money for his surplus calf and with less labour. The calves are treated at the freezing works, boned, and packed as boneless veal. On the average each yields about 18lbs. of meat for which there is quite a good market overseas. The trade is governed by regulation, which requires the calf to be at least five days old and reasonably matured. As a rule, the animal is about this age when taken to the freezers, and a fair average price is approximately 7s. per head. As an illustration of the advancement made in this trade there is the fact that in 1933 614,000 calves were treated, whilst in 1934 the number had increased to 954,000.

CO-OPERATION.

Co-operation in the dairy industry is very strong, and practically all the factories, both butter and cheese, are co-operative concerns. The New Zealand Co-operative Dairy Company is claimed to be the largest co-operative company in the world. It has 8,000 members, and maintains 16 butter and 18 cheese factories, one casein, and one dried milk factory. Alone this company handles about 30 per cent. of the dairy produce exported from New Zealand. As a matter of fact, the great bulk of the dairy exports is consigned by co-operative companies, and in 1934 only 8,000 tons of butter and 2,000 tons of cheese were sent overseas by proprietary firms, comparatively with 132,000 and 98,000 tons respectively by co-operative companies.

ADVERTISING.

From levies of 3/64d. per lb. for butter exported and 3/128d. per lb. for cheese, exported, the New Zealand Dairy Produce Control Board obtains its funds. The gross amount collected in 1934 by these means was £81,037. The Board has been effective in bringing about a substantial reduction in freight and insurance rates in recent years, and also in conducting an extensive advertising campaign throughout the United Kingdom. An energetic advertising drive in favour of New Zealand dairy produce was inaugurated in July, 1933, and in seven months £120,000 were spent, whilst in the following year £41,438 were utilised in this way. The result has been that New Zealand butter and cheese are kept prominently before the consuming public, and it was noticeable that any article exported was always clearly labelled with the name "NEW ZEALAND" conspicuously displayed.

BEEF CATTLE IN NEW ZEALAND.

Within recent years the difficulties in connection with the successful shipment of chilled beef have been largely overcome and consequently the industry is more important that was previously the case. Beef is one article which has a greater local consumption than export trade and only about a third of the beef produced is sent overseas. Beef is grown on both pastoral and dairying properties, but that from the latter is largely obtained from steers, surplus cows and a few culled heifers, with the result that this meat is generally tinned and preserved rather than sold fresh.

The hills country is best suited for the raising of cattle, and large numbers bred in these areas are purchased as stores and fattened on the plains. Thus on fat lamb farms and specially swampy lands which are not altogether suitable for milk cows the topping up of beef animals is a regular part of the farming operations.

On the plains a few cattle are generally kept to control the pasture, clean up the ranker feed and maintain the herbage in the best condition for maximum benefit.

In 1934 there were approximately 1,600,000 beef cattle in New Zealand, and 159,233 carcasses were exported overseas.

No statistics regarding the breeds have been collected since 1928, but in that year the distribution of pure bred animals was as follows:—

Aberdeen Angus	4,269
Hereford	4,210
Beef Shorthorn	2,620
Other breeds	116

[From *The New Zealand Farmer*.

Herefords on a North Island farm near Masterton.

Therefore, eight years ago the Aberdeen Angus and Hereford were approximately equal in numbers, but since that time the first-named breed has gained ground at the expense of both the Hereford and Beef Shorthorn, but mainly at the expense of the latter, and it is probable that to-day the majority of beef cattle in New Zealand are either Aberdeen Angus or Aberdeen Angus crossbred.

Their popularity is due to the fact that they thrive in steep and difficult hilly country, they yielded an excellent carcass and either as a pure breed or when crossed with other cattle produce polled, early maturing progeny well suited to the requirements of the country.

The Hereford is regarded with favour in certain districts, as it is claimed that this breed has great capacity to recover from any check due to cold wintry conditions, and in this respect both the Aberdeen Angus and Hereford animals are better than the Shorthorn.

SHEEP IN NEW ZEALAND.

The climate of New Zealand is well suited to the raising of sheep, whilst the perfection of refrigerating machinery altered the whole position so far as the industry was concerned. Prior to improvement in this direction practically the only exports were wool, tallow, and hides, but to-day with the export of frozen carcasses, sheep raising is the most important primary industry, and in 1934 the value of the products exceeded £23,000,000.

Some idea of the extent of the sheep industry in the Dominion can be gained from the following statistics:—

Sheep Industry Season, 1934.

Total number of sheep	28,649,038
Lambs exported	8,719,301
Mutton exported	2,010,084
Lamb consumed locally	106,121
Mutton consumed locally	1,546,050
Wool (lbs.)	300,500,000
Value Meat	£8,757,144
Value Wool and Skins	£14,700,663

DISTRIBUTION.

Sheep are well distributed throughout both Islands, the actual numbers for each being approximately equal.

Where the rainfall is fairly high and the altitude not too great dairying is mainly practised and sheep are pushed back to the higher levels, but on the lower lands where the rainfall is less sheep are chiefly kept, and this class of country is the main fattening area for export lambs. However, practically all farms carry some sheep, even if dairying is the principal source of revenue, and they are generally distributed throughout the occupied area of the Dominion, with the greatest population in the Hawke's Bay and Wellington districts.

BREEDS.

On high country in the South Island, where snow falls regularly each season, and the pasture is of a poorer type than elsewhere, it is necessary to keep the most hardy breed of sheep. Under such circumstances the Merino is kept because of the extra value of the wool. Consequently, it is found that in the South Island Merinos comprise 9 per cent. of the total number, but on the other hand only 0.2 per cent. of the sheep in the North Island are of this breed. The Romney Marsh is of the greatest importance in both Islands followed by the Corriedale and Southdown breeds. The sheep may be classified into two groups, namely registered and other pure breeds, and cross and half-breds. The latter group represents about 80 per cent. of the sheep of New Zealand, and in 1934 there were 22,760,901 of this type, comparatively with 5,888,137 pure bred animals.

A Crossbred is any long woolled sheep of mixed breeding, whilst a half-bred is a straight cross between a Merino and a Long wool. However, the latter type is not very numerous, totalling 2,199,542.

The Crossbred has been built up from the original Merinos, since the latter breed did not thrive in the heavy rainfall districts. In the early days English Leicester, Lincoln, Romney Marsh, and a few Cheviots were used, and it was the systematic inbreeding of the Merino-Longwool half-bred which resulted in the production of the Corriedale. However, in the development of the present-day Crossbred the Leicester was the first to drop out of favour, whilst with the poor demand for strong wool the Lincoln lost ground, leaving the mating chiefly to Romney Marsh

[*Photo. New Zealand Tourist Bureau.*

rams. Therefore the New Zealand Crossbred to-day is principally of Romney Marsh blood, although in many cases Lincolns, Leicesters and Merinos may be included amongst their ancestors.

Attention has been directed toward conformation rather than quality of wool and there is considerable variation in this connection. The average count is from 46 to 50 whilst that from the half-breds reaches a maximum of 56.

The percentages of the different breeds of pure bred sheep in New Zealand are:—

Romney Marsh	52
Corriedale	22
Merino	18
Southdown	5
English Leicester	1
Border Leicester	1
Lincoln Ryeland Shropshire	1
Total	100

From the above figures it will be seen that the Romney Marsh is far and away the most important pure breed in New Zealand, and has attained that position because of its suitability to the climate and resistance to foot rot. The majority of stud flocks are Romneys, and the flock rams from these are used as sires in the production of crossbred ewes which form the basis of the fat lamb flocks.

A really good class animal has been built up possessing a well-shaped body and with fairly fine bone. They are somewhat variable in the wool, but nowadays more attention is being paid to this question, and general improvement in the near future is anticipated.

The Corriedale is also fairly popular and when mated with the coarser Crossbred yields progeny with finer wool than their mothers, whilst at the same time there is no loss in conformation. As has been said, the Merino is confined to the colder and poorer pasture areas of the Southland because of its suitability to such conditions, whilst the Southdown is practically the only mutton breed used.

It follows, therefore, that breeds used for the production of the export lamb in New Zealand are almost entirely the Southdown as the sire, and the Crossbred or Halfbred as the dam.

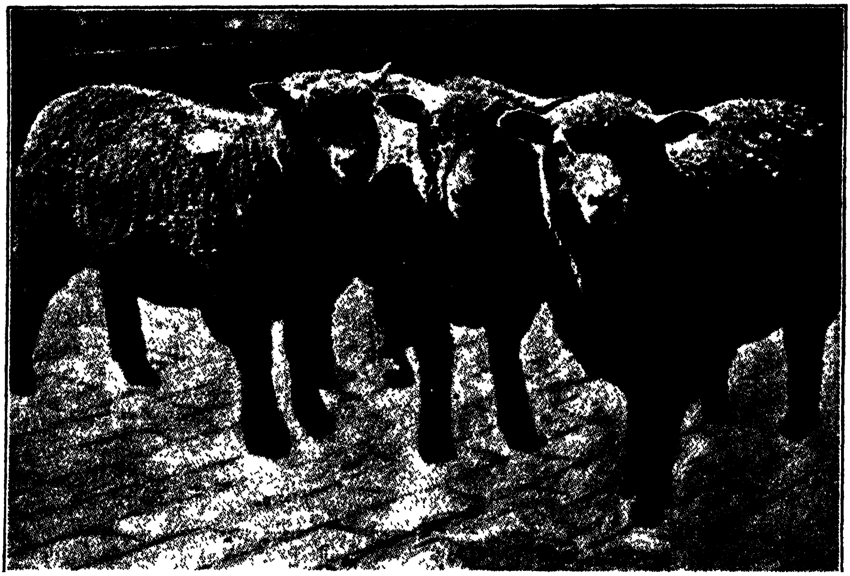
MANAGEMENT.

There are some large flocks of sheep in New Zealand and the average size is 961, but this figure is reached because of several large holdings and approximately half the sheep are held in flocks of under 500, and three quarters in flocks of under 1,000. Therefore, generally speaking the flocks are small, and careful and constant attention is possible.

In the mountainous and dryer areas of the South Island the winter is cold and snow is regularly experienced in many localities, with the result that there is usually a high mortality, particularly with the breeding ewes. As a consequence it is a regular practice to only mate sufficient ewes to keep the flock up to strength. The Merino is the breed kept in this country, and whilst wool of fine quality is grown, the fleece is light, about six to seven pounds, and the animals small. There is little doubt that the introduction of large-framed, strong constitutioned sheep from some of the South Australian studs would lead to improvement in the class of Merino now being carried.

In the hills country of both Islands Crossbred flocks are held and both wool and meat raised. Animals from these flocks form the basis of the fat lamb breeding flocks of the fattening farms. The ewes are mated to Romney Marsh or Corriedale rams, and whilst in some cases a high percentage of the progeny can be fattened on the farm and sent to the meat works, as a rule the greater proportion is sold as stores to graziers for topping up, whilst the ewe lambs are retained on the farm for breeding purposes. Such ewe lambs replace the older ewes sold to the fat lamb breeders on the lower levels.

The fat stock farms are situated in areas which either because of altitude or rainfall are not well suited to dairying, and except for stud flocks these invariably hold Crossbred ewes purchased from the hills. They are bought in early autumn, usually when full mouth, costing about £1 per head. At times only one lamb is taken from them before disposal, but as a rule they are kept for two seasons. Large annual ewe sales are held, at which lamb raisers secure their requirements, but when a breeder is obtaining full satisfaction from the line of ewes he is using, he invariably endeavours to make his future purchases from the same source.



[*From Agriculture in New Zealand (Mr. Spafford).*

Typical Export Lambs.

There are, therefore, three main classes of sheep farms, namely, the Merino farms, the hills farms, and the fattening farms, with a definite linking up between the two last-named, as the fattening farms obtain their ewe requirements from the hills, and top up the surplus and wether lambs on their better pastures and supplementary crops.

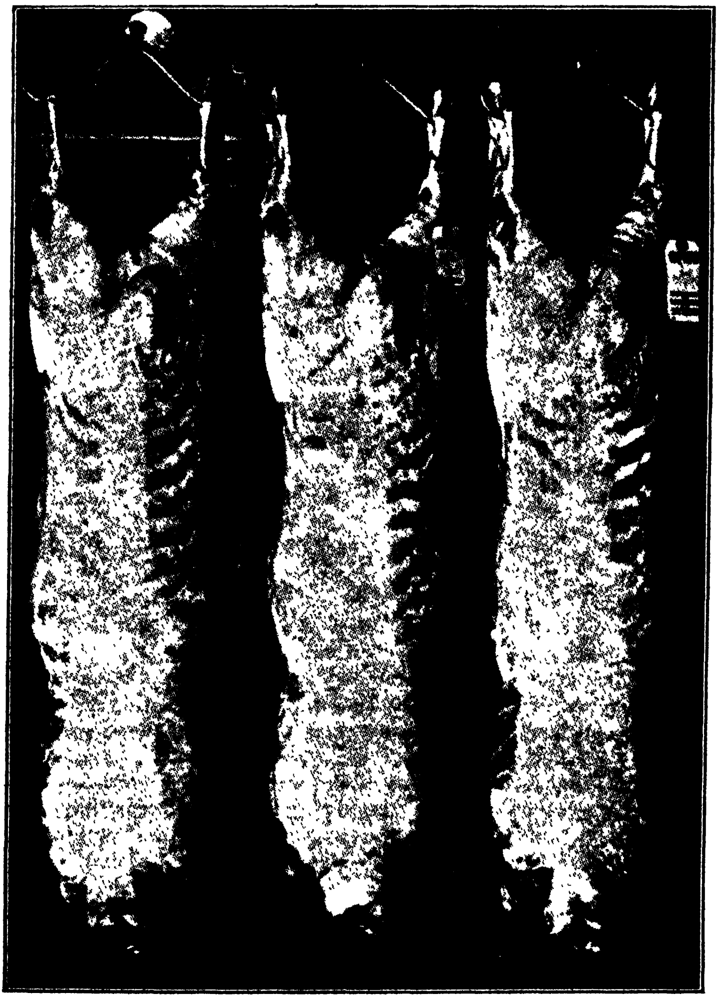
The result is that amongst the crossbred sheep few wethers are retained, and an analysis of the sexes over the whole of the sheep population shows that there are approximatey 65 per cent. ewes, 24 per cent lambs (mainly ewes), 9 per cent. wethers and 2 per cent. rams.

The average lambing is almost 90 per cent., but that for the fat lamb breeding flocks is invariably higher, with under 100 per cent. an exception, and up to 130 to 140 per cent. not uncommon. This high natural increase appears to be due to several reasons. The Crossbred ewes are naturally prolific, the change from the hills country to the better feed of the plains results in flushing and greater fertility; the rams used are young, vigorous, and at least two added to every hundred ewes, whilst close attention is given to the flock throughout lambing time.

Most lambs are dropped during September and October, and from the fattening farms practically all are sent to the freezers direct from their mothers. However, this is not the case with the surplus lambs from the hills, and about 20 per cent. of the lambs exported from New Zealand are weaned and topped up on other pastures prior to slaughter.

MARKETING.

Because of the large export trade the local prices are governed by export values. Consequently there is practically no breeding specially for the local trade as is the case in South Australia.



[*From Agriculture in New Zealand (Mr. Spafford).*

Carcasses of first quality Export Lambs.

Very great care is taken in the selection of the lamb for the freezers, and as a rule each animal is handled before being marked for disposal. Every breeder endeavours to forward only prime lambs dressing between 32lbs. and 36lbs., and if a lamb does not reach the standard set it is kept on the farm until ready. The animals are mainly transported by motor lorry and as far as possible every animal is dressed on the same day that it leaves the farm. Rapid transport and slaughter is possible because there are 35 freezing works conveniently situated to suit the producer. A seaport is not regarded as essential, and some are over 100 miles from a port. In such cases the carcasses are taken on to the ship in insulated cars. Twenty of the meat works are in the North Island and 15 in the South, whilst all except two have adopted the chain system of handling.

The average killing capacity per day is about 3,725 sheep and 130 cattle, whilst Petone in the North Island is the largest, being capable of handling 10,000 sheep and 100 cattle daily.

The farmer may market his export lambs under several systems, namely:—

Under schedule
By sale direct on farm, truck or works
Export on own account
At livestock markets

Sale under schedule is the usual method, when the farmer is paid a definite amount per pound according to the weight and quality grade of each carcass, whilst the works retain skins, offal, &c. Next in order of popularity is per head on the farm, trucks, or delivered at the works; whilst some may be exported on the farmer's account, but very few pass through the saleyards to be purchased by export houses.

The standard of inspection for export meat is high, and no carcasses are sent away showing any defects or disease. Every meat works must supply a daily return to the Department of Agriculture indicating the causes for rejection, so that the trouble can be investigated.

The grading is carried out on a standardised system set by the Meat Board, although each works has its own private brand.

The grades are:—

First Quality Lamb—

2s	Up to 36lbs.
8s	37 to 42lbs.
4s	43 to 50lbs.
Tegs	Over 50lbs.

Second Quality Lamb—All weights.

In addition some works divide the first grade lambs into Downs and First Quality, the Down being an almost perfect carcass.

There are no third grade carcasses and any failing to reach the second quality are consumed locally. As evidence of the care taken in marketing there is the fact that of the 9,000,000 lambs exported last year 85 per cent. were graded as Down or First Quality carcasses.

Because the great majority of these lambs are sired by Southdown rams from a uniform type of ewe, there is a great regularity in the conformation of the carcass obtained. It is this uniformity and evenness which is the striking feature of thousands of carcasses hanging in the cooling and freezing chambers of the New Zealand Meat Works and is a marked contrast to that which may be seen on almost any day at the Port Adelaide Depot.

An export market in mutton has been established and the cull ewes from the lamb breeding flocks are disposed of in this manner. When the lambs are weaned these ewes are topped up and sent to the freezers, the average price realised during the past season being about 14s. per head.

The grades into which these carcasses may be placed are:—

First Quality Mutton—

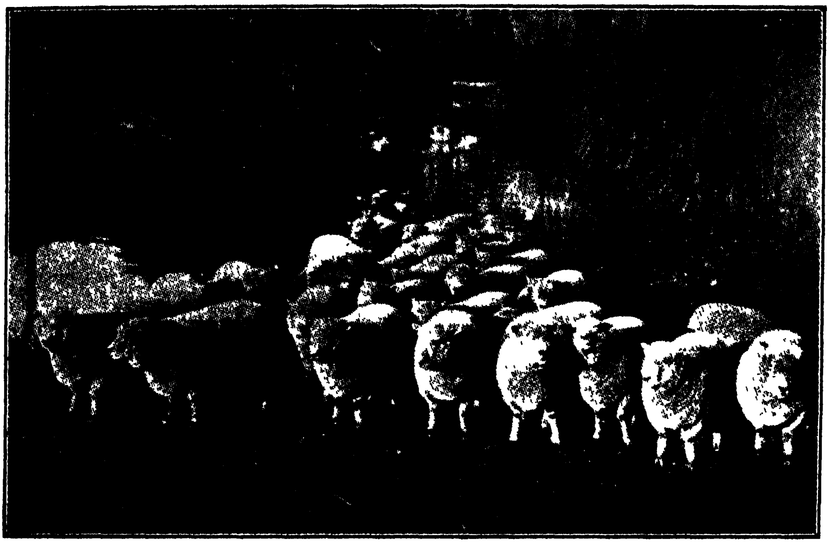
1s	Up to 48lbs.
7s	49 to 56lbs.
3s	57 to 64lbs.
9s	65 to 72lbs.
5s	73 to 80lbs.

Second Quality—All weights.

Practically the whole of the lamb and mutton is exported to England, with a very small proportion to the Pacific Islands.

Since its appointment the Meat Board has concentrated on advertising and propaganda work. All the first grade carcasses are attractively labelled, and everything possible is done to draw the attention of the consuming public.

The season is much later in New Zealand than is the case with Australia and South Australia in particular, and New Zealand meat chiefly reaches the United Kingdom from February to August, whilst almost 60 per cent. of that from Australia is sold during the months of November, December and January, a fact of distinct importance to us.



[*Photo., The New Zealand Farmer.*

Stud Southdown Ewes on a Canterbury Farm.

WOOL.

Wool is the most important single commodity exported from New Zealand, but it gains its value from the total quantity produced rather than the quality of the produce. The average fleece is only a little more than 8lbs. and is of the Crossbred type.

Breeders have concentrated more on carcass than on the wool, because of the relative value of meat and wool, and in order to secure heavier fleeces have tended to use stronger woolled Romney Marsh rams. At the same time hairiness developed, and complaints were received from overseas manufacturers on this account. Hairy fibres, unless very coarse, are not easy to detect, and it was realised that some simple test which stud breeders could utilise was necessary for the selection of animals and the improvement of the wool.

The problem was taken up by the Department of Agriculture and continued at Massey Agricultural College, with the result that what is known as the Benzol test has been evolved.

This test is based on the fact that pure wool is solid, whilst hair is hollow. Pure wool and benzol have nearly the same refractory index, and therefore if wool is immersed in benzol it is rendered practically invisible, whilst hair shows up as a white thread owing to the hollow space.

The apparatus is simple, being merely a shallow tray about 10in. x 8in. coated with black porcelain enamel, into which a piece of plate glass will lie with about half-inch space at the edges. The sample of wool is washed in petrol to remove the dirt and grease, and after teasing out to a thin layer about six inches wide, is placed in the testing tray. The benzol is added and the wool held down with the glass cover. The hair is then seen standing out white and clear against the black background, whilst the wool is invisible.

Whilst the percentage of hair can be estimated by comparison with photographic standards, a photo-electric test has been perfected at the College, which accurately measures the amount of hair present.

The College will test animals for breeders, and the opportunity is being freely availed of. The laboratory is working at full pressure, and some thousands of samples are being examined annually.

From rams 18 samples of the wool are cut, six from the hind quarter, six from the side and six from the shoulder. These are tested and the animal classified according to certain standards fixed upon. With ewes, hoggets and lambs only six samples are taken. Usually the whole flock is done, and as each animal must be marked, the subsequent report and classification assists in culling.

The charge for these tests is 3s. per head for rams and 1s. for other sheep, plus travelling expenses for the collection of samples.

Definite results are being obtained following the mating of tested animals, and there is little doubt that the Benzol test will quickly lead to improvement in the wool quality of the Romney Marsh breed, and consequently the quality of the fleece from the Crossbred sheep.

The work so far has been confined to Romneys, but there is no reason why it cannot be applied to other breeds, and may even be of value to Merino studs in this State.

DISEASES.

A number of sheep diseases occur but are rarely permitted to become serious, because of the careful and efficient precautionary measures taken. For example:—The fattening country is not particularly healthy, but by the purchase of full-mouthed ewes, and their disposal for export as frozen mutton after one, or at the most two seasons, followed by replacement with healthy animals from the hilly country, serious losses are avoided.

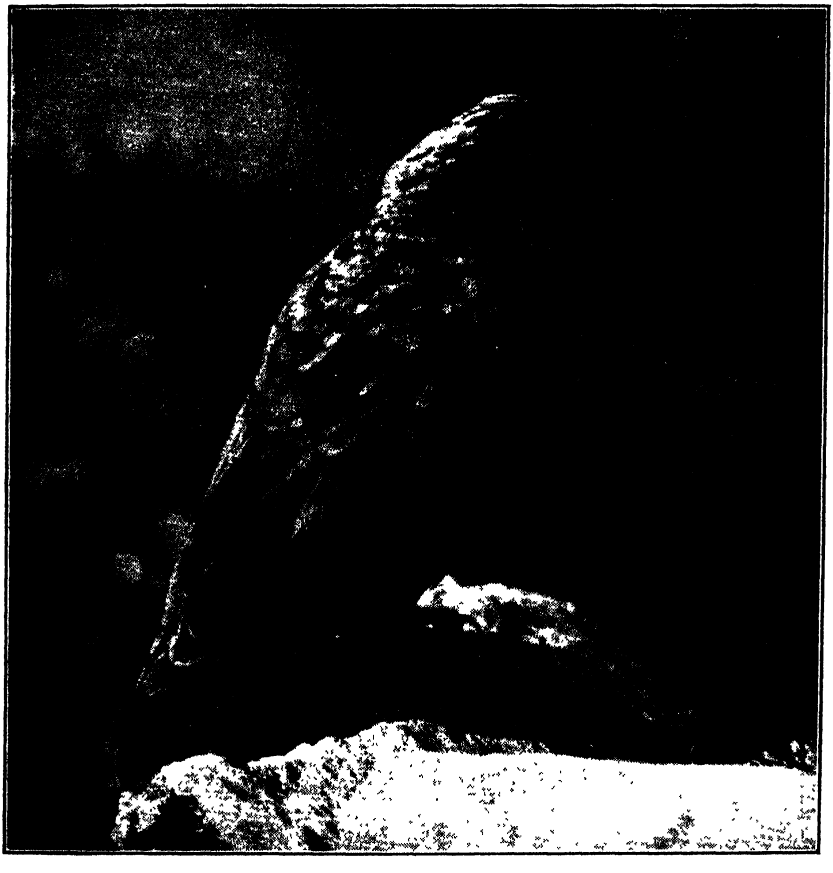
Again, in the case of footrot, stockowners do not wait for the disease to become prevalent throughout their flock, but pare the hooves and pass the animals through foot-baths in late summer. In this way the danger of infection from diseased sheep which carry the germ throughout the year and thus reinfect the grazing fields, is reduced.

It is the early treatment and precautionary measures with stock troubles generally, which is the outstanding feature in keeping disease in check in New Zealand and is an example which could be followed with advantage in South Australia.

Whilst the Romney Marsh sheep is resistant to footrot it is not immune, and this disease is one of the most troublesome in New Zealand. Treatment commences in late summer, at which time, although a few animals may be lame, the flock is not seriously affected. The feet are trimmed, wounds dressed, and the animals run through a foot-bath. In some cases a proprietary arsenical mixture is used, whilst in others a concentrated solution of copper sulphate or formalin is preferred. The treatment does not materially differ from that with which we are familiar, but the important point is that action is taken early in the season, and if necessary regularly continued.

Stomach worms constitute one of the most important troubles and drenching with a solution of bluestone and black leaf forty is the regular treatment. Pulpy kidney is a wide-spread disease amongst lambs born on the fattening country, particularly when the pasture is not properly controlled. The trouble appears to be associated with over nutrition and lack of exercise, and the usual treatment is to yard the flock for about 24 hours every five to six days until the mortality ceases.

Fatty gland, or caseous lymph-adenitis, which is a serious cause of rejection of export carcasses in South Australia, is not prevalent in New Zealand. On farms where it has been located, the infection has not been severe, and by the culling of affected animals and the disinfection of shearing machinery, &c., the spread has been checked, whilst officers of the Veterinary Department are of the opinion that with care the disease will be eliminated.



[*Photo., New Zealand Tourist Bureau.*

The Kea Parrot, an inhabitant of the mountainous country of the South Island. It attacks sheep, eating into the kidneys, and almost invariably causes injuries which prove fatal. Fortunately, the birds are rather rare nowadays.

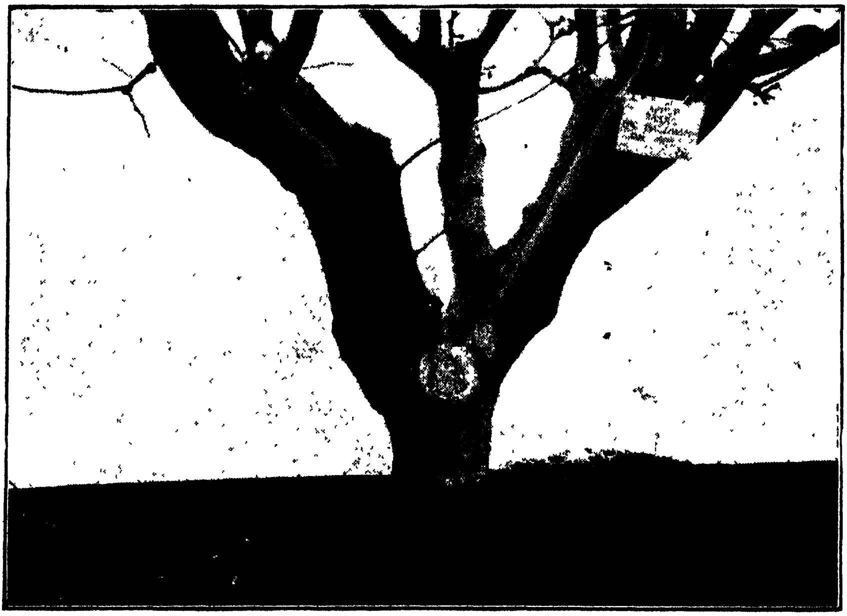
There are several areas where mineral deficiency occurs, chief of which is the pumice land of the North Island, and in this country iron licks are being used with success.

(*To be continued: the next portion of this report will deal with Pigs in New Zealand, wheat and other crops, and will conclude with Impressions and Summary.*)

REWORKING FRUIT TREES.

[By R. Fowler, Manager Blackwood Experimental Orchard.]

In many of the old established orchards in South Australia, numerous varieties of apples and pears are to be found which a decade ago were regularly shipped to overseas markets and realised at that time remunerative prices. With the extension of planting in South Australia and other States, however, and the entry of other countries into the apple and pear export trade, very keen competition has developed, which has shown that many of the old varieties cannot reasonably be regarded as having any commercial future. As the list of varieties now favoured for export has been reduced to about 40, with the possibility of this number being still further reduced, growers are now confronted with a very important problem—the elimination of the unsuitable or unprofitable varieties from the orchard. It may be possible to retain a few of these, for which a profitable outlet can be found on local or interstate markets, but in the majority of cases, it will be found preferable to convert the trees to more popular varieties that can be used for either local or overseas trade.



[*Photo.*, *E. W. Pritchard.*

Fig. 1.—Limb removed owing to attack of *Polystictus versicolour*. Wound healing without further spread of infection.

Where a large number of trees is involved, the problem is a very serious one and resolves itself into the choice of either conversion to the desired varieties or grubbing out and replanting; the latter course will not commend itself to many growers. The loss of time, the cost of bringing other trees to the productive stage and the difficulty of establishing new trees in a bearing orchard preclude any possibility of this course being adopted extensively, so that the grower is practically forced to adopt some method of grafting or refurnishing.

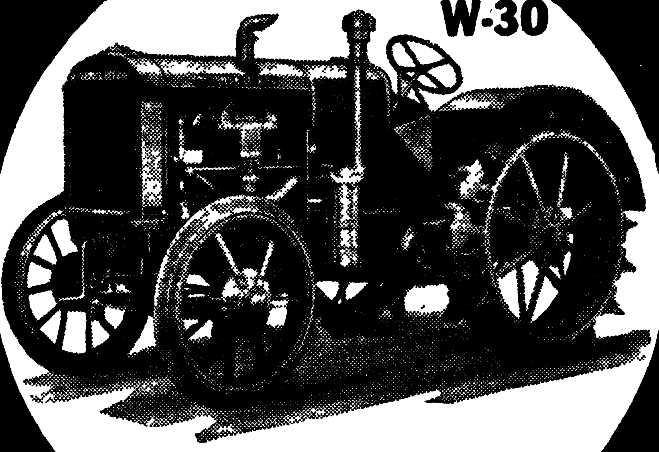
OUTSTANDING TRACTOR VALUE

McCORMICK-DEERING W-30



For 75% of all farm work. Will do the work of eight horses. Controls made for finger-tip performance. Delivers power at drawbar, belt-pulley, power take-off.

Every tractor in the McCormick-Deering line is quality-built on intimate knowledge of power farming from its inception. For row-crop, vineyard and orchard work the handy, nimble, compact little tractors of the "12" series, operating on kerosene, solve the labour problem with unvarying mechanical service.

For farms of any size, anywhere, the larger tractors of the comprehensive McCormick-Deering line including wheeled and crawler tractor types, operate with the same economy and efficiency from ploughing and seeding time to harvest. The tractor you need is in the McCormick-Deering line. Write for catalogue.

McCORMICK-DEERING

T-20 TracTracTor

For soft soil and hillside work and wherever tenacious ground grip and steady, unfaltering tractive power are required, McCormick-Deering T-20 TracTracTor is invaluable. It operates on kerosene and is built for long years of the most gruelling working conditions. . . . Also available, the TD-40 Diesel TracTracTor.

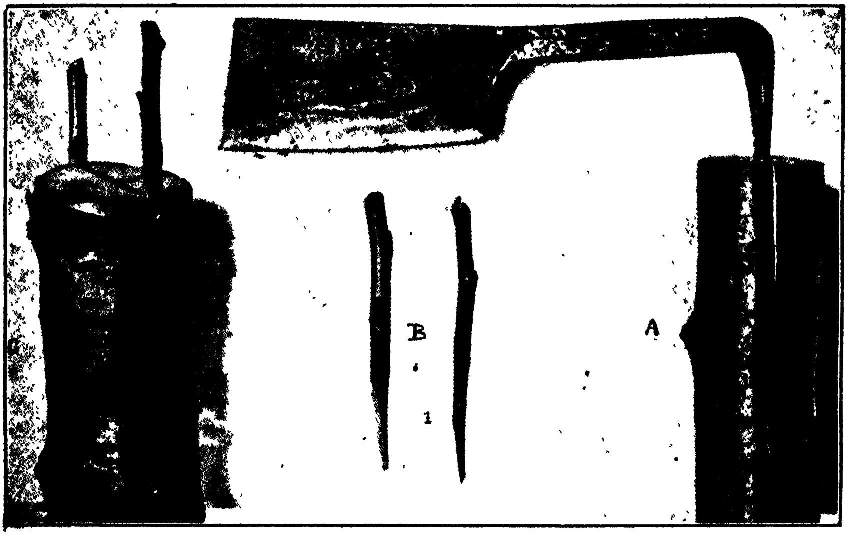
In the past, various methods of reworking by inserting grafts on the main limbs severed just above where they branch out from the main trunk were favoured, but the prevalence during recent years of *Polystictus versicolour,* a wound fungus which has caused considerable loss and injury to trees cut hard back in this way, has made it necessary to seek other methods of conversion or reworking.

Polystictus versicolour is a disease which has not yet been controlled with any measure of success. It generally attacks trees at large open wounds, particularly if these are situated on the main limbs, such wounds apparently offering ideal entry for the fungus. No effective way of treating the established fungus is known, and the only safe procedure is to cut out the infected area or amputate the limb showing signs of infection. This must be done at once, as infection travels fairly quickly down the limb, and once it has entered below the crotch, the chances of saving the tree are small.



[*From Brit. Min. of Agric., Bltn. No.* 2.

Fig. 2.—Top Grafting.—Cleft Grafting.—A, the branch of the stock is split transversely with a chisel of chopper. B, the grafts, with long, oblique surfaces cut on each side of the stock bud, B1. These are inserted in the cleft in the stock C, bound with raffia, and then waxed or "pugged."

One large limb of the tree shown in Figure I. developed *Polystictus* after being worked over in 1928. The limb, a very large one, was immediately removed, the wound disinfected and painted, and no further spread of the infection has been noted

The risks of infection appear to be considerably reduced if the reworking is done higher up along the main limbs, small wounds callousing over more readily than large ones.

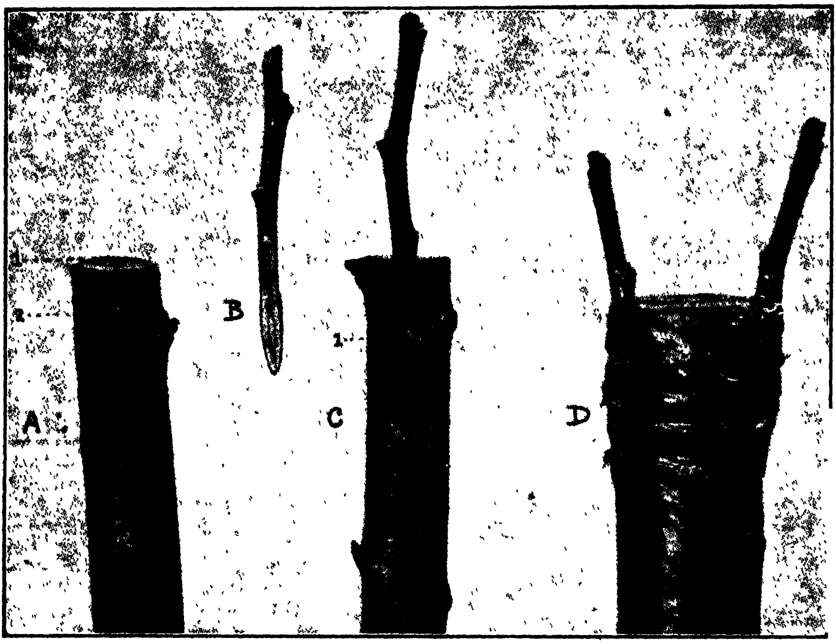
Under the old method of reworking, large trees in full bearing often took 3 to 4 years before there was any crop return, but under modern methods this serious loss of time is obviated and the production period is not shortened to any great extent.

From experience gained during the past few years and a careful study of all the factors involved, it is now possible to recommend methods of converting unprofitable fruit trees to more profitable varieties, which are applicable to most types of deciduous fruit trees, and which will eliminate some of the difficulties already enumerated.

So that a fair comparison of the various methods of changing varieties can be made, the first portion of this article will review methods which have been in general use for some time. More modern developments will be dealt with in subsequent sections.

GRAFTING.

Grafting may be described as the causing of a scion, comprising one or more buds cut from one plant, to become part of another, called the stock. There are many ways in which grafting may be effected, but the same principle applies to each one. To effect a union between stock and scion, the cambium layers which are situated just beneath the bark must be brought in close contact, and air and other foreign substances excluded.



[*From Bltn. No.* 2, *Brit. Min. of Agric.*

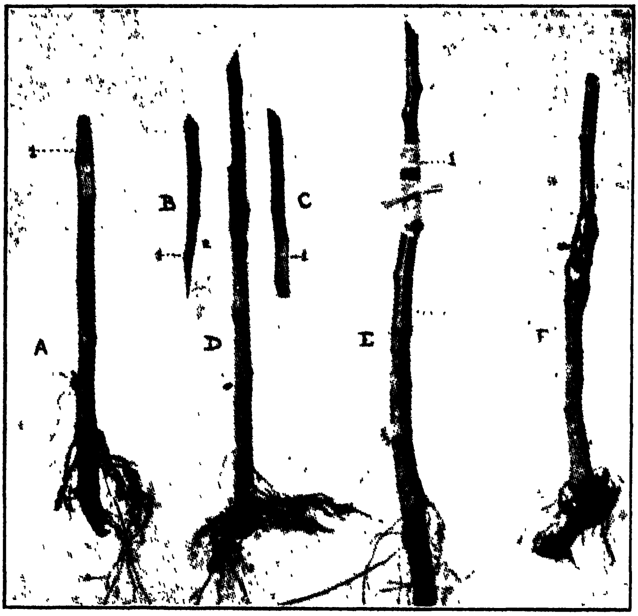
Fig. 3.—Top Grafting—Rind or Bark Grafting.—A, a branch of the stock prepared to receive the graft; A1, the pared surface at the top of the branch; A2, the longitudinal cut in the rind. B, the graft. C, the graft slipped beneath the rind of the stock; C1, the stock bud. D, the operation completed. The grafts have been bound to the stock with raffia, and all the cut surfaces have been waxed.

It is not necessary that the cambium layers should meet perfectly in all parts of the cut surfaces of stock and scion, but the more perfectly they are brought in contact, the greater the chances of fusion between stock and scion. The success of the operation of grafting depends largely upon the smoothness of the cut surfaces of the parts brought in contact and the accuracy of the joining.

Scions should be cut from well-ripened, mature wood of the previous season's growth. They should be cut in winter and well before the buds swell in spring, and should be kept partly buried in moist sand or covered with damp bags or litter in a cool, shady place, as it is necessary that they should remain in a more or less dormant state until required. It is generally conceded that grafting is usually more successful when the stock is in a more advanced stage of vegetative activity than the scion, and the operation is therefore best done in early spring when the sap is moving freely in the stock.

The different styles of grafting may be classified in respect to the place where the scion is attached to the stock, as Root Grafting, or the insertion of the scion in the root of the stock, used in nursery work; Crown Grafting, or the insertion of the scions in the stock at the surface of the ground; Stem Grafting, or the insertion of the scion in any part of the main stem or trunk, and Top Grafting, or the insertion of the scions in the top or branches.

Grafting may also be classified in respect to the way in which the union between the scion and the stock is made as Cleft Grafting, Bark Grafting, Whip Grafting, and Strap Grafting, &c. The variety of methods is due mainly to the differences in the sizes and ages of the stocks, and no practical purpose would be served by describing all the modes of grafting that are practised, as in many cases there are but slight differences, often more fanciful than serviceable. The four methods just mentioned are those generally used and they are ample for most requirements.



[*From Bltn. No. 2, Brit. Min. of Agric.*

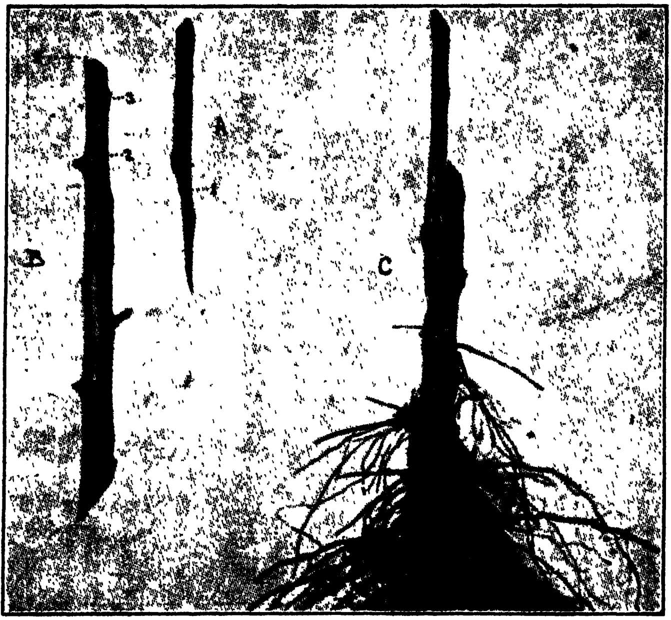
Fig. 4.—Whip Grafting—Graft and Stock the same size. A, the stock, cut to receive the graft; A1, the position of the tongue. B and C, grafts ready for applying to stocks; B1, the stock bud; B2, the long, oblique cut surface; C1, the position of the tongue. D, graft and stock fitted together. E, graft and stock bound together with rafia; E1, the stock-bud which is left uncovered. F, the operation completed, all the cut surfaces covered with grafting wax.

CLEFT GRAFTING.

This method is commonly practised for large stocks or trees that have been headed back and whose branches are too thick for Tongue or Splice Grafting. A cut is made with a saw at a right angle through the limb and about a foot or so from where the limb branches out from the main stem, care being taken not to loosen or tear the bark from any part of the stub. The exposed end is then smoothed over with a sharp knife to facilitate healing, and then split with a broad, thin chisel or with a grafting tool such as shown in Figure 2. The Cleft is held apart as in Figure 2A, or a wedge is inserted to allow the scions to be pushed carefully into position, taking care that the inner bark of the scion fits that of the stock. The wedge is then withdrawn and the scions tied in position with raffia. The scion should contain 2 to 3 buds and is prepared by sloping the lower portion in the form of a wedge about 1½in. long, one edge of the wedge being thicker than the other and set in the stock with the thicker edge of the wedge to the outside. This will hold the scion firmly in place and the greatest pressure will come at the outer edges where growth takes place.

In order to be sure that the growing tissues come in contact, the scion is sometimes set at a slight angle so that the growing wood of the scion must cross that of the stock at some point.

As a rule two scions are set in each limb, one at each edge of the Cleft as shown in Figure 2c.



[*From Bltn. No. 2, Brit. Min. of Agric.*

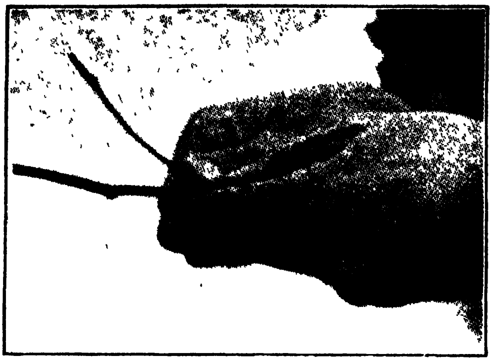
Fig. 5.—Whip Grafting.—Stock larger than graft. A, the graft ready prepared; A1, the position of the tongue. B, the stock cut to receive the graft; B1, the square cut; B2, the longue oblique cut; B3, the tongue. C, graft applied to the stock, the tongues fitted together.

If both scions grow, the less desirable one may be removed. To complete the operation, all cut surfaces are covered with grafting wax from the lowest point of the Cleft section upwards. At one time a mixture of clay, straw and cow manure was used to seal up the grafts, but other mastics are now available which are less liable to crack or be washed off, and less bulky to carry about and more easily manipulated.

Cleft Grafting is not to be recommended, because the split in the branch of the stock, besides weakening it, serves as a harbour for insects, and makes it improbable that the wound will ever properly heal over.

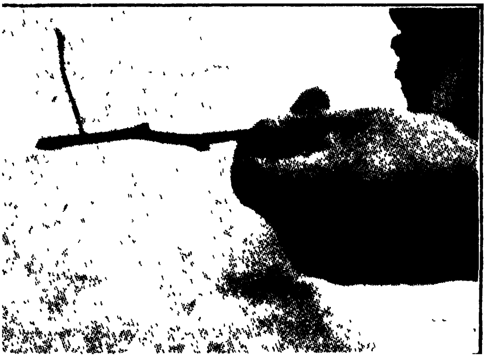
BARK GRAFTING.

This method of grafting does not injure the stock to the same extent as Cleft Grafting, a better union is generally made, more scions can be placed around a large stock, the operation is more quickly performed and with more chance of success. Until recent years it was the common method employed for reworking fruit trees by most Australian fruitgrowers. It is known in England and France as Crown Grafting.



[*From Bltn.* 63, *Vic. Dept. of Agriculture.*

Fig. 6.—Cutting the "strap" in scion ready for strap graft. Note the bud near the end of the strap (the portion raised). It is wise to have a bud so placed.



[*From Bltn.* 63, *Vic. Dept. of Agriculture.*

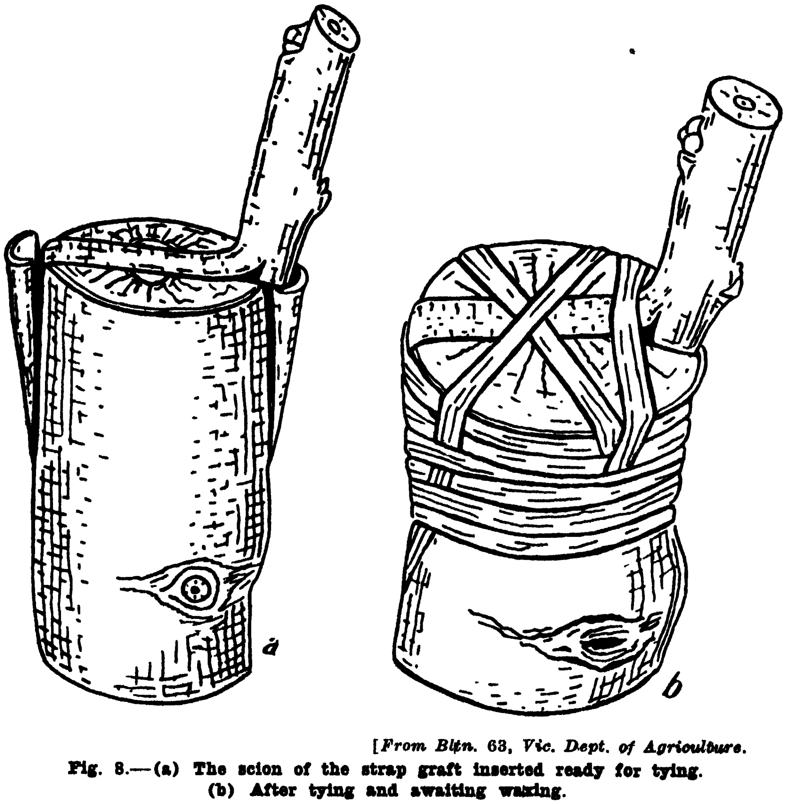
Fig. 7.—The scion for a strap graft prepared ready for grafting.

Several different methods may be employed but the principle is much the same in each case, the scion being placed between the bark and the wood tissue of the limb. It can best be done when the bark of the stock lifts readily from the wood, that is, when the sap is in active movement.

The initial treatment of the tree is the same as in Cleft Grafting, but instead of splitting the branch, a vertical incision 1 to 1½in. in length is made in the bark. The bark is then gently eased away on either side at the top of this cut.

A scion containing 2 or 3 buds is prepared by making a long, slanting, plain surface cut at the lower end and slightly longer than the incision on the branch. A wedge point is made by cutting away a small portion of the lower extremity on the bark side so that the bark at the base of the scion will not be bruised or crumpled back when the scion is gently pushed into position between the bark and wood tissue of the severed limb. The wedge point will facilitate the operation and help to ensure the success of the graft. The scion should be pressed downwards until the upper edge of the cut surface is almost level with but not below the top of the branch (Figure 3c).

A stock bud is sometimes left on the reduced portion of the scion as shown in Figure 3c. This bud generally remains dormant but should the top of the scion be broken away by accident, it will burst into growth, thus repairing the damage.



[*From Bltn. 63, Vic. Dept. of Agriculture.*

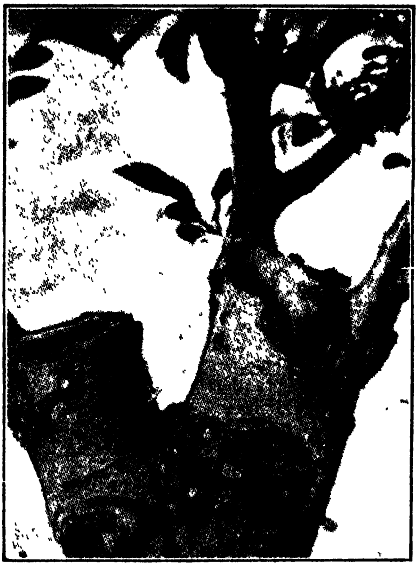
Fig. 8.—(a) The scion of the strap graft inserted ready for tying.
(b) After tying and awaiting waxing.

The graft is then tightly bound in with raffia, care being taken to see that the top tie is as tight as possible. This is rather important, for a perfect union at this point is necessary to prevent the graft being blown out by the wind or broken out when carrying a crop of fruit. It is now common practice to secure the scions to the stock with ½in. to ⅝in. x 20 G. brads. If one scion only is being used it is better placed on the top side of the stub, the cut is then more protected from the weather and the graft is less liable to break away.

A variation in Bark Grafting when smaller limbs are being treated and only one scion inserted, is to make the cuts in the branches obliquely instead of at right-angles, by which means they are better protected from the weather. A small tongue may be left on the inner side of the scion which is placed at the top and made to fit accurately on the sloping face of the stock, thus bringing a larger space in contact, with a better chance of strong union.

WHIP OR TONGUE GRAFTING.

This method is almost invariably used for Root Grafting and nursery work when stock and scion are approximately of the same diameter. In making a Whip Graft, one long, smooth, slanting cut is made at the top of the stock with a sharp knife. The knife is then placed on the cut surface near the top and the stock is split in the direction of its longest axis, forming a tongue. The same form of split is made in the cut face of the scion to form a tongue or wedge to fit into the opening made in the stock, thus locking stock and scion together. Some difference in diameter of stock and scion may be disregarded, but it is necessary in order to effect a union, that the edge of the stock and scion must be even on one side. As with other forms of grafting, stock and scion, if worked above ground, must be tightly bound with raffia and the cut surfaces waxed over to keep them air tight. Root Grafts are bound but not waxed. Figures 4 and 5 illustrate working methods.



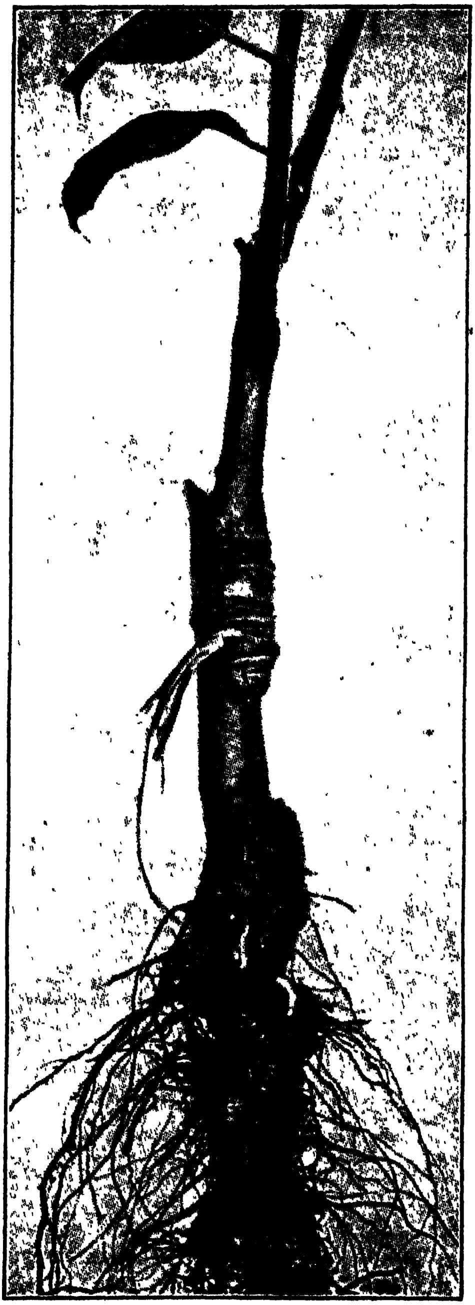
[*From Bltn. 63, Vic. Dept. of Agriculture.*

Fig. 9.—A Close-Up View of Grafts—Two-year-old Scions. The "strap" will quickly cover the whole of the cut surface.

STRAP GRAFTING.

This is really an improved type of Bark Grafting so named from the strap of bark used in fixing in the scion. The chief advantage is that a much speedier callus is formed than with other methods of grafting, thus preventing decay of the stock, and giving greater stability to the limb. A little more time is occupied in the operation, but with practice, the operator can quickly become expert. It is best adapted for limbs up to 1½in. in diameter, but may be used on larger stubs.

The stock is prepared in the same manner as for Bark Grafting but the scion, however, is treated differently. It is so cut that a long strip of bark with a thin piece of wood attached remains on the back of the scion, extending from the upper point of the sloping cut usually made in the preparation of a bark graft. After



[*From Bltn. No. 2, Brit. Min. of Agric.*

Fig. 10.—A Graft seared by raffia.

the scion has been pressed into position this strap of bark is stretched across the cut surface of the limb, the end is turned down an inch or so and inserted between the wood and the bark, on the opposite side to the scion and in the same manner. The strap should be securely fastened down, as it must rest firmly on the cut, otherwise it is likely to curl up and will not take. The whole is then securely tied and all exposed cut surfaces waxed over to exclude air. Figures 6 and 7 illustrate the preparation of the scion for Strap Grafting, and Figure 8A the method of inserting scion, and Figure B tying up.

Fig. 11.—Pear tree, crown grafted, mounded over with soil.

In the illustration, two vertical incisions have been made in the bark, the distance between the cuts corresponding with the width of the scion. This method is sometimes used instead of the single cut previously described. Figure 9 shows Strap Grafts 2 years old.

GRAFTING WAX.

The object of using a mastic or Grafting Wax is to exclude air and all foreign substances from the points of union, and to prevent the drying up of the sap at this point. There are several recipes for making Grafting Wax, the ingredients generally being beeswax, resin and tallow in varying proportions. A good wax is made by mixing the following ingredients:—4lbs. resin, 2lbs. beeswax and 1lb. tallow or linseed oil. If it is desired to have the wax of a greater hardness than will result from this formula, the resin may be increased to 5lbs. and the beeswax to 2½lbs. The resin and beeswax are melted with the tallow or in the linseed oil, and when thoroughly hot, the mixture should be poured into cold water and when cool enough to handle should be pulled and worked until it is light coloured and grained.

In applying the wax the heat of the hand is sufficient to soften it; it may also be melted and applied hot with a brush, if care is taken not to make it sufficiently hot to cause injury to the bark.

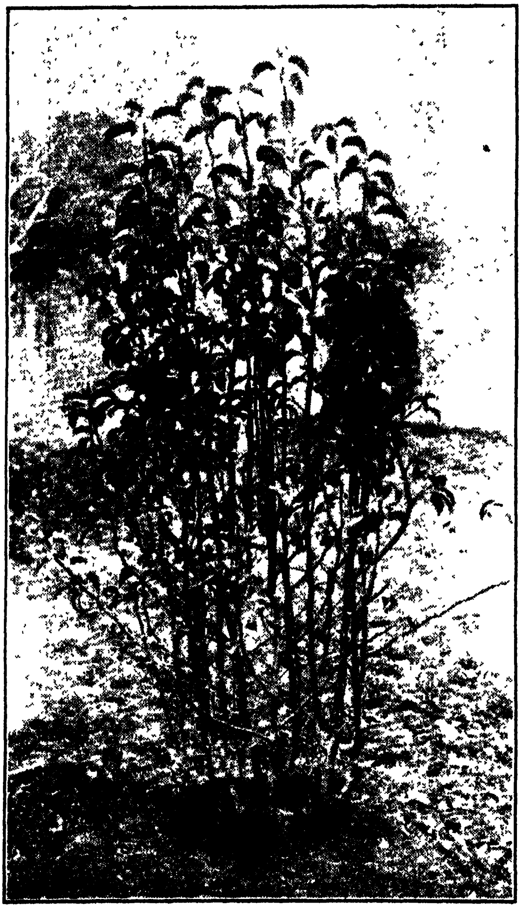


Fig. 12.—Large Glou Morceau pear in late G. R. Laffer's Orchard, worked over to Parkham's Triumph. Stock, 16in. diameter, on which 14 bark grafts have been inserted. Growth, 1-year-old.

If wax bands are prefered these can be made by dipping wide strips of calico into the boiling mixture and when thoroughly soaked, drawing them through two pieces of wood to remove surplus wax which collects in irregular lumps on the calico. When cold, the calico can be torn into strips of any desired width, and these strips, for convenience in handling, can be wound round a stick in the form of a ball. The sticky nature of wax made from this recipe is its great disadvantage.

it is very difficult to keep the hands and grafting implements clean and the work of the operator is more or less impeded. In modern mastics this difficulty has been overcome and combinations of paraffin wax and crude petroleum jelly have taken the place of grafting wax.

There are also prepartions on the market which after a time rot away the raffia bands, thus saving time in the removal of the bands and preventing the searing of bark through neglecting to do so as in Figure 10. Wax or waxed bands should be used only on cut surfaces and while sufficient should be applied to exclude the air thoroughly, it is not wise to use overmuch. The heat of the sun may cause it to run, with probable damage to adjoining bark.

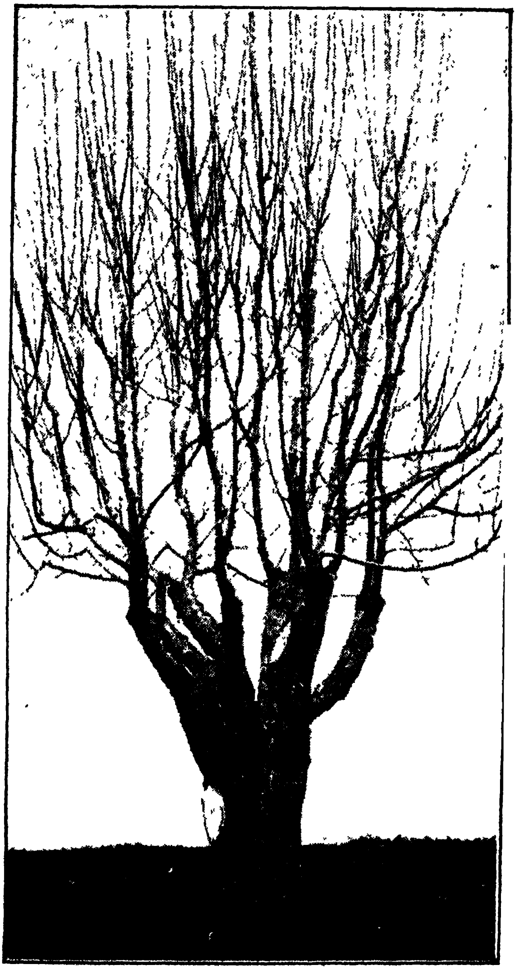

Fig. 13.—Pear tree, bark grafted on main limbs, 3 years old, producing small quantity of fruit this season.

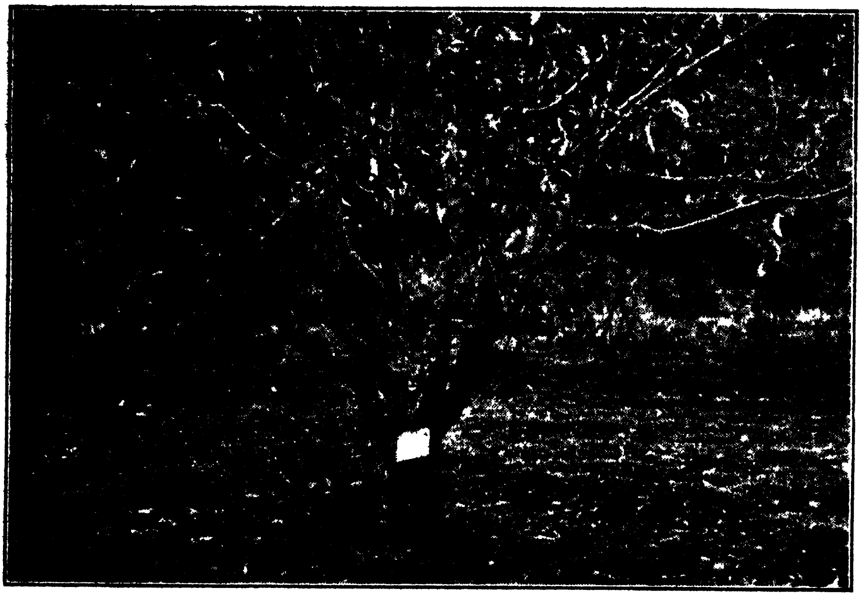

Fig. 14.—Shockley, reworked to Granny Smith in 1926, with bark grafts, showing typical growth.

Fig. 15.—View of Pear Tree in late G. R. Laffer's Orchard, crown grafted with bark grafts, showing fusion of scions and the healing over of stock. Hundreds of pear trees in this orchard are worked over in this way.

WHAT A PERFECT COMBINATION

FOR SPLIT-SECOND STARTING

VOLATILITY in petrol; FLUIDITY in motor oil—these are the two essentials for easy starting this winter. YOU GET BOTH by using Super Plume Ethyl and Winter Grade Mobiloil. This perfect combination for Winter motoring guarantees you Split-second Starting during the coldest days and nights. Avoid engine wear—save power—save petrol. During Winter—use this perfect combination.

Gear Oil: For Winter-ease gear shifting use the new Mobiloil "C"

PREPARATION OF THE TREE.

The tree to be grafted can be cut down any time during the dormant period or even at the time the operation is to be performed. It is, however, better to remove the head during pruning operations, leaving longer arms than are necessary. These can then be shortened back to the desired length at the time of grafting.

Crown Grafting, cutting back to the main trunk just above ground level (Fig. 12) was once recommended, and though pears may succeed very well when grafted in this manner, it has proved unsuitable for apples. Fig. 12 is a view of a large pear tree, 16in. in diameter, in which 14 bark grafts have been inserted. Figs. 11 and 15 also show pear trees worked over in the same way, in different stages of development.

AFTER TREATMENT OF GRAFTS.

Care and attention is necessary after grafting has been done or much good work may be spoilt and time lost. Ties should be carefully examined at intervals of a fortnight or so, and removed before starting to cut into the bark. A fresh coating of wax should be applied to cut surfaces for several years. If more grafts have taken than are required, one or more can be removed. All shoots developing below the union should be removed as soon as noticed. When the grafts begin to grow vigorously, they should be supported by stakes driven in round the stock, to which the grafts can be securely tied. If not supported in this way they should be severely summer pruned to minimise the risk of having them blown out by the wind.

(*To be continued.*)

CHIEF AGRICULTURAL INSTRUCTOR.

APPOINTMENT OF MR. R. C. SCOTT, R.D.A.

Upon the promotion of Mr. W. J. Spafford to the office of Director of Agriculture, Mr. R. C. Scott, R.D.A., who has occupied the position of Supervisor of Experimental Work since 1927, has been appointed Chief Agricultural Instructor.

Mr. Scott is a graduate of Roseworthy Agricultural College, having gained the College Diploma (with honours), and with credit in Agriculture, in 1913. After a year's farming experience in the Booborowie district he was appointed Farm Assistant at the College and in July, 1914, he succeeded Mr. Spafford as Assistant Experimentalist. Subsequently, he held various appointments at the college besides that involving experimental work—Demonstrator in Agriculture, Assistant Lecturer in Agriculture, and he was constantly in collaboration with the Principal in the preparation and publication of the reports of that Institution. Besides the control of the important experimental work with fertilisers, rotation of crops and systems of tillage, Mr. Scott was successful in the selection and breeding of wheats. He was associated with selecting and fixing the type of the varieties Sultan and Felix. Besides others he raised Sword and Dan, both of which have become very prominent in recent years.

During the absence of the Principal from May, 1927 until July, 1927, Mr. Scott had charge of the College farm, and agricultural instruction to students.

In 1927 he was transferred to the Department of Agriculture in Adelaide to take a new position—Supervisor of Experimental work. In this office he has had control of the agricultural experiments carried out by the Department, including those conducted in co-operation with private farmers. He also had charge of the work at the Minnipa, Veitch and Booborowie Experimental Farms until they were closed, and during the past four years he supervised the operations of the Turretfield Seed Wheat Farm.

The experimental work of the Department covers all branches of agriculture, including cereals, pasture, fertilisers, tobacco, livestock, noxious weeds, insect pests, etc. The centres where they are conducted approximate 200 in number and are scattered generally from one end of the State to the other. In controlling this work, Mr. Scott has become thoroughly acquainted with the agriculture of South Australia and has a clear understanding of the varying conditions of soil, climate, rainfall, &c. under which agriculturists are working. He was further closely connected with measures taken to deal with the grasshopper infestation of 1934 and 1935, together with the organised effort which was successful in controlling the pest on the irrigated area of the River Murray.

When the Deputy Director of Agriculture was absent from the State for a period of six months on a tour of the Southern Hemisphere, Mr. Scott was called upon to undertake duties similar to those of the office to which he has just been appointed and attended all conferences of the Agricultural Bureau.

MR. R. C. SCOTT, R.D.A.

Early this year he was chosen by the Government to accompany the party of South Australian farmers which toured New Zealand, and thus had the opportunity of studying the agriculture of that country and gaining information of value to the State.

Besides reports dealing with the results of experimental work, Mr. Scott has written several articles for the pages of this Journal, which have been published in bulletin form. Principal among these are "Wheat Varieties," "Production of Fat Lambs," "Fat Lamb Production Investigation" (written in conjunction with Mr. W. J. Colebatch), "Pasture Improvement" (in conjunction with Mr. E. M. Hutton), and "Tobacco Culture" (in conjunction with Mr. S. P. Opie). His report on the visit to New Zealand is now being published and is being read with interest especially by those associated with the sheep and dairying industries.

Mr. Scott is an accomplished platform speaker and with his informative knowledge of a wide range of agricultural subjects he will always be a welcome visitor at Bureau conferences and Branch meetings.

IMPORTANT WEEDS OF SOUTH AUSTRALIA.

[By G. H. Clarke, B.Sc., Botanist, Waite Agricultural Research Institute,
University of Adelaide.]

Nos. 19 and 20.—BROAD-LEAVED AND NARROW-LEAVED COTTON BUSHES.

Asclepias rotundifolia, Mill. *Asclepias fruticosa,* L.

The plants described in the following paragraphs are introduced weeds, and though termed "Cotton-bushes," have no connection or resemblance with the native plants known by that name. The true Australian Cotton-bush is a dry country species of *Kochia,* which, like many of its allies the Salt-bushes, is esteemed as a native fodder plant of considerable value in parts of the arid interior. It derives its name from the occasional presence, especially during periods of protracted drought, of cottony galls which are supposed to be caused by some species of insect.

The names "Cotton bush" and "Wild Cotton" are also applied, however, to species of the African and American genus *Asclepias,* the *follicles* or pod-like fruits of which, like the *bolls* or capsules of the true Cotton Plant, contain very numerous seeds giving attachment to cotton-like hairs. Such hairs, in the case of certain cultivated species of the Malvaceous genus *Gossypium,* constitute the cotton of commerce; those of *Asclepias,* however, are of no commercial value: indeed, they are of silky rather than of cottony consistency, and, on this account, species of *Asclepias,* in America, are sometimes spoken of as "Silk-weeds." The more general name in that country is, however, "Milk-weed," on account of the copious milky sap which exudes from the plants when the surface is injured.

Of the two species to be described one has an almost world-wide reputation as a weed. Native originally to South Africa it is now established on the shores of most tropical countries of the world. This species, *Asclepias fruticosa,* L., occurs throughout temperate Australia where it is perhaps better known by its synonym, *Gomphocarpus fruticosus* (L.) R.Br. It is one of the few introduced weeds that appears to be able to compete successfully, in places, with the native sclerophyll vegetation which clothes so much of the eastern coastline of Australia; and, in the mistaken belief that it is a native species, the plant has sometimes been referred to, erroneously, as the "Native Cotton."

This species, now known in South Australia as the "Narrow-leaved Cotton-bush," has been the subject of much confusion in the past. It is not of very common occurrence in this State; indeed, so far from being regarded as a weed it is not infrequently cultivated as a garden plant; whereas it is recognised as a weed in parts of New South Wales and Victoria. On the other hand the "Broad-leaved Cotton-bush," *Asclepias rotundifolia,* Mill., which is relatively less common in the eastern States, does grow very vigorously under South Australian conditions, and is extremely common as a weed in the hills and foothills near Adelaide. This broad-leaved plant appears to have been mistaken, at first, for the narrow-leaved species. *Gomphocarpus fruticosus* was listed early as a noxious weed, though the plant aimed at was, evidently, *Asclepias rotundifolia,* or, as it was then called, *Gomphocarpus aborescens* (L.) R.Br. This gave rise to a state of affairs similar to that which had previously existed with respect to the Star and Saffron Thistles, and, as in the case of these thistles, the inevitable result has been to place both species upon the later list of weeds proclaimed noxious for South Australia.

Differences Between the Two Cotton-Bushes.

As their names imply, the two species differ markedly from each other in leaf form. In *Asclepias rotundifolia* the leaves are broad and oblong, one or two inches long, and of tough leathery consistency; whereas, in *Asclepias fruticosa,* they are narrow-lanceolate, from one to three inches long, and of thinner texture, as well as being of a paler, more yellowish, green colour. In both species they are usually opposite and very shortly stalked, but their more horizontal disposition in the broad-leaved plant makes the first-named character more noticeable, especially in the case of old leafy stems, on which each pair of leaves is separated by a conspicuous internode (Figure 2). In older plants of both species the lower parts of the stems are bare, and are marked by the scars of the fallen leaves (Figures 3 and 4). The stems of *A rotundifolia* are hairy and stouter than those of *A. fruticosa.* In addition, the flower buds, undersides of the petals and sepals, and often the young stems and foliage leaves, as well as being clothed with hairs, are of a reddish-purple colour in the former species. Differences are to be observed also in the shape and covering of the fruits, and in certain minor details of floral structure.

Botanical Name and Classification.

The name *Asclepias* (from the Greek *Asklepios,* 'The God of Medicine') was given by the ancients to a plant of this family on account of its supposed efficacy as an antidote of certain poisons; *rotundifolia* (from Latin *rotundus,* 'round' and *folium,* 'a leaf' means 'round-leaved'; *fruticosa,* literally 'fruticose' or 'shrubby' (Latin *frutex,* 'a shrub') fails to discriminate between the two species.

Asclepias with its approximately 250 species, of which about 100 were formerly separated under *Gomphocarpus,* is the largest genus of the family to which it gives its name, viz., the *Asclepiadaceae.* The account given below of the floral structure and pollination mechanism of the two species under consideration will serve to indicate the type of specialisation that is met with in this family. With regard to the family as a whole it will suffice to point out that it is mainly tropical in its distribution, being especially well represented in Africa; that, of the 1,700 or so species comprised within about 320 genera, the majority, unlike the two Cotton-bushes, are lianes or woody climbers; that a large number of them are poisonous; and that the presence of a milky sap or latex is very general; also that, while there are no native species of *Asclepias* in this country, the family is represented in Australia by 14 genera and some 53 species of native plants.

In addition to *A. rotundifolia* and *A. fruticosa* a third species, very similar to the latter, namely, *A. physocarpa,* Schlechtr., occurs in the South-East of this state. All three were formerly placed under *Gomphocarpus* on account of the absence from the floral nectaries of a curved horn present in other species. A fourth one, *Asclepias curassavica,* L., in which this character is present, occurs as a weed in Queensland, and, as early as 1868, enjoyed a wide distribution in that State. The same plant has been grown for medical purposes in South Australia. It is easily distinguishable from the other three Cotton-bushes, apart from the character referred to by its orange-red flowers and elongated seed pods.

Botanical Descriptions.

In the *Flora of South Australia* (page 464) the two Cotton-bushes are described by Mr. J. M. Black as follows:—

(1) *A. rotundifolia,* Mill. Shrub about 1 m. high with stout pubescent spreading stems; leaves ovate-oblong, coriaceous, 2½-5 cm. long, with very oblique lateral nerves; umbels 10-20 flowered; corolla white inside, pubescent and purplish outside; outer edge of corona-lobes higher than the inner; follicle ovoid-acuminate, about 5 cm. long, pubescent and with a few soft pines. *In flower*: April to August.

(2) *A. fruticosa,* L. Slender erect shrub, 1-2 m. high, the branches white-pubescent; leaves linear-lanceolate, 5-10 cm. long; umbels loose, 3-10 flowered; corolla-lobes white, ciliate; corona-lobes compressed, the outer edge lower than the inner, which terminates in 2 incurved teeth; follicles as in the preceding, but covered with numerous soft spines. *In flower*: November to February.

FLORAL STRUCTURE AND POLLINATION MECHANISM.

The flowers of both Cotton-bushes are borne in drooping clusters or *umbels* on peduncles which are both terminal and lateral in position. The lateral peduncles arise from the stem at a point on the node midway between the pair of opposite leaves, instead of from the leaf-axils as is more usual in plants. Such an origin is explained by assuming, either that the true point of origin is the node below and that part of the peduncle is fused with the intervening internode, as is believed to occur in the case of may *Solanaceae,* or that the peduncle really terminates the stem, the *apparent* continuation of which is actually a lateral branch, in short, that the stem is a *sympodium.* Which of these two interpretations is correct it is impossible to say.

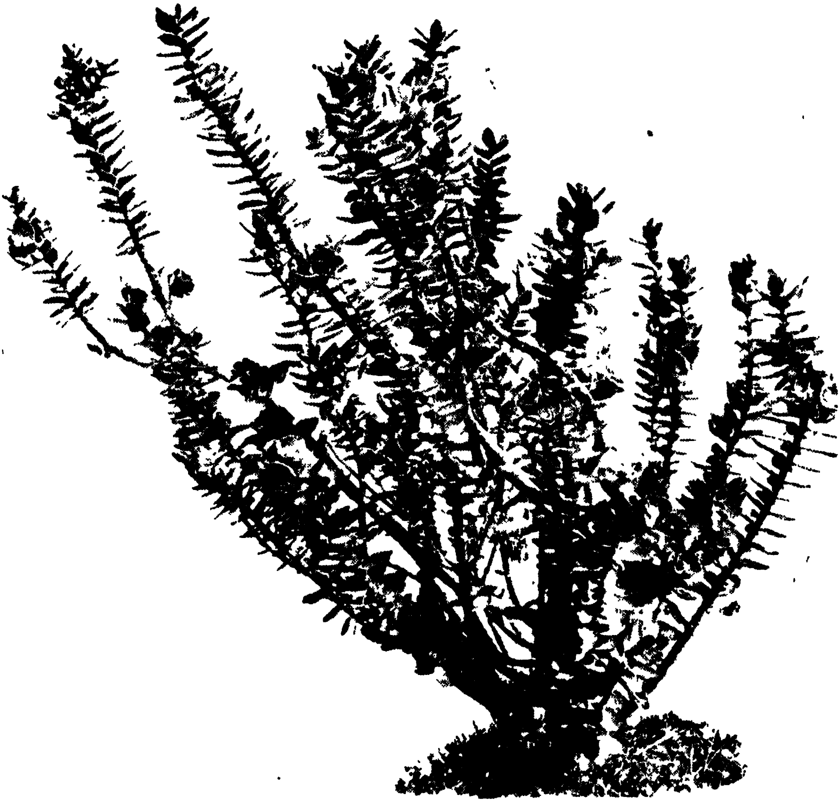

Figure 2.—Broad-leaved Cotton-bush. Single plant, showing mode of branching and arrangement of leaves on the stems.

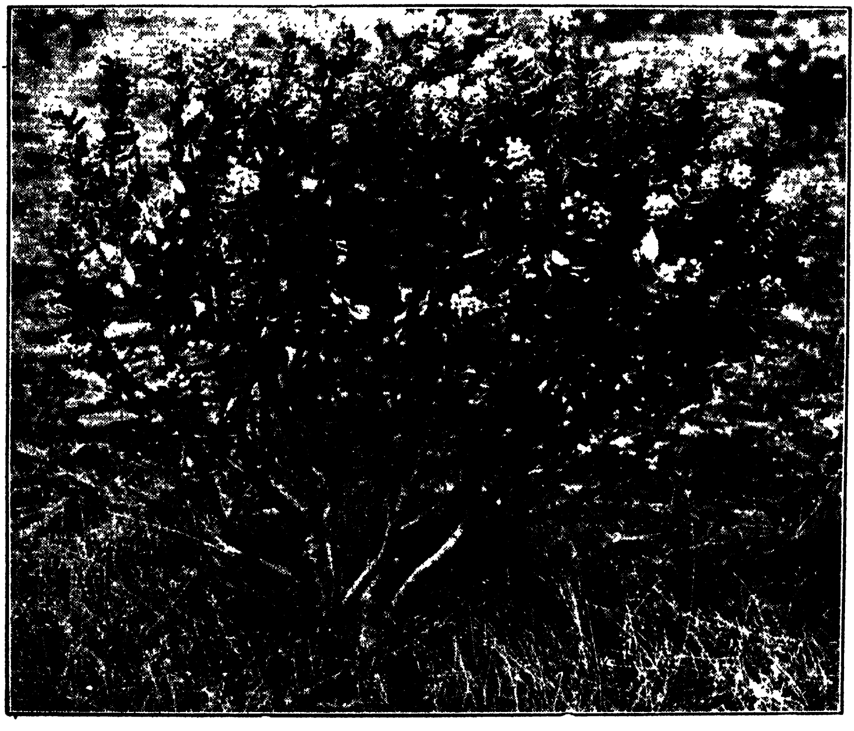
The construction of the flowers themselves, though characteristic of the Asclepiad family, is of a type most unusual among flowering plants. The essential organs, namely the stamens and pistil or carpels, are obscured by the presence of a *corona,* consisting of a series of pitcher-shaped nectaries termed *cuculli,* attached one to the back of each of the five stamens. They are further obscured by the union of the filaments of the stamens to form a structure, the *gynostegium* or column, which, in its lower part, surrounds and encloses the carpels, and, in its upper part is united with their extremities to form a terminal five-rayed stigmatic disc. With these modifications, however, the flower conforms to a simple structure plan and, except for the carpels, is radially symmetrical. The floral axis bears four whorls of parts, one each of calyx, corolla, stamens, and carpels. The number of segments comprising the whorl is five in every case, except that of the carpels in which the number is reduced to two.

The calyx is represented by five linear-lanceolate sepals which are relatively small in size and, unlike those of most flowering plants, do not enclose the flower in the bud stage. This function is performed by the corolla, the five petals comprising which subsequently separate and become strongly reflexed in the open flower. The petals remain united at the base, though their free parts are much longer than the tubular basal portion of the corolla, which is obscured somewhat by the column of stamens to which it gives o[illegible] The column is mainly composed of the united filaments of the five stamens [illegible] represents the third whorl of parts. Towards its middle it gives attachment to the corona, and slightly above this to the five anthers, while, at the summit, it becomes continuous with the stigmatic disc. The uppermost whorl consists of the two carpels. These structures are quite free from each other below and they occupy a cavity in the interior of the column; but their styles become united towards their tips and expand to form the stigmatic crown with which the staminal column is fused.



[*Photo by A. D. Cocks.*]

Figure 3.—Broad-leaved Cotton-bush. Older plant in flower, photographed in the field, showing the habit of growth.

The detailed structure of the stamens and carpels is indicated by the figures labelled B, D, E, F, and G, on the accompanying coloured plate. The essential parts of the stamens, namely the five anthers, are closely applied to the sides of the stigmatic disc in the hollows between its rays. The top of each anther is covered by a white membranous roof which overlaps the margin of the disc in this situation. The lateral walls of the anthers are purple in colour and enclose two pollen sacs or anther cells. The pollen, unlike that of most plants, is not in the form of separate grains, but resembles that of Orchids in that the individual grains are united together to form *pollinia*, or pollen masses, one such pollinium occupying each anther cell. Thus an anther, at maturity, contains two pollinia, and an elaborate mechanism has been evolved to ensure the transference, by insects, of these pollen masses from flower to flower. The presence of a column or gynostegium, the production of pollinia, and the transference of the latter by insect life, are all points of resemblance between the flowers of Cotton-bushes and those of Orchids. These resemblances are of importance, and it is worthy of note that both Asclepiads and Orchids are characterised by the development of a many-seeded type of fruit.

The inner part of the wall of each anther cell, t[illegible], the region in contact with the side of the stigmatic disc, is incomplete in its upper part, an opening being left through which the contained pollen mass is drawn when mature. Through this opening passes a structure, the *translator*, with the aid of which the pollen masses are withdrawn from the anther cells during pollination. The exact shape and appearance of the translator is shown by Figure C of the coloured plate; it consists essentially of a thread, or pair of threads (*retinaculae*), connecting the pollinium of one anther cell with the corresponding structure occupying the adjacent cell of the next anther. The middle part of this thread, or the point of junction of the two threads, is thickened to form a small body, the *corpusculum*, shaped like a narrow shield, and this is insecurely fixed to an adhesive disc situated on the column at a point midway between the two anthers and in close relation to the receptive surface of the stigma. The corpusculum occupies the uppermost recess of one of a series of small pockets situated between contiguous anthers, and appearing on the surface of the column as verticle slits bordered by tough membranes. These membranes are continuous, both with the walls of the anthers, and with the sides of the stigmatic disc in the region of its rays. The slit-like openings face upwards as well as outwards, the subjacent pockets becoming shallower towards the upper part of the column.

In the undissected flower the anthers, and the slits between them, are hidden from view by their large appendages or *cuculli*, which collectively form the *corona*, of the flower and whose relationship to the corresponding stamens is well shown in vertical section through the flower (Figure G). These structures, each of which is shaped somewhat like an inverted canine tooth, are concerned in nectar production. The presence of a curved horn in certain other species of *Asclepias* has already been referred to.

Insects are attracted to the flowers in search of nectar. In crawling over the column an insect may insert its leg into one of the slits between adjacent anthers and make contact with the translator. Should this happen the corpusculum is readily detached and the slightest traction is sufficient to draw the pollen masses from their respective anther cells. The translator threads, with their attached pollen masses, contract in such a way as to firmly clasp the insect's leg, with the result that when it leaves the flower the two pollen masses are carried with it. Alighting upon another flower the same insect may deposit the pollen masses in a position corresponding to the one from which it removed them in the previous flower so that they are brought into contact with the stigmatic undersurface of the disc.

The biological advantage of this type of pollination mechanism is worthy of consideration, since it helps to explain the efficiency and importance of the Cotton-bushes as weeds. The outstanding character of these plants is the production of large quantities of viable seeds. This character, combined with (*a*) a perennial habit, (*b*) an ability to thrive in situations of low soil fertility, and (*c*) the presence of an acrid and poisonous milky sap which renders them immune from being grazed down by stock, makes the Cotton-bushes formidable as weeds in certain situations, such as gullies and hillsides subject to being periodically ravaged by bush fires. The large amounts of seed produced, the ease with which it is dispersed by both wind and flood, and the readiness with which it germinates, gives these plants an immense advantage in competition with the native vegetation seeking to rehabilitate itself after extensive destruction by fire.

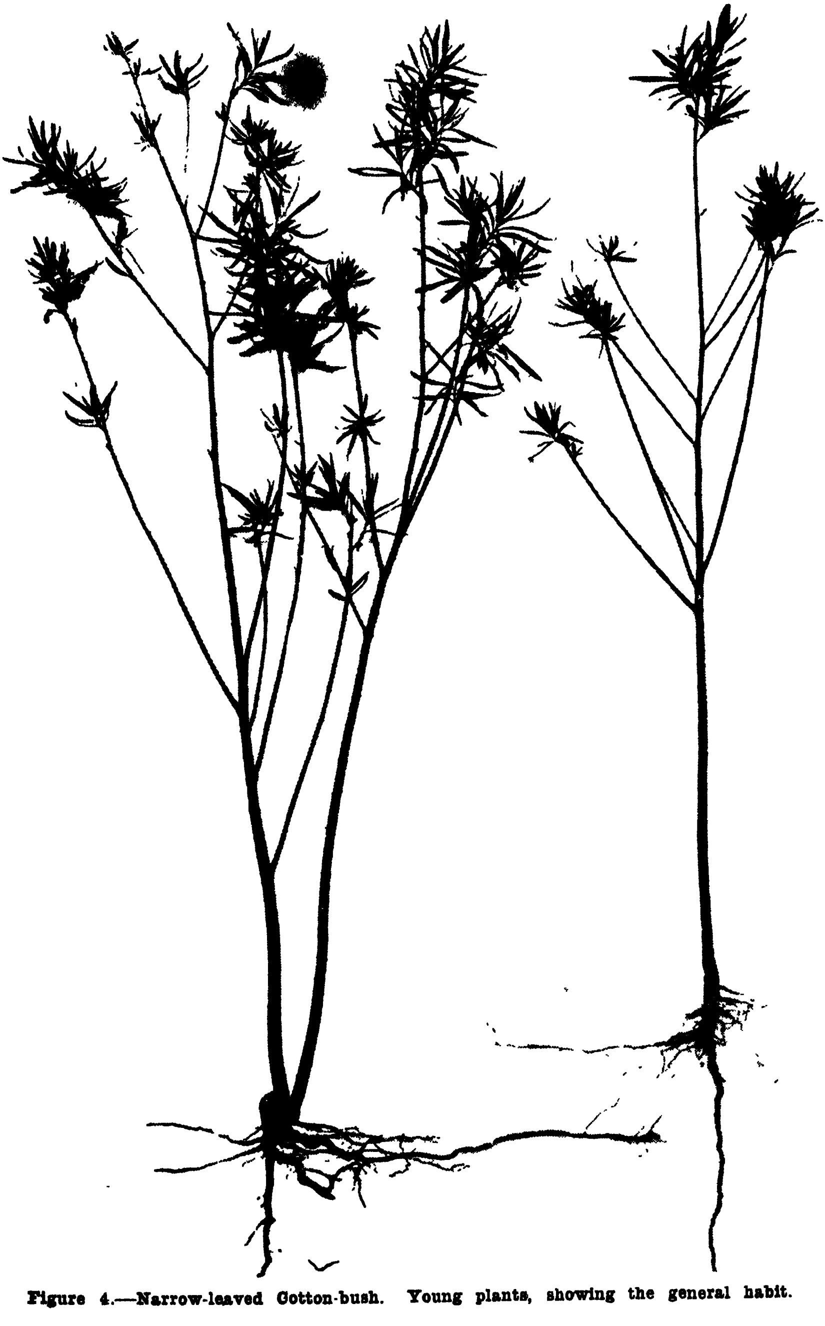


Figure 4.—Narrow-leaved Cotton-bush. Young plants, showing the general habit.

The transference of pollen in the form of masses or pollinia is related to the production of fruits containing many seeds; it ensures the fertilisation of a large number of ovules by one single act of pollination. Where the pollen is in the form of isolated grains a number of separated acts of transference may be required to bring about the fertilisation of the full number of ovules present in the ovary, since, normally, one pollen grain is needed fo[illegible]e fertilisation of each ovule. Hence if insufficient pollen reaches the stigma of [illegible]ower, only a proportion of the ovules can receive fertilisation, and the remainder will fail to develop into seeds. That this frequently happens is a matter of common experience. In garden peas, for example, the number of seeds present in the pod is subject to great variation even in the one plant. Some may have four or five, others two or three, or even one or none, according to the number of ovules which have previously been fertilised. The small white specks visible where peas have failed to develop in the pod represent the infertile ovules. By the aggregation of the pollen grains and their transference as pollinia this difficulty is to a large extent overcome. Hence the many-seeded habit of both the Cotton-bushes and the Orchids.

Unlike Orchids, however, the seeds of which are of extremely small size, the Cotton bushes produce seeds which are moderately large and apparently of high germination capacity. Moreover they are provided each with a tuft of hairs which facilitates their dispersal by a mechanism similar to that found in the Thistles. Indeed, the seed of *Asclepias* is extraordinary like the apparent seed—in reality the fruit or *achene*—of a Composite; the tuft of hairs is in every way analogous to the *pappus*, or ring of hairs attached to the fruit of a Thistle. Regarded as weeds, and from the practical viewpoint of their eradication, the Cotton-bushes must be placed within the same category as perennial Thistles; their effective control is dependent upon the prevention of seed formation. Now it is interesting to note that, just as the *Orchidaceae* is considered to be the most highly evolved and specialised family of Monocotyledonous plants, so, amongst the Dicotyledons, pride of place is usually given to the *Compositae* or Thistle family. In combining the elaborate pollination mechanism of the one, therefore, with the extremely efficient seed dispersal arrangements of the other, the Cotton-bushes would appear to have "picked the eyes," so to speak, of the two most advanced families of flowering plants.

The seeds of *Asclepias* are produced in pod-like fruits or follicles, formed by enlargement of one or both carpels of the flower. These carpels, though at first united by the tips of their styles, are otherwise quite free, and occupy a cavity in the interior of the column (Figure G). The column is soon ruptured by the growth of the carpels after fertilisation, whereupon the latter appear on the surface, and by further development and enlargement become the follicles. The mature follicle of *A. fruticosa* is more inflated than that of *A. rotundifolia* and its wall is thinner. Both are covered with soft spines which, however, are much more numerous and usually longer in the case of *A. fruticosa.* The follicle with its attached stalk representing the original flower pedicel is somewhat suggestive of the body and neck of a swan, and the structures are sometimes called "Swan-necks" by children. The ripe follicle is ovoid in shape, about 1½in. in length, and tapers to a point. The seeds, when ripe, are set free by rupture of the follicles down one side of its length.

The resemblance, as regards seeding habits, between the Cotton-bushes and the Thistles has been brought about in fundamentally different ways in the two families concerned. In the *Asclepiadaceae* the many-seeded character is actually present; but in the *Compositae* the advantages of such a character have been acquired in an indirect way, namely, by reduction in size and massing of the flowers into compact inflorescences. Actually the flower of *Compositae* produces only a single

seed; but, by the aggregation together of numerous small flowers, there results a *many-fruited type of head* which is analogous to the *many-seeded fruit* of a Cotton-bush. The likeness is completed by the assumption of similar characters by the fruits of the one and the seeds of the other.

PROPERTIES AND USES.

A very large number of Asclepiads are poisonous, and this is almost certainly true of the two Cotton-bushes.* While definite information is wanting in the case of *A. rotundifolia,* foliage and flowers of *A. fruticosa* have been shown by experiment to be fatal to rabbits. Steyn reports that forty grams of the fresh flowers, leaves, and upper parts of the stems, caused death in a rabbit two hours after administration. The nature of the poisonous principle in these plants is unknown, but the symptoms produced are those of intense gastro-intestinal irritation. Neither plant is voluntarily eaten by stock.

Apparently *A. fruticosa* has some uses as a medicinal plant. The leaves are reported to have been used as a purgative. Watt and Breyer-Brandwyk, quoted by Steyn, state that:—

> The Sutos use scrappings from the dried stem as a sternutatory in fainting and Phillips states that they use the plant as a remedy for coryza. Of recent years the powdered leaf has come into common use among Europeans as a snuff for the treatment of pulmonary tuberculosis.

The silky hairs attached to the seeds of the same species are sometimes used as kapok.

CONTROL AND ERADICATION.

Apart from their poisonous properties, the Cotton-bushes are to be regarded as undesirable plants on account of their ability to displace the native vegetation in situations where the preservation of the latter is most to be desired. It does not seem likely that either species will become a serious weed of arable land, or of pasture country, except perhaps on rocky hillsides and other inaccessible parts. But they are weeds of hillsides and gullies in situations which might with advantage be kept as public reserves and as sanctuaries for the preservation of the native flora and fauna. The narrow-leaved species does not appear to have established itself, as yet, over a very wide area, but it does occur in a few places, as, for example, along the gorge of the Onkaparinga River. The broad-leaved species does, however, cover a very large area. It occurs along the Torrens Gorge and in many other parts of the Adelaide hills and foothills. Doubtless the spread of this plant in the past has been very materially assisted by the extensive destruction of native herbs and shrubs from time to time by bush fires. The prevention of such outbreaks of fire during the hot summer months offers perhaps the most effective means of preventing the further spread of this Cotton-bush.

Eradication of individual plants, where such is required, does not present serious difficulty. Like Thistles they should be prevented from forming and dispersing their seeds. The plants should either be grubbed right out or else exhausted by repeated cutting. The Broad-leaved Cotton-bush flowers during the winter months and should be attacked during this period; the Narrow-leaved species, which flowers in the late spring and summer, is best cut down during November or December.

---

* This applies also to *A. physocarpa* (Steyn, loc. cit. page 341) and *A. curassavica* (H. R. Seddon, quoted by C. White, *Queensland Agricultural Journal*, 43, page 415, April, 1935).

VARIETIES OF WHEAT SOWN, SEASON 1935-36.

[A. W. BOWDEN, Acting Government Statist.]

1. The Acting Government Statist reports that 1[illegible] (183) varieties of wheat were sown for the wheat crop of the Season 1935-36. Th[illegible]tal acreage sown for grain, hay, and fodder was 3,210,238 (3,459,380), of which the varieties were not specified for 80,779 (106,676) acres.

2. Particulars of the most popular varieties are given at foot hereof. The first position is occupied by Ranee with a percentage of 18.09 (14.31) having displaced Nabawa which had held first place since the 1931-32 season. Nabawa ranks second on the list, its percentage being 17.56 (19.73), with Sword, Waratah, Gluyas, and Ford following in that order; Gallipoli has dropped from third to seventh position, while Merridin, a West Australian wheat, has risen from fifteenth to tenth position; Aussie and Quality also rank higher than formerly, while Currawa, Late Gluyas, Sultan, and Federation are falling back. Of the remainder Ghurka has gone from ninth to eighth place with a percentage of 3.82 (1.97), while Dan, Felix, and Florence remain about the same. In the lesser varieties Bencubbin (Early Gluyas x Nabawa) has increased from 3,162 acres to 10,462 acres, and Dundee (Hard Federation x Cleveland x Sands) showed a sowing of 8,548 acres as against only 140 last year.

3. The leading varieties favoured in each of the Divisions and their percentages to the total were:—

Central.—Sword 24, Ranee 16, Nabawa 14, Waratah 7, Ford 7, Ghurka 5.
Lower North.—Ranee 23, Sword 16, Nabawa 12, Ford 7, Waratah 6, Ghurka 5.
Upper North.—Ranee 45, Nabawa 16, Federation 5, Gluyas 4, Sword 4, Waratah 3.
South-Eastern.—Ghurka 24, Ranee 20, Gallipoli 16, Ford 9, Sword 5, Nabawa 5.
Western.—Nabawa 24, Gluyas 12, Waratah 10, Late Gluyas 8, Ranee 6, Ford 6.
Murray Mallee.—Nabawa 19, Ranee 17, Gallipoli 12, Sword 7, Gluyas 6, Waratah 5.

4. Leading varieties of wheat sown 1935-36 and 1934-35.

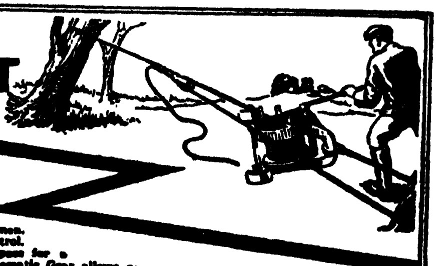
Berger's

Synthelac

'QUICK-DRYING ENAMEL'

—for cars, cycles, woodwork and furniture. Dries quickly with a long-lasting, full-gloss finish.

TEARING THEM OUT



is the regular job of the Monkey Grubber: in fact it was born to the work.

TREES and STUMPS, it matters not, they are torn out with roots intact, a thorough job quickly done. Run to the job like a barrow truck, and worked in the same manner as a boat is rowed, it develops the power of 200 men, progressively applied, and always under perfect control.

In any position, so long as the operator has space for a footing, the machine is efficiently worked. An Automatic Gear allows a load to be hauled or released at will. Besides the great power and portability there are embodied other labour saving features, such as special rope couplings, rope shortener, snatch block, etc.

Agriculturalists in Australia, New Zealand, Great Britain, South Africa, the Americas, as well as Planters in India, China, Central Africa, Fiji, the East and West Indies, recognised its merits and applied its help.

THE "MONKEY" GRUBBER

is fashioned from material mined and made within the Empire, by Empire craftsmen, to assist with the full and efficient development of Her Soil's resources.

John Short,	Hamley Bridge	(White Leghorn) ..	62	479

FEEDING TESTS AT PARAFIELD POULTRY STATION.

[New Series of Tests by C. F. ANDERSON, Government Poultry Expert.]

In continuing the experimental feeding tests at Parafield Poultry Station, a new series of tests commenced on 1st April, 1935. Five tests each of 50 white Leghorn pullets were selected. The pullets were chosen as nearly even in age, type, and maturity as was possible.

In order to gain further information on the various methods of feeding, some of the tests are similar to the series which concluded on 31st March, 1935.

The following are the methods to be adopted, together with the results from 1st April, 1935, to 30th June, 1936.

Feeding Tests commenced on 1st April, 1935.

1. Wet mash, composed of crushed barley and crushed wheat, with greenfeed and meatmeal, 2ozs. wheat per day.
2. Standard bran and pollard mash, with greenfeed and meatmeal; 1½ozs. wheat per day.
3. Bran and crushed wheat mash, with greenfeed and meatmeal; 2ozs. wheat per day.
4. Mash of crushed oats and crushed wheat with greenfeed and meatmeal; wheat, 2ozs. per day.
5. Commencing with a crushed barley and crushed wheat mash, greenfeed, meatmeal and then the feeding to be changed according to the season of the year.

	No. Eggs Laid 1st April, 1935, to 31st May, 1936.	No. Eggs Laid Month of June, 1936.	Total Eggs Laid 1st April, 1935, to 30th June, 1936.
No. 1 Test	7,893	315	8,208
No. 2 Test	8,065	334	8,399
No. 3 Test	8,700	382	9,082
No. 4 Test	7,013	238	7,251

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

CONFERENCE AT CEDUNA.

Over 60 members attended the Women's Conference at Ceduna which was sponsored by the O'Loughlin Branch on 1st July. Besides the Conference there was an exhibition of cookery, handiwork, &c., when 227 exhibits were displayed.

Miss I. Hasting presided over the Conference, and papers were read by Mrs. A. Kloeden (O'Loughlin), on ''Sauces, Pickles, and Chutneys''; Mrs. E. C. Lowe (Laura Bay), ''Gardening Notes''; Miss I. Hasting (O'Loughlin), ''Health and Figure Culture.''

Miss Ellie Campbell (Inspector of Domestic Arts, Education Department) gave a demonstration in upholstery.

Prizes were awarded to the following ladies competing in the Exhibition of cookery and handiwork:—White bread—Miss D. Kloeden 1, Mrs. Reincke 2, Mrs. A. Kloeden 3; yeast buns—Mrs. S. Trewartha 1, Miss K. Blumson 2 and 3; scones—Miss D. Kloeden 1, Mrs. R. W. Burke 2, Mrs. E. L. Lutz 3; biscuits—Miss R. Blumson 1; sponge roll—Miss I. Hasting 1, Miss D. Kloeden 2, Mrs. R. W. Burke 3; jam tarts—Mrs. A. Kloeden 1 and 2, Mrs. E. L. Lutz 3; nut and currant loaf—Miss R. Blumson 1; pasties—Miss A. Kloeden 1 and 2, Miss L. Blumson 3; ribbon cake, Miss R. Blumson 1, Mrs. C. Bergmann 2, Miss I. Hasting 3; coffee cake—Miss I. Hasting 1, Miss R. Blumson 2, Mrs. E. Pfeiffer 3; pound cake—Mrs. C. Bergmann 1, Miss R. Blumson 2, Mrs. A. Kloeden 3; cream puffs—Mrs. A. Kloeden 1 and 2, Mrs. Reincke 3; sponge cake—Mrs. E. L. Lutz 1 and 2, Mrs. Reincke 3; blowaway sponge—Mrs. S. Trewartha 1, Mrs. E. L. Lutz 2 and 3; German cake—Mrs. E. The Conference Secretary (Mrs. E. E. Lutz) was pleased with the response of members in regard to the attendance, the agenda, and the excellent display at the exhibition.

EYRE'S PENINSULA (WEST) CONFERENCE.

The Conference held at Ceduna on 1st July was one of the best attended meetings which the Bureau has had in the western district of Eyre's Peninsula for many years. Mr. J. S. Foggo (Chairman of the O'Loughlin Branch) presided, and the opening address was given by Professor Perkins, representing the Advisory Board of Agriculture.

Papers were read by Mr. J. W. Blumson (Laura Bay), on "Marginal Areas"; Mr. W. Barnett (Laura Bay), "Economic Disadvantages under which Primary Producers are Labouring"; Mr. E. R. Pfeiffer (O'Loughlin), "Sheep and Their Value on the Farm"; Mr. S. R. Morgan, "Plant Nutrition and its Practical Attainment." Questions on a variety of subjects were answered by departmental officers.

The following resolutions were carried:—(*a*) "That the next Conference be held at Ceduna under the auspices of the Maltee Branch." (*b*) "That this Conference is not in favour of a levy on wheat and wool for research and advertising purposes." (*c*) "Whereas the purchaser gets our wool packs free and one pound (draft) on every cwt. and is just as concerned in selling wool as we are, we consider that the buyer should forfeit one pound of wool (draft) allowance to cover the levy required for publicity and research purposes." (*d*) "That it be a recommendation to Branches responsible for Conferences to hold a field day in their respective districts on the day after the Conference."

Professor Perkins presented the trophies of the May District Crop Competition to the following winners:—Gaden and Linke (Koonibba), 83 points; L. Martin (Maltee), 79 points; P. Lange (Chinta), 78.5 points.

In the evening Mr. W. J. Spafford (Director of Agriculture) gave an illustrated address on his visit to countries in the Southern Hemisphere.

IRRIGATED FRUIT GROWERS' CONFERENCE AT RENMARK.

In opening the Annual Conference of Branches of the Agricultural Bureau along the River Murray, which was held for the first time under the auspices of the Block E branch at Renmark on 18th June, Mr. J. B. Murdoch (member of the Advisory Board of Agriculture) said it was to be regretted that along the fruit growing districts of the River, where conditions should be particularly suitable for the organisation of keen Branches of the Bureau, the blockers did not support the Bureau anything like so enthusiastically as the producers in the purely agricultural areas of the State. Compared with other primary producers, the lot of the River grower was cast in very pleasant places, but there were still tremendous possibilities attached to the progress in the River Murray Valley, and the onus was on the growers to try and further the well-being of the industry from which thy derived their livelihood.

The Bureau system was the vehicle by means of which they were enabled to meet together, and discuss those problems which were continually calling for solution. In concluding, Mr. Murdoch asked members to give more support to their district Branches of the Bureau.

BARLEY

We have large Overseas Representation, and are in constant touch with the World's Markets, and strongly advise Growers, before selling elsewhere, to submit samples to us for valuation.

Delivery taken at any Railway Station, Siding, or Shipping Port.

The New Farm Tractor for which you have waited

THE RD4

"CATERPILLAR" DIESEL

The Latest Product of "CATERPILLAR" Tractor Company.

The Pioneer and World's Largest Builder of Track-type and Diesel-powered Tractors.

Until the RD4 arrived, the former "Caterpillar" Thirty was supreme in the 5-6 plough field—for pulling capacity, for low upkeep, for long life. This new model is built to surpass the former "Thirty's" greatest records—and to save fuel money at a rate that no other tractor of this size has even shown.

Note certain RD4 improvements over the former "Thirty": Five forward speeds, ranging from 1.7 to 5.4 miles per hour; new automatic bellows-type dust-seals (of distinctive "Caterpillar" design), to guard final drives; improved heat-treatment of parts and final alloy steels for even greater stamina; greater compactness and accessibility; far stronger transmission and tracks. (Former "Thirtys" are still serving after 25,000 hours of heavy drawbar work. Think how much longer these more rugged new models should last.)

AND, ABOVE ALL . . .

A Full Diesel Engine Offering Huge Fuel Savings.

Write to-day for full information of either Diesel or Kerosene Models.

ADDRESS YOUR LETTER—"CATALOGUE DEPARTMENT,"

THE S.A. TRACTOR COMPANY,

Showrooms: 231, Flinders Street. Box 524E G.P.O., Adelaide.

"THERE IS ONLY ONE CATERPILLAR."

The 1936 Model

"ALFA LAVAL"

is now available.

New Design with Substantial Improvements.

Cleaner Skimming than ever.
Stronger construction.
Improved Speed Indicator.
Improved Oil Filler and Gauge.
Larger Milk Vat.

Free trial, allowance to old Separator, and easy terms.

(Incorporated in Victoria),
Box No. 365D, G.P.O. 95-97 NORTH TERRACE, ADELAIDE.

Delegates to the number of about 80 were present from Barmera, Berri, Renmark, Block E, Ramco, Waikerie, Lone Gum and Monash. The following papers were read and discussed:—"Agriculture in Germany," Dr. F. E. Meier (Renmark); "Production of Citrus Fruit for Export," Mr. R. Moss (Berri); "The Removal of Seepage Waters by Plant Growth," Mr. F. R. Arndt (District Horticultural Instructor).

Mr. A. G. Strickland, M.Sc. (Chief Horticultural Instructor) spoke on the "Investigations of the Irrigation Advisory Committee" and replied to questions relating to mottle leaf in citrus, and the application of lime to irrigated soils. Mr. W. J. Spafford (Director of Agriculture) and Mr. F. R. Arndt (Horticultural Instructor) also replied to questions. It was decided that the 1937 Conference should be held at Waikerie.

At the evening session, Mr. Spafford addressed the Conference on "A Tour of the Southern Hemisphere".

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, 24th June, there being present the Hon. A. L. McEwin, M.L.C. (Chairman), Messrs. P. J. Baily, A. J. A. Koch, A. M. Dawkins, Geo. Jeffrey, A. J. Cooke, F. Coleman, H. Wicks, R. H. Martin, S. Shepherd, W. J. Spafford (Director of Agriculture), Professor A. J. Perkins, Dr. A. E. V. Richardson (Director Waite Research Institute). and Mr. H. C. Pritchard (Secretary). An apology was received from Mr. J. W. Sandford.

New Member.—Mr. W. J. Spafford (Director of Agriculture) was welcomed as a member of the Board by the Chairman.

Congress.—The Secretary reported that Cabinet had approved of Congress to be held this year. His Excellency the Governor had consented to deliver the Opening Address.

Life Members.—Messrs. L. A. Chapple (Berri), J. J. Modystach (Wilmington), K. Jacobs (Cherry Gardens), and C. Brook (Hartley), were approved as life members of the Agricultural Bureau.

New Members.—The following names were added to the rolls of existing Branches:—Beetaloo Valley—Miss R. Curtin; Belalie Women's—Mrs. Fred. Maddock; Chapman's Bore—J. Spencer; Georgetown Women's—Mrs. R. J. McDonald, Mrs. J. A. Lyons; Mudamuckla—E. Miller; Owen Women's—Mrs. S. C. Lacey, Mrs. C. L. Marshman, Miss G. Harkness, Miss A. Harkness, Mrs. A. S. Evans, Mrs. R. McKenzie, Miss L. Hancock; Parilla Women's—Miss L. Carman; Sutherlands—P. Schiller; Warramboo Women's—Miss Melva M. Murphy, Miss C. E. Daniel; Wasleys Women's—Miss V. Currie; Yandiah Women's—Miss C. Kupke; Yurgo—Don. Martin.

Several items were taken in Committee.

FARM BLACKSMITHING.

In the course of a paper read at a meeting of the Green Patch Branch on 7th May, Mr. S. Baillie stated that the high cost of blacksmithing and the distance farmers had to travel to a blacksmith had forced many to do their own work. With a blacksmith shop most repair jobs could be satisfactorily done on the farm on days when it was too wet to work outside. The farm blacksmith shop should stand away from other buildings on account of the danger of fire. A blast could be supplied by either bellows or a forge. The latter was preferable. It took up less room, gave a good even blast, and was not likely to get out of order, as was the case with bellows. Other articles needed included an anvil, drilling machine, vice, and if possible a set of taps and dies; also some handy tools such as hand hammers (2), one 1½lbs. and one weighing about 3lbs. for heavier work, and a hacksaw. With the above tools a farmer could do most of the jobs that would arise. Either coal or charcoal could be used for fuel. Charcoal could be obtained on the farm, whereas coal had to be bought. In summer it was advisable to use coal, as charcoal gave a lot of sparks which might set fire to dry grass or old bagging close to the shop. All punches, chisels, etc. needed in the shop could be made from scrap metal bought at sales.

Mr. Baillie exhibited articles made in the farm blacksmith shop, including a welded hame-hook and eyebolt and a set of stencil plates.

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

RIVER MURRAY PRUNING COMPETITIONS CHAMPIONSHIP.

For the first time since the inception of the Pruning Competitions, the championship events were this year conducted by the Mypolonga Branch. Under the able direction of Mr. Vic. Wright, Secretary of the local Bureau, the Competitions, which were held in the orchards of Messrs. J. L. Leopold and J. Victory on 7th July, were brought to a successful issue.

Approximately 200 visitors attended, included amongst whom were Messrs. J. B. Murdoch (Member of the Advisory Board of Agriculture), H. J. Crawford, C. E. Russell, C. W. Till, W. N. Twiss (representing the Dried Fruits Board), R. Fowler (Manager of the Blackwood Orchard), J. J. Odgers, Ramco (General Secretary of the River Competitions), and F. C. Richards (Asst. Secretary, Agricultural Bureau).

Judging was done by E. Leishman, of the Department of Agriculture, and Messrs. Andrew (Waikerie), W. Noles, and B. Edson, who acted as consultative judges.

RESULTS.

FRUIT TREE SECTION.

WORMS IN SHEEP.

A reply supplied by the Stock and Brands Department to a correspondent who asks why the administration of various medicaments over a period of years has not been successful in ridding sheep of stomach worms.

Many factors are responsible for failure, such as:—(1) The drenches were not given often enough. (2) No drench is 100 per cent. effective in killing all the worms present, and furthermore, in addition to the adult worms passed, there would be thousands of eggs which, containing the larvae form of the worms, could develop in the soil, and later be picked up by the sheep while grazing, and they would then become re-infested. (3) Introduction on to the farm of sheep purchased at markets, &c. (4) The sheep, in addition to being infested with stomach worms, are most likely infested by minute threadlike worms, which live in the small intestines, and are most difficult to get rid of.

The most successful drench for stomach and intestinal worms is a mixture of Bluestone solution and Black Leaf 40, particulars of which are as follows:—Two different strengths of copper sulphate may be used, viz.:—

No. 1.—Bluestone solution, 2 per cent. strength, *i.e.*, 1lb. dissolved in 6galls. of water, in which is mixed 14 fluid ozs. of "Black Leaf 40" Solution. Dosage: Adult sheep, 2 fluid ozs. (four tablespoons); two tooths, 1½ fluid ozs. (three tablespoons); lambs, 6-12 months old, 1 fluid oz. (two tablespoons); lambs, 3-6 months old, ½ fluid oz. (1 tablespoon).

No. 2.—Bluestone solution, 5 per cent. strength, *i.e.*, bluestone 1lb., "Black Leaf 40" 14 fluid ozs., water 2galls. Dosage: Adult sheep, ¾ fluid oz. (or 20 c.c.'s); two tooths, 4-6 fluid drams (or 15-20 c.c.'s); lambs, 4-15 months, 1½-4 fluid drams (or 5-15 c.c.'s); up to 4 months, 1½ fluid drams (or 5 c.c.'s). Note.—Doses of the 5 per cent. solution vary according to size and weight.

To Prepare Bluestone-"Black Leaf 40" *Solutions.*—Use only the bright blue crystals, discarding any that are white and powdery. Dissolve the crystals in a little boiling water and then add water to make six or two gallons, according to which ever formula you intend using. Then add the "Black Leaf 40" and stir well. As bluestone corrodes metals, it should be prepared in earthenware, porcelain, or wooden vessels.

2 fluid ozs. = 4 tablespoonfuls.
1 fluid oz. = 2 tablespoonfuls.
½ fluid oz. = 1 tablespoonful (or 4 fluid drams).
2 fluid drams = 1 dessertspoonful.
1 fluid dram = 1 teaspoonful.

But it is recommended that a graduated measure glass up to 2 fluid ozs. be used, as the size of spoons is liable to vary.

The main advantage in using a 5 per cent. solution is that the dose is smaller and therefore easier to administer.

1 fluid oz. of 5 per cent. solution contains 22 grains $CuSO_4$.
1 fluid oz. of 5 per cent. solution contains 16 mins. "Black Leaf 40".
1 fluid oz. of 2 per cent. solution contains 8½ grains $CuSO_4$.
1 fluid oz. of 2 per cent. solution contains 6½ mins. "Black Leaf 40".

In using either of these solutions it is not necessary to starve the sheep beforehand. In the case of badly affected sheep, the drench should be repeated in 10 days' time and then every 28 days. If possible, after drenching place them in a paddock, which will not be used for grazing sheep, for 48 hours. By doing this your pastures will not become so heavily infested and thus reduce the chances of a massive re-infestation of sheep. Another point to bear in mind is that sheep introduced on to the farm from markets, &c., should be drenched before they arrive at the farm. In addition to any medicinal treatment, it is essential that sheep have good nutritious food, so that if the grazing is scarce it is necessary to supplement it by feeding concentrated with chaff. Provided the solutions recommended are carefully prepared in accordance with instructions, and the correct dose given, no losses will occur following their use.

DAIRY AND FARM PRODUCE MARKETS.

Messrs. A. W. SANDFORD & CO. LIMITED reported on 1st July, 1936:—

BUTTER.—Production throughout June was disappointing as, owing to the lateness of the opening of the season, the feed growth was backward and butter production was about 20 per cent. to 25 per cent. less than for the corresponding period last year. Since then the "lag" has been overtaken somewhat but is still behind 1935 figures. The London market fortunately has not slumped and at the date of report choicest Australian on spot was selling at 105s. per cwt., which compares with 87s. at this time last year. Local prices have continued fairly steady at:—Choicest creamery fresh butter, in bulk, 1s. 3¾d. per lb.; prints and delivery extra. (This price is for local sale only and, under the Quota System, the equalised price manufacturers will receive will be 1s. 2⅜d. per lb., on which basis payments to cream suppliers will be calculated.)

CHEESE.—Milk supplies to the factories are now improving each week, although in this commodity the tonnage produced is less than last year. Good interstate and local trade cleared consignments each week and there is no surplus yet available for the London market. Present prices are:—Large and medium, from 9½d. per lb.; loaf, from 10d. per lb. at store door, delivery extra; semi-matured and matured, 1s. to 1s. 1d. per lb.

EGGS.—It was expected that ere this supplies would have increased rapidly, but the cold weather has checked production and with a strong local and interstate demand the packing floors have been kept cleared. Within the next week or two, however, exporting to London will commence. Values are:—Ordinary country eggs, f.a.q., from 8d. per doz. net; selected new laid, clean eggs, full-sized, to 1s. per doz. net.

BACON.—Steady turnover in bacon took place throughout the month, although the demand for hams, as is usual during the winter, was very slow. The factories forwarded ample supplies, and all requirements were met. Best quality sides, 9½d. per lb.; middles, 9½d. to 10d.; heavy middles, 9d.; rolls, to 8d.; hams, 11d. to 1s.; cooked, 1s. 2d. to 1s. 2½d.; lard, bulk, 6d. to 6½d.; prints, 7d. per lb.

ALMONDS.—Limited supplies met with keen demand, and greater quantities could be placed. We advise consigning. Softshells and Brandis, 8½d. to 9d.; hardshells, 5d. to 5½d.; kernels, 1s. 9½d. to 1s. 10½d. per lb.; walnuts, 9d. to 11d. per lb.

HONEY.—The improved winter demand was maintained throughout the month, and supplies are now moving steadily, that is for prime quality clear extracted. Quotations are:—Prime quality clear extracted, 2d. to 2½d.; lower grades, 1d. to 2d. per lb.

BEESWAX.—Was short in supply, and buyers' requirements were only partially filled. Rates were unaltered, being:—1s. 3d. to 1s. 4d. per lb., according to quality.

LIVE POULTRY.—Auction sales are held every Tuesday, Wednesday, Thursday, and Friday at our sale rooms. The catalogues submitted throughout the month were fairly extensive, but with some purchasers having buying orders from the eastern States, keen competition was experienced, especially for prime quality, well breasted, table birds. We advise consigning. Crates loaned free on application. The following are prices realised:—Prime roosters, 3s. 6d. to 4s. 9d.; nice-conditioned cockerels, 2s. 8d. to 3s 4d.; fair-conditioned cockerels, 2s. to 2s. 9d.; chickens, lower; heavy-weight hens, 2s. 6d. to 3s. 3d.; medium hens, 1s. 9d. to 2s. 4d.; light hens, 1s. 5d. to 1s. 8d; couple of pens of weedy sorts, lower; prime young Muscovy drakes, 3s. 1d. to 3s. 9d.; young Muscovy ducks, 2s. to 2s. 6d.; ordinary ducks, 1s. to 1s. 9d.; ducklings, lower; geese, 2s. 6d. to 3s. 9d.; goslings, lower; turkeys, good to prime condition, 7½d. to 9½d. per lb. live weight; turkeys, fair condition, 6d. to 7d. per lb. live weight; turkeys, poor and crooked-breasted, lower; pigeons, 5d. each.

POTATOES.—New season's, 10s. per cwt.

ONIONS.—Brown Spanish, 10s. 6d. per cwt.

RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of June, 1936, and also the average precipitation for June, and the average annual rainfall.

Station.	June, 1936.	Av'ge. for June.	To end June, 1936.	Av'ge. Annual Rainfall.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

[The new Bureau subscription rate of 2s. per annum, which was recommended at the 1933 Congress, applies to all members as from 1st August, 1934, with the following exceptions:—Life members, Branch Secretaries, and members who reside in the same house as (a) a Life Member, or (b) a Branch Secretary, or (c) a subscribing member. Subject to the foregoing exceptions, new members joining during the months of July to December will pay 2s. per annum, and those joining during the months of January to June 1s. for that period and 2s. for each succeeding year. Subscriptions must accompany the nomination forms unless the nominee is exempt.]

THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

MEN'S BRANCHES.

POULTRY AS A SIDELINE.

[Paper read by Mr. E. W. Wilson at a meeting of the Whitwarta Branch on 4th April, 1936.]

Poultry keeping has been practised for many years. In Gent's "*Systema Agriculturae,*" published in 1675, the keeping of fowls for profit is advocated, and advice given as to management; but it contains no description of different breeds.

From a State point of view it is generally accepted that there are possibilities for further extension of poultry raising on farms where climatic conditions are very suited to the production and marketing of a perishable product such as eggs. This paper is written from the point of view of poultry kept as a sideline to general farming, not as a sole means of livelihood, as it appears that, to a large extent, the greater extension of the industry from an egg producing aspect will come from the farming areas.

In the last few years a marked expansion has taken place in the rearing and keeping of large numbers of poultry in the suburban areas. No doubt, this can be attributed to the depression and people with a block of land or two are keeping poultry in order to obtain some return. The average farmer has an advantage over the suburban producer in production costs. The land necessary for the keeping of poultry is available on the average farm; the cost of feeding is also reduced to the minimum, as practically all the food materials necessary for the production of eggs are grown on the farm. This is a distinct advantage, as the suburban man has to buy most of the necessary foodstuffs. In districts where water supplies are available and are suitable for the growing of green fodders, there is no reason why eggs of the highest quality cannot be produced on the average farm.

There is another important item regarding poultry raising, and that is the employment of the younger generation on the farm, which is worrying most of the parents at present. I believe that where boys and girls show any inclination towards the care of poultry, they should be given an opportunity of improving their knowledge. The Education Department is doing good work in this matter under the Home Project Clubs. In the Egg Laying Competition conducted at Parafield Poultry Station, there is a section for Home Project Workers, in which a number of boys from all parts of the State have birds competing, and some of the birds are recording wonderful results.

Producing eggs and marketing them continually in a haphazard way is only courting disaster. To argue that it requires special skill to produce eggs of the quality desired cannot be substantiated. Only about three years ago the settlers on the Land Settlement Scheme, under the control of the Employment Promotion Council, received their first supply of poultry, and it should be remembered that very few of these settlers had any previous experience with poultry. During the last 12 months nearly 100 per cent. of the eggs produced by these settlers have passed the grading for export. There are no statistics available concerning the average consumption of eggs in this State. If the annual consumption of eggs were only increased by a dozen per head, the increase would be equal to some 580,000 dozen and this should be easily attained if the public were assured of buying eggs which were not only attractive in condition of the shell, but of good quality.

In considering the question of keeping poultry on a farm, the principal point to be considered is the extent to which a side line can be handled on the farm without interfering with the more important work of the holding. Generally speaking it is the womenfolk who give most attention to the poultry on the farm and this fact counteracts the belief that the keeping of poultry on the farm is more or less a drag on the farmer himself. The principal question is marketing. In order to obtain best results the eggs should be marketed twice a week in the summer months. In order to make this economically possible sufficient birds should be kept so that a case of eggs can be marketed at a time, and from 300 to 350 fowls should be kept. To ensure a regular supply of eggs it will be necessary to replace a certain percentage of the flock each year. I would suggest that if 300 fowls are kept, 30 per cent. should be replaced each year. It is doubtful whether any bird after three laying seasons is worth keeping for the production of eggs only. On the majority of farms one often hears that during the months of April and May, there is a shortage of eggs. This is due to the fact that the old stock are moulting and no young ones have been reared to take their place. Until producers realise that pullets are the only class of stock that will lay any number of eggs during the winter months, a shortage of eggs will regularly occur.

Thousands of birds on farms to-day are only laying a few eggs a year. A good method of building up one's stock is to watch the flock well and cull out all the old and defective birds.

The first laying season of a hen is the most profitable one. In the second year the birds that have been proved the best layers during the first season should be used as breeders, and a portion of only the very best layers retained for the third season. No birds should be kept after the third season unless as breeders. There are numerous breeders of high-class poultry in the State, and I would suggest replacing each year a certain amount of your flocks with these, either by fertile eggs (if one possesses the necessary incubators and brooders), or by day-old chicks.

The question of breed is one that rests entirely with the farmer. Whether a farmer is going to devote his time to egg production alone or to breeding for dual purposes should also be considered. However, the capabilities of the White Leghorns and Black Minorcas as prolific layers are well known. Whatever breed is decided on, it should be the aim to raise stock that will produce 2oz. eggs, as this will be the means of keeping the stock up to a good standard. As the size of the bird deteriorates so does the size of the egg, as well as the general constitution of the bird, making the hatching and rearing more difficult.

Fowls should be always well housed in good, dry sheds, kept free from tick or lice with used crank-case oil or similar substances, and always fed in a systematic method on good wholesome feed, with plenty of good fresh water with a little iodine added to it.

BREEDING AND FEEDING PIGS ON THE FARM AS A SIDELINE.

Paper read by Mr. O. Jaeschke at a meeting of the Wirrabara Branch on 29th February. Pig breeding is one of the most profitable sidelines on a farm. One cannot expect great success without a little dairy on the farm, because skim milk plays an important part in the rearing of pigs. Therefore, the more cows are kept and the more milk there is the greater the profits. Three or four sows could be kept quite easily, and at the same time be well fed. For breeding, a large White Boar mated with Berkshire-Large White cross sows would produce a pig which would be very useful for home consumption, and for which a ready sale would be found at the Abattoirs market. When selecting a young boar for breeding, he should be the biggest and best shaped pig in the litter. He should have 14 teats evenly set and well spaced. The same thing also applies when selecting a young sow, and it is very important that she should have plenty of room between the forequarters and hindquarters. If intending to rear young pigs for breeding they should be well fed and allowed plenty of exercise. Care should be taken not to let a sow become too fat after she has been mated, especially shortly before farrowing. A sow that is too fat would have trouble at farrowing, and after farrowing would be awkward and sluggish, and consequently youngsters are often stepped on and lain on. Pigs do quite well on soaked chaff and a little grain. After a sow has farrowed her grain ration could be gradually increased. Oats, barley, wheat, and also peas are all very good; wheat being the best. All grain fed to pigs should be crushed, as they thrive better on it and it is more easily digested. Care must be taken not to give a sow long straw before or after farrowing, because the young ones often crawl underneath it and the sow lies on them, with the result that they are usually squashed and suffocated. The afterbirth should be removed as soon as possible from the sty in order to prevent the sow from eating it, which she is at times inclined to do. When the youngsters are seven weeks old the bigger ones can be taken away and fed on skim milk mixed with a little crushed wheat. About a week later the others can also be taken away and the sow again mated. As the youngsters grow bigger they can be given more crushed wheat. About a fortnight before marketing they should be given a much as they can consume. A very important food in a pig's diet is meat meal. This could be obtained by killing old ewes which are too old for any other use and boiling the meat down to a soup, which could then be fed with any grain or daily ration. Greenfeed, such as barley, wheat, &c., is a very valuable feed, especially for a sow with a litter. If pigs cannot be grazed on it, it should be cut and fed to them.

SCRUB CLEARING.

In a paper read at a meeting of the Laura Bay Branch on 11th February, Mr. M. Lowe stated that the tillage implements in use by the early settlers of South Australia necessitated the removal of all obstructions from land that was to be cropped. All trees had either to be grubbed out or ringbarked and burnt so that no stump was left. Clearing was a very slow process, as there were no grubbing machines such as are obtainable to-day. As time went on farm machinery was greatly improved, the most notable feature being the invention of the stump-jump plough. Settlers then conceived the idea of cutting trees level with the ground, and the method, known as "Mullenizing" quickly spread, because it did not materially reduce the yields, and large areas could be quickly converted to cereal growing. Settlers progressing into the lighter rainfall areas of the State discovered that the scrub, which consisted mostly of light types of mallee and titree with a few other small trees and bushes, could easily be broken down by a roller drawn by horses, bullocks, or donkeys. It was then burnt and the snags cut off. The rollers were made mostly from discarded steam boilers with a heavy framework of wood mounted on them in order to give the larger trees a lean forward, enabling the roller to travel over them and crush them. Owing to the weight that must be lifted in travelling over heavy timber, beams extending about 2ft. 6in. on each side of the roller to break down larger trees without the roller going over them, saved a great deal of power, thus lowering costs.

Teams were not a great success in the heavier types of rolling scrub. Much time had to be expended in clearing ways for them to get through, and injuries to the animals were often met with. When crawler tractors were introduced they were quickly adapted to scrub rolling, their more vital places being protected with steel plates and screens. Their ability to force their way through almost anything, together with their compactness and great power, made them most suitable for the work. The writer had used such a machine very successfully during the past year. The cost of rolling varied considerably with the type of fuel used and the type of scrub. A tractor using kerosene averaged ½gall. of fuel per acre, and 1gall. of oil per 25 acres. Owing to its initial cost, a tractor and roller would not be a paying proposition on small areas, unless the tractor could also be used for other work. For small areas of light scrub cutting seemed to be the best means of clearing, while for very heavy mallee and titree, patches of which were often met with in the district, a grubbing machine of the Trewhella type was very useful. It would remove the big stumps which did so much damage to farm implements, and which at times remained in the ground for 30 or 40 years; while the soil often drifted from around them, making it necessary to continually burn them down.

POWER FARMING.

Paper read by Mr. E. T. Sinclair at a meeting of the Wandearah Branch held on 5th May, 1936:—No man should go in for a tractor without first taking into consideration his own local conditions. After satisfying himself that a tractor would be a better proposition he must consider the following points:—(1) The best make of tractor to buy. (2) Its suitability to do the work for which it is intended. (3) Service.

My first adventure into power farming was in 1925, when I purchased a 10/20 McCormick Deering tractor, but I found for general purposes that a larger one was required to do my work, so I traded it in for a 15/30 of the same make. In 1927 I sold this tractor and let my farm for a period of four years and resumed farming operations on my own account in 1931, when I purchased a team of horses. I worked the farm with horses for two years and then sold them and bought a second hand 15/30 McCormick Deering tractor which had been in commission for four years. Tractors will not displace horses on all farms, as it is not possible to work some farms with a tractor, but where one will work satisfactorily it is an economic proposition. The cost of fuel per acre on my land is as follows:—ploughing 1s., cultivating 6d., harrowing 2d., and harvesting 9d. Oil has not been taken into account in this summary but costs me approximately £20 a year in the working of 300 acres. During the two years I have been working this tractor £5 would more than cover cost of repairs. The direct expenditure involved in fallowing, working, sowing and harvesting the 300 acres with the tractor was covered by £90 for each of the two previous years.

A lot has been said in favour of horses because the feed necessary for them can be grown on the farm, but I am satisfied that on an average I can grow 6 to 7 bags of wheat to a ton of hay, which makes my estimate of the value of the hay about £3 a ton. Where a tractor is used in place of horses, more stock can be carried on the farm, and of these I prefer sheep. The profits from additional stock contribute largely to the running costs of the tractor. No matter how much the types of horses have been improved, a horse is no stronger to-day than a similar horse was 20 years ago; whereas the present-day tractors are designed so that they will give much greater efficiency and economy than those of even ten years ago. Modern science has also made popular the use of the Diesel engine and charcoal gas among power farmers. The use of pneumatic tyres is also a contributing factor to greater economy and efficiency in farm tractors.

TIMBERING A WELL.

In a paper read at a meeting of the Warcowie Branch on 5th May, Mr. W. A. Crossman stated in timbering a new well the measurements for the timber should be taken accurately. In the case of a well measuring 6ft. x 4ft. to be timbered with split pine or sawn timber averaging 4 or 5 inches, and where the earth walls could be dressed with a pick, the timber should be 3 or 4 inches shorter each side than the dimensions of the walls, *i.e.*, 5ft. 6in. by 3ft. 6in. As each set of timber was erected the earth picked from the walls above could fall in behind the timbers. In that way very little filling, if any, would be required behind the timbers. The best tree for timbering was one that would fill about 9 or 10 inches when split and trimmed. In cutting out timber it was important to joggle out the two ends just half-way the width of the timber, and get ends and sides as near as possible to the same size. One large end of the end-piece should be placed to take the large end of the side-piece. The next tier should be reversed, with the small end of the end-piece on the large end of the bottom tier. By that method the timber would rise fairly level all round. Before timbering an old well it should be tested by lowering a lighted candle into it. If the candle would not burn, the well was not safe for a man to descend. Foul air could be removed from a well either by showering water down it, by plunging a heap of old bagging down quickly, or by means of a wind sail. A stage, consisting of a rope at each corner of the well suspended at the top and supporting a stage made to fit just inside the timbers, could be let down or up as required, thus preventing a lot of earth falling to the bottom of the well. If a well was rotten or likely to be dangerous it was not advisable to go very deep before putting in bearers. When timbering with pine, well-seasoned timbers should be used.

POULTRY ON THE FARM.

[Paper read by Mr. W. BURBIDGE, at a meeting of the Chapman's Boro Branch, on 8th June, 1936.]

The first thing that is necessary for poultry keeping is a good shed. It need not be an expensive one, but must be dry and free from draughts. Some good posts with a straw roof and iron walls (or even white-washed bags) make a fairly good and cheap wall. The roosts should not touch the side of the shed and should all be on the level, not slanting one above the other. Four posts should be put in the ground about 3ft. high, two good rails fastened to the posts, and all perches placed from one rail to the other, and fastened so that they can be easily removed for cleaning purposes. If all perches are oiled at least once a month in the winter and every fortnight in the summer, with a mixture of waste oil and kerosene, one will never have tick or lice, and will seldom have "scaly legs." The shed should face north-east if possible and have a wire-netting front or a netted yard 6ft. high.

Breed of Fowls.—If for eggs only, the White Leghorn stands on its own. If a dual purpose breed is required the utility Black Orpingtons are as good as any. Some of the newer breeds such as Minorca, Brown Leghorns, Rhode Island Reds, Barnevelders, and Welsummers, are good layers—that is, the utility strains, not show strains.)

For breeding, pick late moulters. They are always the best layers. Do not breed from hens under two years old. If one has some good hens, they are not too old until they stop laying. The male should be over 12 months old—18 months is the best age. For the light breeds mate from 18 to 20 hens to a rooster, and with heavy breeds from 12 to 15 hens per male; that is, on the free range. If shut up, have considerably less hens to each male.

Eggs that have wrinkles, that are misshapen in any way, or that are under 2ozs. should not be used for hatching. Have the roosters with the hens in the breeding season only; guaranteed infertile eggs keep longer and sell at a higher value. The best time to hatch chickens is from June to September for heavy breeds, and July to October for light breeds. Always set hens on the ground if possible. Make a hole in the shape of a saucer, and line it with soft grass or straw. When the eggs are due to hatch do not disturb the hen, and do not feed chickens until they are four hours old. The first feed should be dry bran sprinkled around; and after that cracked wheat until 6 or 8 weeks old; then feed ground wheat and bran (mixed with milk if possible). I say use ground wheat as that is grown on the farm and is equal to pollard, and cheaper. Rabbits are good feed for fowls if boiled and mixed in the mash. Fowls need plenty of shade in the summer and shelter from the cold winds in the winter.

A FARMER'S IDEAL POULTRY FARM.

[Paper read by Mr. W. J. Brook at a meeting of the Hartley Branch on 3rd June.]

Egg producing is the one activity that pays for itself on farms at the present time. No matter what other business a farmer has to attend to, he is able to keep a certain number of poultry, because they do not take much time out of each day to look after them and they will repay him doubly for his trouble.

Housing.—Before one can go into poultry-keeping to any extent at all, one must consider housing. Firstly, choose a suitable piece of ground, preferably on the slope of a hill, hard ground (not sand), as this type of soil makes cleaning of the houses easier. The best for lasting is an iron structure 36ft. long by 10ft. wide; this is ample room for 500 birds. The shed should face the east and should be netted in front with 2in. netting, with a door in one corner. Build the roof sloping with the ground, but have the ground so that the water does not lodge at the back of the shed, as this will rust the iron. The best is to trench the ground and bank it up the iron about a foot. A shed 7ft. 6in. at back and 6ft. 6in. in front provides plenty of room for the farmer to work. Suspend the perches from the roof in such a fashion that the tick or lice cannot travel up and down during the night-time. Do not have perches too close to the iron, for if a fowl lays an egg in the back of the shed it is hard to get if one has to scramble over the perches. About 3ft. from the ground is high enough for the birds to perch. One end of the shed should be divisioned off for breeding pens. Have as large a run as possible, for there is no better feed than green grass, and more eggs are obtained by letting the poultry run about.

Breeding.—The next thing a poultry keeper has to do is to select his stock. One must procure the best to get the best. Go to a good reliable breeder and buy a pen of, say, 20 hens (second year) and 2 roosters, preferably White Leghorns for egg production. The outlay may amount to a large sum, but their stock will soon be showing a substantial profit. Get some one (or better still buy a small incubator of 60-egg capacity) to incubate the fertile eggs, and select only those above 2¼ozs. in weight. In 2 or 3 years one should have sufficient numbers to sell, and the best way then is to get rid of the 20 hens one started with and use the first year pullets for breeding, thus keeping the flock young. Sell half every year afterwards (keep a few specially good ones back for breeding), and so keep up the quality of the flock. The roosters have an important part to play in so much that one bad one will spoil a year's work, and it may take several years to get back to where you started. Be careful with mating, as future results depend largely on the class of chick that is reared. The best chick is the August and September hatch.

Feeding.—Give the flock a wet mash in the morning, wheat both mid-day and evening, and keep plenty of clean water available. Give the chicks dry bran for first week, whole wheat second, and then feed the same as the older birds. Keep the chicks in a brooder until they are 2 months old, at which age they will look after themselves. Some people ration their birds, but I believe in giving them as much as they require.

Disease.—At some time or other, especially if the run is over-stocked, diseases and death will worry the farmer, as, generally speaking, he is not a veterinary surgeon and does not know what is wrong. My experience is that if a bird gets past a certain stage (*i.e.*, if they are sitting about and not feeding) it is best to cut off their heads. Some say that is wasteful, and try to cure them, but to give the right medicine at the right time for the right disease is more than most people can do. Perhaps by keeping that bird closed in with the others you are spreading some disease, and may ultimately lose most of the flock, whereas by killing one bird you may check that disease. Roup is one of those bad diseases that requires careful treatment. In all diseases prevention is better than cure. Generally speaking, if a bird is cured of roup she will spread the germs later on through the flock, and once it gets a good hold it is difficult to control. Once or twice a week the farmer should examine his flock as he lets them out in the morning, and see if each individual bird is looking quite healthy. If he detects anything at all the bird should be caught and shut up for close observation. By so doing one can soon learn by appearance what is wrong and treat it accordingly.

I do not agree with keeping poultry shut up the whole time. One may get more eggs, but the time taken in looking after them and the toll of disease more than absorbs the extra number of eggs and leaves the farmer worse off. There are a number of foods on the market, and these may be used to advantage for the closed-in bird, but they are unnecessary for birds that are running out.

One point to remember to help make poultry-keeping a success is to have plenty of good water in the summer time. This can be done by having a tank close handy and pipes laid underground to cement troughs. Do not run heavy and light breeds together, as they require quite different methods and the two do not thrive together. One, a lighter bird than the other, will eat more quickly, so the slow eater does not get as much food as is necessary, and they don't seem to agree, the light bird having the advantage in every way.

ECONOMICAL FEEDING FOR EGG PRODUCTION.

In a paper read before a meeting of the Meadows Branch on 2nd June, Mr. S. Eyles of Clarendon stated:—

I have been feeding sprouted wheat for over three years now. This is economy, because 1¾ozs. is ample instead of the usual 2ozs. (all weights mentioned are dry weights), so that there is a saving of 1bush. in every 8bush. For each 100 fowls allow 8½lbs. of wheat per feed; that is, 17lbs. of wheat per 100 fowls per day. Soak the wheat for 24 hours in water; then drain water off, move the wheat into a dry box or old tub, and allow it to sprout for another 48 hours. It then should have a shoot and root on it. It is now ready to mix for feeding. Put it in the mixing trough and sprinkle about 1 pint of water to each 10lbs. over it. Use the water that the wheat was soaked in; there are good minerals in it. If you have any over use it on your cabbage plants, it will do them good. If you have skim milk, use that in preference to the water. Allow 14 per cent. of meat meal to each 8½lbs. of wheat, 4ozs. of linseed meal, and ½oz. fine salt. Either dissolve the salt in the water or thoroughly mix it with meat meal and linseed. Do not put salt in the water in which you soak the wheat, as it will retard the growth of the germ. If you are using "M.A.B." meat meal, you will not need any bone meal; if not, I would recommend 2ozs. of bone flour. Thoroughly mix the whole together and you will find that the meat meal, etc., adheres to the wheat. Mix the evening feed in the morning and the morning feed in the evening. Pack it up into as small a heap as possible and cover with two bags to keep the moisture in. It will be a nice, warm feed by the time you are ready to use it. In the summer it will be too hot, so spread it out, but keep it covered to keep it moist. This method of feeding must be fed the same as wet mash in troughs, allowing plenty of trough room, about 5ft. to 6ft. troughs per 100 birds.

Do not attempt to change over to this system until August, and then change gradually; otherwise you may throw the birds into a moult or put them off laying. There is no reason why one should not prepare for it now by starting to sprout the wheat. One can gradually change over by feeding a little sprouted wheat mixed with dry wheat, or else put a little in the troughs. The fowls will prefer it to the dry, once they get the taste. No harm will be done to the birds; but do not rush any change.

When it is desired to change over and cut out the mill offals after they are used to the sprouted wheat, cut the mash down gradually and replace it with the sprouted wheat, only do not put the full amount of meat meal, etc., with it at first. Gradually work up the quantity. I recently changed the feed and took 4 weeks to do it. Go through the fowl-house before feeding the mash, and give for a day or two just a little plain sprouted wheat; then carry on with the wheat and meat meal steadily. The fowls will not appear satisfied when one changes over at first, so allow a little extra until there is a little left. When they are used to this feed 8½lbs. will be quite sufficient for them. Make your own measures for the feed. It is convenient to have a bucket for each pen, as the bulk varies according to the weather, and also some grain swells more than others. If at any time—and there are times—the birds do not clean up the feed, say, in 30 minutes, take it away if it is hot weather, and dry it on bags as soon as possible. At this time of the year it will keep for the next feed. Do not mix any left with the bulk of your feed. Put it in one bucket, as it may go sour. Make sure and keep the mixing trough clean. I brush mine out after each mixing. I am now using 50 per cent. barley with my wheat. This necessitates 1 per cent. extra meat meal, as barley is more fattening.

Give greenfeed at mid-day; not more than 1¼ per cent. per bird. The sprouted grain is partly a greenfeed. If any fowls should be poisoned, give them about 5 or 6 lumps of Glauber salts, dry, put them in a quiet place, and feed them a few hours later with soft milk food. Repeat the salts in 12 hours if necessary. Since I have been feeding this way the general health of my fowls has never been better. I have 60 4-year-old breeders, and I was without eggs for 18 days only. The moult has been quicker than usual. The egg yield has been quite satisfactory; in fact, when I started in February they were laying a few less each day, but after I got going they came back and laid

PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1936.

Eggs for Hatching and Day Old Chickens

WHITE LEGHORNS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.
DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

BLACK ORPINGTONS.

EGGS.—10s. per Setting of 15 Eggs. Incubator Lots, £2 per 100.
DAY OLD CHICKENS.—17s. 6d. per dozen; £4 per 100.
COCKERELS (Specially Selected), 21s. each.

RHODE ISLAND REDS.

EGGS.—10s. per Setting of 15 Eggs. Incubator lots £2 per 100.
DAY OLD CHICKENS.—17s. 6d. per dozen; £4 per 100.
COCKERELS (Specially Selected, 21s. each).

LIGHT SUSSEX.

EGGS.—10s. per Setting of 15 Eggs.

BLACK MINORCAS.

EGGS.—7s. 6d. per Setting of 15 Eggs. Incubator Lots, 30s. per 100.
DAY OLD CHICKENS.—15s. per dozen; £3 10s. in lots of 100.

Free on Rail, Salisbury.

DELIVERY.—CHICKS—July to September.
EGGS—July to September.

Intending breeders should realise the importance of establishing their flocks with only the very best of stock, also pay particular care to the size of the egg. The future of the poultry industry in South Australia is almost entirely dependent on the export trade; the size of the egg for export is of the greatest importance. The breeding stock at Parafield is carefully selected and every egg set or sold is of a minimum weight of 2oz., and a large percentage considerably over.

All Eggs and Chickens sold from Parafield Poultry Station are guaranteed to be produced at Parafield.

EARLY BOOKING IS ADVISABLE.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury, or Poultry Expert, Department of Agriculture, Flinders Street, Adelaide.

C. F. ANDERSON, Poultry Expert.

a few extra each day for a time. When trying out this method start on one pen at a time and make comparisons. More eggs can be obtained by increasing the meat meal. but the health of the fowls will suffer. If one gives less than the amount stated the birds will become too fat. Feed about 10 per cent. of barley even in the summer to provide the necessary roughage. This feed may be fed to chicks at 8 weeks old; of course, by a gradual change, and not quite so much meat meal; try about 7½ per cent. Following is a comparison of the cost of feed for 100 birds fed on the above system and on mill offals at prices advertised in the May issue of the *Red Comb News*:—

	s.	d.
Allowing mash (at 2d. per bird) at 1s. 3d. per bushel—12½lbs.	0	9½
Allowing mash (at 2d. per bird) at 1s. 3d. per bushel—12½lbs.	0	9½
Allowing meat meal 10 per cent., at 17s. per bushel .. .. say	0	2¼
Feed as above	1	9¼
17lbs. wheat, 1s. 1d.; 1¾lbs. meat meal, 2¾d.; linseed meal, ½d.	1	4¼
	s.	d.
Saving per 100 birds	0	5

That would mean a saving of £7 12s. per 100 birds per annum.

PIGS AS A SIDELINE.

[Paper read by Mr. D. H. CHEETHAM at a meeting of the Hilltown Branch on 2nd June.]

If pigs are kept in small paddocks and have exercise, they do much better than if shut up in sties.

Breeds and Breeding.—The Tamworth is a good bacon breed; the sows are good mothers, give a good supply of milk to their young ones, and do not scald in the summer time, which is such a drawback to the white breeds. In fact I have had white pigs die from excessive scald in summer time, and others which would not grow for months on account of sun-scald.

It should be the object of a pig breeder to get 2 litters each year from a sow. This can be accomplished by weaning at 8 weeks and getting the sow in pig again in 2 or 3 days from weaning time. A sow will sometimes come in season about 3 days after farrowing, but it is a mistake to breed her at this stage, as rearing a family of from 7 to 12 is a full-time job. Litters seem to do better if born in autumn or spring, rather than when it is too hot or too cold, as in summer or winter.

Housing and Accommodation.—Pigs are destructive if running loose, and are rather severe on fences unless the fences are specially erected for them of a material such as 8-wire ring-lock fence, with a barb at the bottom and another barb about 8in. above the top of the woven plain wires. This makes a good fence if the wooden posts are placed at every 12ft. or 15ft. Sties must have either wood, concrete, or bricks for floors. Old railway sleepers make first class pig floors. Concrete and brick are both cold, even with the addition of straw. When pigs are run in small paddocks, straw sheds, made of rails and forks and covered with small straw stacks, are very suitable, and the pigs find that an earth bed is first class if kept dry in winter time. Old tanks cut in half and covered with straw make good houses. If it is possible to have a paddock of established lucerne well fenced and the pigs run on this in summer it will be found that it saves a lot of grain and keeps the pigs healthier. This method is used in the Argentine, where pigs are run in herds of thousands.

Feeds and Feeding.—The best feed for a sow after farrowing is pollard and skim milk or pollard and meat meal. A sow does a good deal better with her litter if she is in a small paddock rather than in a sty, as the lack of exercise and close confinement of a sty sometimes upsets a sow, and she will start to eat her pigs; also she likes to get away from 8 or 10 small editions of herself and lie down in peace and quietness for a while. At about 3 weeks of age the suckers will start to look for something in addition to their mother's milk. Whole-wheat put down where they can find it will soon keep them busy chewing and growing. Any of the usual grains, either soaked or crushed, are suitable for feeding growing pigs, but something, such as skim milk or meat meal or linseed meal, should be added to balance the feed and give a sufficiency of protein. Whatever grain is used should be supplemented by a liberal allowance of greenfeed and some mineral mixture, such as super and salt. Wood ashes and charcoal also will be appreciated. Six months is the objective for bacon weight. To do this the pigs must be kept growing all the time without any check.

Sickness.—So long as pigs have a dry, warm place in winter in which to sleep, a cool place to lie in on hot summer days, and a wallow throughout the summer, there should not be much bother with sickness. Worms are about the only trouble, and these affect suckers and weaners more than grown pigs. An effective and cheap remedy for worms in pigs is bluestone.

When pigs are shut up and fed on grain alone and have insufficient exercise, they may develop constipation. A dose of Epsom salts, followed by a regular supply of greenfeed, should effectively remedy this trouble. Pigs appreciate a little clean, raw meat occasionally, and it seems to do them good.

Marketing.—Porkers should be ready at 4½ months and baconers at 6 months. Local markets, that is, Adelaide, are pretty fully supplied, and for any extensive expansion of the pig industry we must look to the export buyers who, fortunately, have been operating for some time. Prior to 1930 the Adelaide market averaged about 1,000 pigs a week. Since the fall in the price of grain and the subsequent use of large quantities as pig feed it is quite usual for 2,000 to 3,000 pigs to be offered and sold at a weekly market at the Abattoirs. This would have left the pig feeders in an awkward position if the export buyers had not stepped in and bought up the surplus over local requirements.

PIG RAISING AS A SIDELINE.

In the course of a paper read at a meeting of the Cambrai Branch on 3rd June, Mr. J. Starick stated:—

The two essentials are breeding and feeding. It is no good having a well-bred pig and not feed it properly.

Type.—We should aim at producing the pig that is required for export, *i.e.*, long and deep sides, big hams, and light shoulder.

The pig that comes nearest to these requirements is the Large White. I prefer breeding from a half-bred Tamworth-Large White sow mated with a pure-bred Large White boar.

Some farmers are still breeding Berkshires, and say, "What was good enough for my father and grandfather is good enough for me." That is not so. We must try and produce a pig that the consumers overseas want, and not try and force a type on to them which they do not want, because that is a sure way of killing our export trade and consequently our own local market.

Breeding.—A young sow should not be mated until she is 8 months old, so that by the time she farrows she would be 1 year old and should be almost fully developed.

A sow which rears less than 8 piglets is hardly up to standard and if she persists in rearing less, one should get rid of her. Suckers should be castrated at about 4 weeks.

Feeding.—The feeding of sows needs special attention. They should not become fat and lazy before farrowing. It is while in this condition that the sows tend to crush the little piglets. Do not feed the sow on anything strong for 12 hours after farrowing. Feed only on sloppy food such as bran and milk; this also helps the sow to milk well. One cannot set down a hard and fast rule as to how much a growing pig should eat. A safe rule is to feed as much as they will comfortably clean up.

To put porkers weighing 70lbs. on the market in 3½ months and baconers weighing 120lbs. in 5 months should be the aim of all pig breeders, and to do this they should be forced from the time they are born. The earlier one can get the pig on the market the greater the profit.

Grain should be fed crushed (dry for preference), soaked or whole, but not boiled. Boiled grain probably looks better but is not so nutritious. Wheat and barley are fairly equal in feed value and also in price. If skim milk is available, no meat meal need be fed.

A lucerne patch should be maintained so that greenfeed can be fed to the pigs. This is a cheaper food than grain, and it helps to keep the pigs in good health. When trapping rabbits, never throw them away. Boil them for the pigs, they relish them. There is no need to clean the rabbits before boiling them.

The profits from pigs are not particularly great in our district because of the lack of some important facilities, such as cheap freight, and more important still, lack of grazing paddocks.

Whether to sell pigs as suckers, porkers or baconers, is a matter of opinion, and is largely governed by fluctuating prices. At times it is possible to buy, say, porkers at almost the same price as suckers. It takes about 5bush. of grain to feed a pig to the porker stage and about 10bush. to a baconer. If grain alone is fed with wheat at 3s. it amounts to 30s.; the price of the sucker is, say, 10s.; making a total outlay of 40s. If a baconer realises 50s., we are making a profit of 10s. per head, or 4s. per bushel for our wheat. It takes approximately 4lbs. wheat crushed to produce 1lb. live-weight; 4lbs. wheat soaked to produce 1lb. live-weight; 5lbs. wheat, whole, to produce 1lb. live-weight.

Ailments.—A common ailment in pigs is mineral deficiency, but our trouble is to find out which particular mineral they are deficient in. However, by feeding one of the following mixtures this can generally be overcome:—

Mineral Mixture 1.—Charcoal, 40lbs.; bonemeal, 20lbs.; salt, 20lbs.; phosphate, 10lbs.; molasses, 10lbs.; sulphur, 5lbs.

Mineral Mixture 2.—5lbs. meat meal to 100lbs. grain; a little slaked lime and charcoal.

Mineral Mixture 3.—1 teaspoon of bicarbonate of soda per day.

The symptoms of mineral deficiency are:—Weak in hindquarters, or, when walking, the pigs may duck as if going under a fence.

Parasites.—Another trouble is "worms." This is a little harder to deal with than the other. The remedy is as follows:—Starve pigs for 24 hours and give oil of chenopodium—8 weeks old, 20 drops; 10 weeks old, 25 drops; 12 weeks old, 30 drops; 6 months old, 1 teaspoon. Follow this up with a dose of raw linseed oil—2ozs. for small pigs and 4ozs. for larger pigs. The above should be repeated in 10 days.

For Tick.—Pour a quantity of old crank-case oil over the pigs.

Mange.—A mixture of raw linseed oil, phenyle, and flowers of sulphur.

Fleas.—Crude oil.

Cost of spraying works out at about 1d. per 7 pigs.

The scales should be used frequently to determine whether certain pigs are growing as they should.

PIGS ON THE FARM.

In the course of a paper read at the June meeting of South Kilkerran Branch, Mr. J. C. Scott-Todd stated:—

The Management of Pigs.—A great deal of success or non-success in pig keeping is due to attention to details or the want of it; it is a sideline which cannot be made by lax or irregular attention. It is a recognised fact that pigs are one of, if not the best, sidelines on the average farm. Especially so in view of the small amount of capital involved in the purchase of foundation stock and the very small outlay required for the housing of the animals.

Members who have tried pig raising without profitable results are prone to condemn the business rather than condemn their own want of, perhaps, experience, patience, and attention to details.

In a number of cases, the setbacks that pig men have received were due principally to the tendency, when pigs were bringing good prices, to rush in and buy young stock at prohibitive prices, feed them up without considering any details in respect to cost, and then be unfortunate enough to sell in a glutted market.

Breeding.—This very unfortunate happening can to a great degree be avoided by the farmer breeding his own stock in a number that is in keeping with his ability to hold them, rather than sacrifice them on a flat market, or on account of scarcity of feed.

To be able to carry out the breeding of one's own pigs, not less than four sows should be kept; and whatever breed one fancies, trueness to type will pay every time.

Of course, a number of farmers do not feel disposed to pay high prices for brood sows, and consequently they use whatever kind and shape is available, not realising that it takes less feed to keep a good animal than it does to tolerate a mongrel, and in addition the result of mongrel-breeding is apparent in the uneven litters, weakling pigs, rainbow colours, and continued bad doers. If, however, one is prepared to breed with any sows available, it is possible to counteract the ill-effects to a great degree by using a good boar. With a good sire, proper attention to culling, and a determination to avoid in-breeding, one can ultimately produce litters that will show adequate returns and a great saving in the feed bill.

A great diversity of opinion is held in regard to the proper age at which to mate maiden sows; but the greatest mistake that one can make is to breed from sows at immature ages.

Well kept young sows may show signs of heat at about 3 to 4 months, but every care should be taken not to breed at that age, for no good results will be obtained. It has been found repeatedly that this practice has led to the birth of small, weak litters, which in most cases are not worth the time wasted; and the bodily strain on the young sow has been apparent in the subsequent litters.

On the other hand, one can breed with sows that are too old, in that they are inclined to be less tolerant mothers, and are not such good doers as younger sows. Therefore a maiden sow that litters about 10 to 14 months old will assuredly give the most satisfactory results.

After the birth of the litter, and after details of the disposing of after-birth, etc., have been carried out, the sow should be disturbed as little as possible.

The young pigs can be satisfied with their mother's milk for three weeks; then arrangements should be made, so that a weak mixture of pollard and milk can be fed to them without interference from the sow, but on no account should the young pigs be over-fed, as they are easily upset, and every setback they receive at this age has a serious check on their development.

At about 4 to 5 weeks castrate the pigs so as to give them at least 2 weeks on the mother before weaning, for the check on them is not so great as when they are operated on and straight away deprived of their natural food.

In regard to the boar, procure as good a boar as is possible, and on no account breed from him under 6 to 8 months old. From that age onward he is full of vitality and can be safely used up to the age of 4 years, when he should be displaced; for from that age he will become sluggish and at times inclined to be savage.

Breeds.—The question of the best breeds to keep and the system of marketing is a matter that the individual farmer must study to make possible the best results.

The Duroc sow crossed with a good Berkshire boar will produce good litters and pigs that are saleable at any time. There are possibly other breeds that may prove to be of equal commercial value, and here again the pig raiser should keep in touch with and study the prices obtained at the local markets.

Marketing.—Taking into consideration the requirements of buyers and the most advantageous sales for the seller, with weaners at from 18s. to 22s. per head a good sow will return from £12 to £15 per year, which, with the initial costs, time, and handling, is the most profitable manner in which to dispose of one's surplus young pigs. If, however, it is desired to hold with the object of fattening, the best policy is to hold until about 7 months, when under proper conditions one should have prime young baconers of around 200lbs., which would give a dressed carcase of 150lbs. to 160lbs. This class of pig invariably brings good prices, and in comparison to heavier pigs the profits will be greater, when one takes into consideration the time, attention, and feed consumed by holding them for a longer period.

Feeding.—Cracked grain, soaked, is one of our best foods; the short period required for soaking will not have the tendency to sour the food, as is likely with the time required for soaking whole grain.

Only enough feed should be soaked to carry one from day to day. An ideal feed is to mix the available milk with the cracked grain and use it at the following meal time. Pollard with skim milk is good for suckers and weaners; it supplies the essentials to build up the young bodies without having a tendency to overdo the fattening process. Young sows that are being held for breeding purposes should not have much milk from 4 months onwards, as the fat generated inside has a detrimental effect on organs and the vitality of the sow.

PIG KILLING ON THE FARM.

[Paper read by Mr. E. Brokate at a meeting of the Springton Branch held on 3rd June, 1936.]

The most suitable pig to kill on the farm is the Large White-Tamworth or Tamworth-Berkshire cross. The Berkshire pig itself is a waste of time and money to kill for farm use because the meat, ham, bacon, etc., have so much fat that the bulk of the people are unable to eat it, and there is, therefore, a lot of waste. Other breeds, especially the Large White and Tamworth, are very evenly balanced in regard to lean and fat. A pig dressing about 200lbs. is the most suitable weight for killing, because it gives a fair proportion of everything, the hams and bacons are a nice size, and the meat itself is good and tender. I prefer killing early in May if the cool weather has set in. By doing so one will have ham and bacon to eat throughout the winter months when one can enjoy them.

A pig should not be given grain of any description within 36 hours of killing, milk only; and nothing at all within 24 hours of killing. This makes the cleaning of the runner much easier and not so liable to break.

Always kill in the morning; then the pig is left hanging until next morning, when it is cut down and taken inside, cut up and sorted for the various things to be made, such as hams, bacons, rice and liver sausage (known as black and white pudding), metwurst, brawn, and pickling meats.

When cutting up the pig, cut out the backbone first, cutting off all meat and fat, the bone itself being cut into smaller pieces for pickling. Then the ribs are taken out, leaving as little meat as possible on them. These are then cut into smaller pieces, also for pickling.

The hams are then cut off and trimmed, and the bone cut off below the first joint, which has a lot to do in keeping the hams. The required number of bacons are then cut out, preferably not too wide, about 9in. or 10in. The shoulders are generally kept for roasts, but put one into pickle to be smoked, and use it as ham. The head is cut into small pieces, and all goes into sausage. I have cut off a hogshead, which I use for pickling, and find it very suitable.

The hams are treated first. Get a pointed stick—or a steel will do—and poke holes in the skin to make sure that the salt or brine penetrates properly. Before putting the hams in rub a mixture of 1 part saltpetre to 10 of salt well into the hams. Then put all meat, etc., in layers on top of the hams and sprinkle the mixture over every layer of meat, and finally the bacons, which are rubbed with the mixture first, and then put in with the lean downwards, and more of the mixture sprinkled over them. Four or 5 days later any fluid that has accumulated at the bottom is drained off and there is then added a salt brine which has been prepared previously by boiling the water and adding enough salt and a little saltpetre to float an egg. The brine must be perfectly cold before being poured over the prepared meat. The hams are left in pickle for five weeks and the bacons four weeks, but they must be turned several times during that period to make sure they are well pickled. They are then hung up until dry before being smoked, which takes about 4 to 5 days.

Sausage Making.—The head (which has been previously cut up), the liver, all meat that has any sign of blood, and the pieces of skin from various parts are all boiled until tender; then they are sorted for rice or liver sausage. The liver and all meat with plenty of fat are then minced up with a small onion. Add salt, pepper, thyme, a little mixed spice to taste, and fill into runners. This is called liver sausage or white pudding. The rest of the meat is then minced up and mixed with rice (which has been boiled), salt, pepper, marjoram, mixed spice, cloves, and a little blood which has been saved when sticking the pig. It is then ready to be filled into the runners. This is called rice sausage or black pudding. All sausage must be simmered for about 20 minutes. If brought to boiling point they will burst, with a lot of waste resulting.

The next process is the making of the metwurst. Take ½lb. of beef (good) to every pound of pork and put it through the mincer twice in order to make sure it is fine enough. It is then well mixed, and the following ingredients added:—Salt, pepper, sugar, saltpetre, and a little garlic water to taste (the garlic is well bruised and then a little water added). It is well mixed again—this cannot be done too often—and then it is filled in the bungs and hung up in the smoke-house for a day or two, when it is ready for smoking, which takes approximately 2 days.

For the brawn, take the trotters and the tail and boil them in salt water until the meat leaves the bones. Just before taking off add 1 cup of vinegar. Take the meat off all the bones, cut it up, and put it in basins to set, when it is ready for use.

THE PHYSICAL AND CHEMICAL SIDE OF FARMING.

In the course of a paper read at a meeting of the Coonalpyn Branch on 3rd June, Mr. A. Chandler stated:—

Cultivation.—Perhaps the most important effect as far as this district is concerned is the conservation of moisture. The moisture in the soil escapes in two directions—upwards and downwards—and as we have little or no control of the downward loss, we can disregard that part.

Few people realise that a tremendous quantity of the moisture in the soil (even the moisture that is deep down in the soil) is lost by evaporation from the surface. How does this water reach the surface? Some say that the sun "draws" it up. This is quite wrong, for if such were the case cultivation would be useless as far as the moisture conservation is concerned. The water travels upwards of its own accord, and when it reaches the surface, the warmth of the sun changes it into water vapour, which, being lighter than air, floats away. The action of the water rising in the soil is known as capillary action, and is due partly to the surface film, which is present on all liquids. The more compact the soil, the easier it is for the water to rise to the surface. By keeping the surface soil loose, the water is, to a great extent, prevented from rising.

Manuring.—Manures and fertilisers are applied to increase the supply of plant food in the soil. There are 10 inorganic elements necessary for a plant to grow, viz., carbon hydrogen, oxygen, nitrogen, sulphur, phosphorus, iron, magnesium, potassium, and calcium. Continual cropping, especially with similar crops, reduces the supply of plant food in the soil, and, to keep his land in good order, a farmer must put into the soil as much plant food as his crops take out.

Artificial manures are mainly used because of their convenience and also because a farmer can choose the plant food that will benefit his crop in some special way. The plant foods mainly used by crops are phosphates, nitrates, and potash. Each of these affect a plant in a different way. Phosphates supply phosphoric acid, which helps in the ripening of the plants (mainly). Nitrates supply nitrogen, which is the most important of plant foods, as it produces a healthy growth. If there is much present in the soil a vigorous growth results. Potash produces starch, sugar, and fibre. Farmyard manure contains all of these plant foods, and is very valuable; wet seaweed is equally valuable. The principal fertiliser used in wheatgrowing is superphosphaate. This supplies the phosphoric acid, which helps the ripening and therefore produces good grain. Superphosphate originates in the sea, where various types of small sea animals feed on smaller organisms rich in phosphates, thus storing up their supply of phosphate. These animals are devoured by fish, which in their turn are devoured by sea-birds. Millions of birds devour enormous quantities of fish, and, as a result, large deposits of bird manure, called guano, accumulate. The phosphoric acid in this guano dissolves in the limestone underneath and forms phosphate of lime or phosphate rock. This will not dissolve in water, and is therefore of little value as a fertiliser. When it is treated with sulphuric acid, it is converted into superphosphate and becomes a very valuable fertiliser. Sulphate of ammonia supplies nitrogen to the soil, which produces a vigorous growth. This fertiliser is obtained as a by-product in the manufacture of coal-gas.

Lime does very important work in the soil. It loosens up sticky soil and also tends to bind up loose soil. It is not a manure, because it supplies no plant food, but it neutralises or kills the acid which is formed when vegetation decays or when artificial manures are applied, thus preventing the soil from becoming sour. It also helps the work of all fertilisers. Much of the plant food is insoluble and of no use to the plant. The lime acts chemically on these substances and changes them into available plant food.

We have discussed the fertilisation of the soil as far as the chemical treatment is concerned, but there is another important method which has been practised for many centuries, namely, the rotation of crops. In districts such as this, rotation is not carried out so intensively as in more favourable districts and in other parts of the world. In fact, much of the rotation here is practised mainly for the prevention of disease.

It is well known that crops of a like nature, such as wheat, oats, and other cereals, take the same types of plant food from the soil. These are known as exhaustion crops. Other crops, such as peas, beans, and root crops, are known as restorative crops, because they restore the main plant food to the soil in nitrogen.

The air consists of four-fifths nitrogen, and although plants and animals (including human beings) cannot live without this element, they cannot obtain it directly from the air, for, as you have discovered, when the supply of nitrogen in the soil is low it has to be restored chemically or by the laws of nature. Plants such as beans, peas, clovers, etc., have the peculiar effect of supplying nitrogen to the soil. This is brought about by the action of bacteria in the roots, which convert the nitrogen in the air into a form which is available to all plants. This is one of Nature's ways of balancing the supply of plant food.

To preserve the plant food in the soil, exhaustive crops should be followed by restorative crops. This, of course, is not always possible, and in many districts it is seldom economical, so the farmer corrects the plant food deficiency by the use of the required type of artificial fertiliser.

WATER IN THE SOIL.

[Paper read by Mr. E. Yeates at a meeting of the Hartley Branch on 3rd June.]

Water is so necessary to promote growth that its presence in the soil is worthy of our consideration. It exists in three forms. Hygroscopic moisture is a minute film surrounding all soil particles. It is of no use to plants, but is always present however dry the soil may appear to be.

The second form—capillary water—is the one and only source from which agricultural plants draw their moisture, consequently it is most important. It consists of a film around the soil grains, and dissolves from them all the elements which a plant requires; it must be remembered that a plant only takes in dissolved nutriment. The method by which this moisture is drawn in through the roots of a plant is interesting. The root hairs are covered on the tip by a membrane, through which dissolved substances will pass. The direction of the passage depends on the strength of the solutions on opposite sides of the membrane. Usually the stronger solution exists in the plant and this stronger solution draws the weaker to it. If salt is added heavily to the soil, the outside solution is strengthened until the plant solution is the weaker, consequently moisture is drawn from it, causing the plant to wilt and die. This explains why salt can be used as an effective weed killer.

Gravitational water is the excess of capillary moisture in the soil, and lodges in the space between the soil particles. It is present in water-logged areas, for in well drained soils it quickly gravitates downwards. Water-logging of ground for any length of time soon causes most plants to yellow off and die because air is prevented from reaching the roots.

As capillary moisture is so necessary, and gravitational water so detrimental for growth, there must be a condition when the correct amount of water is present. This ideal is realised when the soil is thoroughly wet and yet will not exude drops of water when squeezed together by the hands. To bring about this optimum water content drainage is essential, and in districts of heavy rainfall and heavy soils man-made drains are often necessary.

Nature's method of supplying soil moisture is by one way—rain, but it is lost in many ways. Drainage, both from the surface and underground, accounts for a large amount of loss, but evaporation is the most important, because it robs the ground of moisture that could be used by plants. Capillary moisture is always rising to the surface and is consequently always being evaporated to some extent. To reduce this to a minimum cultivation has become a standard practice, because by the preparation of a mulch the capillary tubes are broken. Australia's dry climate has made necessary some kind of water conservation, and it is fallowing that has made possible the heavy yields of to-day, more so perhaps than super. It has been estimated that as much as 5in. of rain is conserved in one fallowing period.

Water is also taken from the ground by the growth of plants. A small amount of this is used by the plant itself in building up its body tissue. A young wheat crop is approximately 68 per cent. moisture, and green lucerne 73 per cent., but this is relatively small compared with the amount transpired by a plant. The amount of transpiration is considerable, *e.g.*, a large sunflower will exhale as much as a pint of water during a summer day. Lucerne transpires much more quickly than other green crops, 800lbs. being lost per acre, but only 230lbs. on the same area of wheat, consequently lucerne demands a tremendous amount of water to grow prolifically. Plant leaves are so adapted that the pores close as the leaf wilts, stopping to some extent the amount evaporated through the plant. After all these sources of moisture loss have done their worst, is it any wonder that there is very little moisture left after summer?

MANAGEMENT OF A MIXED FARM.

At a meeting of the Truro Branch of the Agricultural Bureau held on 18th May, Mr. E. W. Berry read a paper entitled, "What I have learned from Experience in the Management of a Mixed Farm." In the course of the paper Mr. Berry stated that during 22 years as a member of the Agricultural Bureau he had found that mixed farming was a most interesting occupation, provided the farmer was situated in a district of 15 to 20in. rainfall, and could get a payable price for his products. The most profitable method of marketing oats and barley was to turn them into lamb or pork, preferably lamb. A suitable plant to work a 600 acre farm would consist of an 8-horse team with 1 spare horse, a 5-furrow plough, 8 harrows, a 16-hoe combine, and an 8ft. harvester in preference to a header. The harvester could be worked with only 6 horses, thus providing 2 spare horses, which should, if possible be mares with foals. The team should always be kept up to a good standard. At seeding time a good team would sow 17 to 20 acres a day, whereas a slow team would only cover 12 to 14. Working the land for wheat growing depended largely on how the farm was subdivided. A large paddock should be worked on a 3-year rotation, sowing, say, 50 to 60 acres to oats and barley. It was better to sow, say, 7½ bags per acre twice in 6 years, rather than to grow 3 crops out of 5 bags in the same period. The former pratice encouraged the growth of clovers which greatly improved the land. Fallowing should be started in July, ploughing fairly wet and not more deeply than 3in. Harrowing and cultivating should be done as weeds made it necessary, but it was not wise to cultivate deeply before seeding. For the Truro district late seeding was preferable, say from the middle of May to the end of June, sowing late or mid-season wheat. It was a good plan to have about 20 bags of early varieties of wheat on hand, for use in case the season opened exceptionally late. Seeding should be at the rate of 60 to 75lbs. of graded seed per acre—that amount being the equivalent of 10 to 12lbs. more of ungraded seed—with from 100 to 150lbs. of 45 per cent. super, the more the better.

Livestock.—It was not advisable to run sheep in with big stock. If sheep had the run of the farm they would eat all paddocks bare, with the result that if the first rains came rather late, there was no dry cover for the young feed; and consequently feed would be scarce until August and sometimes later. When sowing oats or barley in a paddock which was to be left out for a year or two, it was a good plan to sow some Wimmera Rye grass mixed with super. It made excellent feed, even when it was dry on the stubble. Where a good dressing of super was applied to the land, stock received a certain amount of it through the feed.

Superphosphate was very important. No farmer would think of sowing a crop without super, yet if he could put on ½cwt., there was no reason why he could not apply 1½cwt. With super at £3 7s. 6d. per ton, the cost of the extra super would equal the price of 1bush. of wheat per acre, and the increased return would surely be more than that. Some farmers were in a vicious circle, in that they had cut down the super on account of the low price of wheat, resulting in a poor crop. Consequently they had less money for super the next season, and the crop went yellow, with green patches where horse or cow-manure had been, and provided no feed for stock, and the land was becoming covered with stinkwort. Had such farmers applied a good dressing to the land, they would have grown a better crop, which would have enabled them to give a heavier dressing in the following season, with a still better return, and with a much better stock carrying capacity. Points to be emphasised were the following:—1. Do not forget to attend the Bureau meetings regularly; (2) fallow early and not to deeply; (3) Do not crop more often than once in 3 years; (4) Do not try to do more than you are able to attend to properly; (5) Do not put sheep and cattle in the same paddock; (6) Do not fear to use super. It will not blight the wheat, and 1cwt. costs only the price of 1bush. of wheat. Five years ago it cost as much as 3bush.; (7) Use graded seed wheat if possible, and give the small grain to the fowls.

LUCINDALE SIXTH ANNUAL PASTURE COMPETITION, 1935.

[*Judges*: E. S. ALCOCK (District Agricultural Instructor) and G. W. LANGBERG.]

In the pasture competitions conducted by the Lucindale Agricultural Bureau in 1935, three entries were received for sown pastures and the Virgin Scrub Competition attracted eight entries.

Entries for each year are shown below:—

Year.	Natural Pasture.	Sown Pasture.	Virgin Scrub.	Total.
1930	8	12	—	20
1931	5	12	—	17
1932	5	10	—	15
1933	7	13	—	20
1934	—	3	—	3
1935	—	4	8	12

The Cup for Natural Pastures has been won outright, and this class was replaced with the Virgin Scrub Competition.

Trees, broom bush, and heath in 1934 before work was commenced (S. F. Grieve).

It is necessary in this district to top-dress early because it is impossible to drive a heavy loaded vehicle over the paddocks during winter. The heavy rains came earlier than usual, and many landholders were caught with this work not completed, and because of the boggy nature of the land, it had to be left. It was easy to see the paddocks and portions of paddocks dressed with super. Even the land which was fairly wet and even under water during the winter months showed quite a good deal of improvement after top-dressing.

The pasture as it appeared in Autumn, 1936 (S. F. Grieve).

To get the best out of pastures, they need to be sown just as carefully as a cereal crop and should be given the same care and attention but generally, this is not done. The general opinion seems to be that it is only a pasture and it does not appear to matter when or how it is fed or treated.

Most pastures are allowed to grow too rank at certain times. If they cannot be kept down by grazing, they should be shut up and cut either for ensilage or grass-hay, and the stock crowded on to a smaller area in order to keep the pastures in good condition.

Shade is an important item, especially during summer and winter. One very valuable tree which grows well in this district is the Dry Land Titree—it is a good shade, does not grow high, and there is no danger of limbs breaking, as is the case with some of the gums.

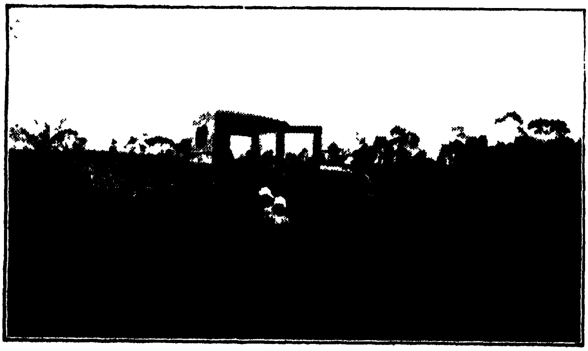
SOWN PASTURE COMPETITION, 1935.

The points awarded under the various headings are given below:—

Competitor.	Address.	Position.	Bulk of Pasture per Acre.	Type of Plants.	Freedom from useless Plants.	Feeding Value.	General Care.	Area.	Total.
			30	15	25	10	10	10	100
R. J. Legoe	Callendale	1	26	14	23	9	8	10	**90**
R. G. Nosworthy	Lucindale	2	24	13	22	8	7	10	**84**
A. T. Williams	Conmurra	3	23	12	22	8	7	10	**82**
W. O. Smith	Lucindale	4	20	10	20	7	6	10	**73**

COMMENTS ON WINNING CROP.

R. J. LEGOE.—"Callendale" Lucindale 64 acres. A very fine paddock, sown with Rye Grass, Subterranean Clover, and White Clover. Portion of larger paddock, and was fenced off early in the year. A very nice pasture, quite a good mixture and had been well grazed, as the following figures below indicate. There was a little Silver Grass and Slender Clover. Topdressed with 1 bag super per acre. Grazing is given as follows:—



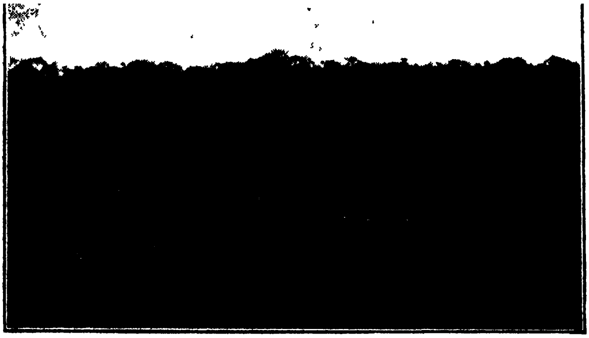
Rye grass, oats, and clover, 1935 (S. F. Grieve).

1935.			
March 16–20	4 days	600 sheep	2,400 sheep days
March 25–28	3 days	289 sheep	867 sheep days
April 5–17	12 days	41 sheep	492 sheep days
April 17–26	9 days	250 sheep	2,322 sheep days
April 26–May 13	17 days	251 sheep	4,267 sheep days
May 14–August 13	91 days	364 sheep	33,124 sheep days
August 15–September 25	41 days	296 sheep	12,136 sheep days
September 25–26	1 day	784 sheep	784 sheep days
September 28–October 8	9 days	150 sheep	1,350 sheep days
October 8–29	21 days	778 sheep	16,338 sheep days
November 1–4	3 days	299 sheep	897 sheep days
November 7–14	7 days	334 sheep	2,338 sheep days
	218 days		77,315 sheep days

$$\frac{77315}{365 \times 64} \doteq 3.309 \text{ sheep per acre per year}$$

VIRGIN SCRUB TO PASTURE COMPETITION.

The object of this Competition was to ascertain the best method to establish a pasture from virgin Scrub and at the same time it was hoped that all Competitors would keep a record of the labour involved on this work so that the actual cost could be ascertained. Each competitor was requested to keep a record of the number of days work on their entry, the number of men, the number of horses and implements used and, where contracts were let, to give the cost of same per acre. The Competition will be conducted for 5 years with an annual prize each year, and a champion prize at the end of the fifth year (1939).



The pasture in 1934, showing yaccas and heath in foreground (S. F. Grieve).

This Competition will show the various methods employed by different individuals in establishing pastures. Some have fallowed their land and left it bare for 12 months; others have rung and poisoned the gums and then cut them down and sold the wood for burning; others have pulled them down and burnt them in heaps. Some have sown cereals and others a summer crop. Another competitor sowed Subterranean Clover and expected it to make enough growth to get a burn to destroy the gum shoots. Another competitor put an Oat crop with the Clover and grasses in the first year. Nobody attempted to use Wimmera Rye Grass for the first crop; the grass grows readily and should carry a fire well.

Broom bush and heath on left and rye grass and clover on right, 1935 (S. F. Grieve).

All the entries were inspected before work began, and in order to put all on an even footing, they were handicapped according to the type of soil and the vegetation growing on them. They were classified and handicapped as follows:—

Stringy-bark scrub	100 points
Hill, Red, or Blue Gum and Yacca scrub ..	75 points
Heath and Yacca	40 points
Heath	30 points

The lightest and poorest type of soil with the most difficult clearing was given the highest points of advantage. Entrance fee, 10s., for each entry, and this amount to cover the period of 5 years. Area not to be less than 20 acres. This year 8 entries were received, and as these covered quite a number of different types of soil and vegetation, some interesting information should be obtained.

Some difficulty was experienced in arriving at a satisfactory scale of points to judge the entries. However, it was decided that as this was a pasture competition, all entries would be judged at the same time and from a grazing standard, even if they were eventually cut for hay or harvested for seed.

Commencing clearing, 1934 (T. W. Ferguson).

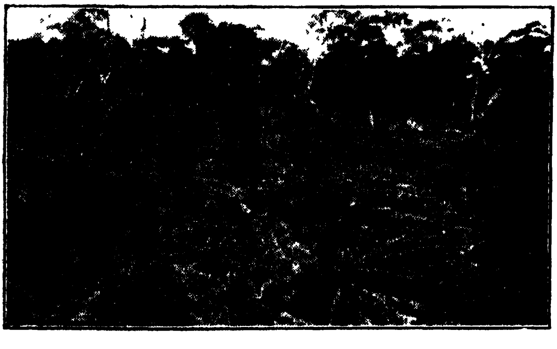
Land and Vegetation.—It was agreed to allow the maximum 100 points handicap for entries whose natural vegetation consisted of Stringy-bark and Bracken Fern Land; Red Gum, Hill Gum, Yacca, etc., 75 points; Heath and Yacca, 40 points; Heath only, 30 points.

Germination and Growth (50).—Considerable skill is required to grow a good crop on virgin land, and, therefore, "Germination and Growth" was given 50 points.

Records (30).—The value of complete records is invaluable in such a Competition as this, and therefore, 30 points were awarded.

Fencing and Water (50).—The areas must be fenced off securely to protect them from vermin so that they can be fed off properly. Good clean water is essential for grazing animals.

Crops Used (50).—This is important, because there is not one of the areas entered on which some crop cannot be grown.



Yaccas grubbed and before burning, 1934 (T. W. Ferguson).

Feeding Value of the Plants Sown.

Management (50).—Success depends on good management, and 50 points were allotted for work done carefully and on economical lines.

DETAILS OF POINTS AWARDED.

Name.	Disposal of Land.	Land and Natural Vegetation.	Germination and Growth	Records.	Fencing and Watering.	Type of Plants Sown.	Feeding Value.	Management.	Total.
			50	20	50	30	30	50	300
S. F. Grieve—Oats and grasses		74	40	19	5	80	30	15	214
S. F. Grieve—Clovers ..		75	40	19	5	30	30	15	214
T. W. Ferguson—Rape ..		60	30	15	40	20	25	10	200
T. W. Ferguson—Wheat		60	25	15	40	15	20	12	187
W. O. Smith—Subterranean Clover		70	25	18	20	15	20	8	176
R. J. Legoe—Part ploughed		40	—	—	—	—	—	—	40
R. G. Nosworthy—Ploughed		35	—	—	—	—	—	10	45
W. M. Secker—Not started		80	—	—	—	—	—	—	80

S. F. Grieve, "Karana," Lucindale, 40 acres (2 entries).—Rather light soil carrying small Yacca and a few scattered Hill Gums. Recently burnt when inspected in 1934, also a few patches of Broom Bush and black Grass. This area was ploughed with a disc plough, 5-furrow, and ploughing was started on 16th November, 1934, and completed first week in February, 1935. Where the fire went across this plot, the land ploughed and went down better than the unburnt portion. This was cross-ploughed the first week in March and completed in second week in April. This second working made a splendid job, and it was then harrowed, which took three days to complete. This was then sown with 60lbs. Algerian Oats, 40lbs. super, with the following seeds:—2½lbs. McDougall Wimmera Rye Grass, 3lbs. Subterranean Clover, and 1lb. of the following mixture per acre:—25lbs. Kentucky Blue Grass, 20lbs. Brown Top, 20lbs. Red Clover, 50lbs. Bokhara Clover, 10 *Phalaris Tuberosa.* All seeds were mixed with the super which were sown through a top-dresser with 90lbs. super per acre, followed behind the combine. Seeding started on 2nd May and was completed

May, 1935, after yaccas were burnt (T. W. Ferguson).

Dry trees after poisoning, and burnt yaccas, May, 1935 (T. W. Ferguson).

23rd May. Total area on this black, 115 acres. Cost per acre, £1 14s. 7½d. Grazed with 200 sheep which were put in on 16th September.

Details of Expenses for 115 *Acres.*

	£	s.	d.	£	s.	d.
Wages—Cleaning saplings, 14 days at 10s. per day	7	0	0			
Ploughing	25	0	0			
Harrowing	3	10	0			
Sowing	9	10	0			
				45	0	0
Fuel—484 gallons kerosene	27	4	6			
Oil	3	2	0			
10 gallons petrol	0	17	6			
				31	4	0
Seed—Clover, Wimmera Rye Grass, etc.	52	15	0			
Oats	12	0	0			
				64	15	0
Super—7 tons at £3 13s. 6d.				25	14	6
Depreciation (value of plant approximately £320)				30	0	0
Breakages				2	8	6
Total				£199	2	0

Cost per acre, £1 14s. 7½d.

The Oats made quite good growth, and the Wimmera Rye Grass and Subterranean Clover germinated well and also made good growth; some Brown Top and Bokhara Clover and Red Clover, but very little of the other plants were to be seen, and this area looked quite promising. Mr. Grieve said he would remove the sheep at the end of October to give the plants a chance to re-seed themselves.

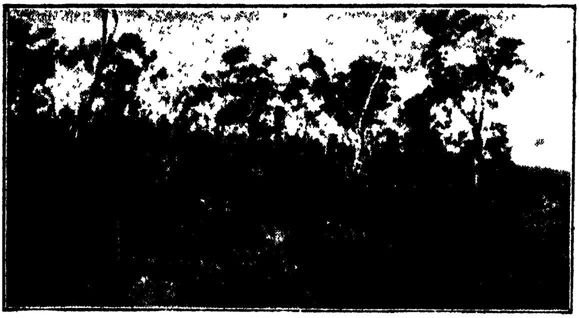
Large dry trees, May, 1935 (T. W. Ferguson).

T. W. Ferguson (2), Baker's Range, Lucindale.—Similar to the other entry by the same competitor, but was given different treatment in clearing timber and also first crop. The Yaccas were grubbed off and the timber ring-barked and poisoned. The timber was pulled down with a tractor and dragged into heads on the head-lands. A good deal has yet to be dealt with. Cost per acre, £3 14s. 2d.

Clearing is not by any means completed. Rape had germinated well and looked very promising, and this should make quite a good seed for a pasture crop.

T. W. Ferguson (1), Baker's Range, Lucindale, 20 acres.—Fairly fertile loam; vegetation mainly fairly large Yaccas, rather thick with a good many trees, as shown in the photo. The Yaccas were grubbed out by hand, and the timber burnt after it had been ring-barked and poisoned. The logs were dragged into heaps and the loose stone carted off. Ploughed with a tractor and sown with 1¼bush. of Major wheat and 1cwt. super per acre. Cost per acre, £4 6s. 8d.

This area is not properly cleared. The wheat crop was only fair; rather thin and did not look very robust.



Before clearing was commenced, 1934 (W. O. Smith).

W. O. Smith, Lucindale, 30 acres.—A fairly level block; the soil a fertile loam which, with the addition of phosphates should grow a good pasture. Scrub consisted of Yaccas, Hill Gum, Blue Gum, small Honey Suckle, and some grass in the open places. The timber had been poisoned and ring-barked. This work was done partly by day work. Mr. Smith considers the cost (10s. per acre) rather high, despite the fact it was rather heavily timbered—this was done in 1927. Falling and burning of dead timber cost 5s. per acre. This was let by contract after a much lighter timber had been removed gratis by people requiring firewood. This

The land in 1935 (W. O. Smith).

Part ploughed, October, 1935 (R. J. Legoe).

was done December, 1933, to February, 1934. All the stumps were cut off level with the surface. Ploughed with twin disc during June and July, 1935, and then cross-ploughed. 6lbs. Subterranean Clover seed per acre and 1 bag 45 per cent. super per acre. These costs were approximately

Before ploughing, 1934 (R. G. Nosworthy).

£2 per acre. Mr. Smith hoped the Clover would make sufficient growth to carry a fire to check growth of shoots, etc. Rather rough with some gum boughs, dry Yaccas, little Silver Grass, and few thistles; Clover sown too late to make good growth. Nevertheless, a good foundation for a pasture.

Ploughed land, October, 1935 (R. G. Nosworthy).

R. J. Legoe, Callendale, Lucindale, 20 acres.—A good heavy type of **fertile loam. Mainly fair-sized Yacca with some Hill and** Blue Gums.

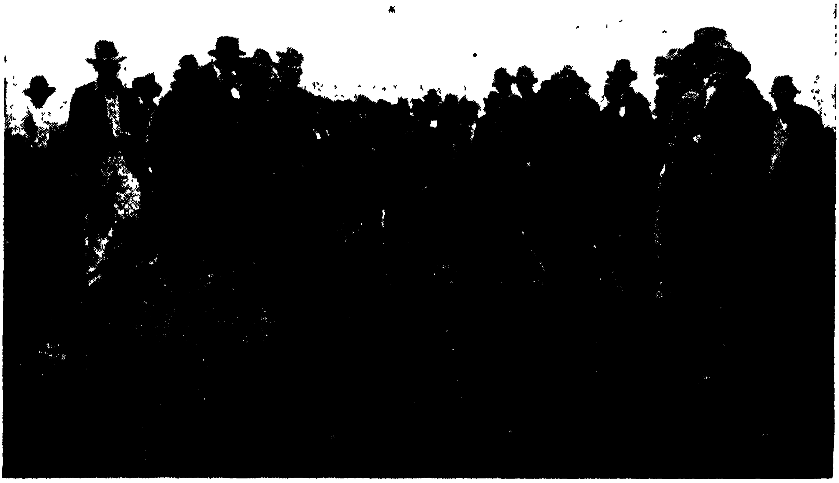
Before clearing, 1935 (W. M. Secker).

Very little has been done to this area. Last spring a start was made **with ploughing, but owing to a breakdown, this had been left.**

R. G. Nosworthy, Lucindale, 20 acres.—A very fertile loam with a good deal of organic matter in it. This area should grow an excellent pasture. Mainly Yacca with very occasional Honey Suckles and Sheoaks; also a few White Gums. Ploughed and left in the rough. No great difficulty was experienced in the clearing of this area.

Another view before clearing, 1935 (W. M. Secker).

W. M. Secker, Ardune, Lucindale, 20 acres.—Rather light and sandy, but should carry a good pasture. Mainly Bracken Fern, odd Manna Gum, and Stringy-bark. No work was done to this area up to December, which will be the most difficult to clear effectively.



A Pruning Demonstration given by one of the judges at the Annual Pruning Competition at McLaren Flat on 30th May, 1936.

SUMMARY OF REPORTS RECEIVED.

WOMEN'S BRANCHES.

DRESSMAKING AND THE ART OF DRESS.

The following paper on "Dressmaking" was read at a meeting of the Monarto South Branch by Mrs. E. A. Thomas:—The first move in constructing a gown from a pattern of stock proportions is to place the pattern against the figure to assure a fit. To test the sleeve, pin the pattern together, and gently fit to the arm.

Method.—(1) Place pattern to figure. (2) Press out crease in material and paper pattern. (3) Lay pattern as shown in diagram, folding material, selvedge to selvedge where directed, reading instructions on pattern and carefully noting "place to cross of material." (4) Mark all notches and guides to pleats, facings, and folds, and mark centre-backs and centre-fronts with coloured thread. Cut out and tack carefully.

When the garment is ready for sewing prepare the machine for use. Clean and oil first and, placing a piece of cloth between the presser foot and teeth, work the machine for a few seconds to let the oil get well into the bearings. Wipe off any oil with a cloth. A needle with a blunt point can be sharpened on an emery kept for the purpose.

Commence by stitching along the shoulders, then the side seams and the sleeves. Cut away any untidy edges of the seams, and make them neat by overcasting or turning under the edge once as a fold and stitching. Press these seams before doing anything further. To get the best results seams should be pressed before and after making neat. Press on the wrong side. Open out the seam, and place a damp cloth over it and press from the top downwards.

Making the Collar.—Place the two right sides together, tack, and stitch around the edge. Cut off corners of any points diagonally so that it will not be thick when turned out. Turn collar, keeping seam exactly along edge of fold, and press. Do not attempt to press without having first tacked around. A little extra trouble in the first stages will give better results, and may save a lot of worry later on. Mark position on neck of frock where the opening of collar is to be, whether in centre-front or at the side. Then mark centre-back of collar and centre-back of neck on frock. Pin collar to frock with these points meeting. Cut a strip of lining on cross about ¾in. wide, and tack around the right side of lining facing right side of frock, tacking through all thicknesses. Machine these together ¼in. from edge, cut away the edge, and turn facing over so that not any will be seen from right side and, turning in the raw edge, hem around to frock invisibly.

Putting in Sleeves.—Pin sleeve seam in position; turn garment to wrong side, leaving sleeve inside, and hold towards you with edge of sleeve even with edge of armhole. The sleeve which is the fuller is held on the top over the hand, and eased into size of armhole. Tack together before machining. Sleeve seams can be bound with a strip of thin material cut on the cross to make the edges neat. The cuff end can be finished off before the sleeve is put in if desired. Sleeve and collar may be left tacked until after the second fitting. Now place frock on for fitting, pull into place, and pin belt in position. Look over it very carefully, and note if any correction is necessary.

Measuring the Length.—Take up the length by marking an even distance from the floor. Use a yard stick and chalk, mark the length you want from the floor on the ruler. Move this around, and place a pin at intervals all the way around the skirt. If it is necessary to take your own length use the yard stick, and standing still and erect move the ruler around, putting a chalk mark on skirt at the height. This should be done in front of a mirror. Remove frock from figure, and cut away an even width from the row of pins. Turn up at the length marked, and tack along the fold at bottom. Turn in a fold at edge of hem, tack and slip-stitch by hand, and press. In thick material it is best not to turn in the edge, but stitch a piece of bias binding along. This can then be tacked flat and stitched. Ease any fulness that is likely to occur rather than put in small pleats, and do not machine the hem if the frock is to have a well-made appearance.

THE ART OF DRESS.

Under this title the following paper was read by Miss K. M. Hutchesson, of the Millicent Branch:—Clothes, it is said, make the man, but equally they can, and often do, mar the woman—a fact that too many women sometimes fail to realise. Dress is one of the most important aids to beauty. The woman who studies her type and modifies fashions to suit it is the woman who always looks well dressed. First think of a good foundation garment, and when this has been achieved the next problem is choosing of styles that are most becoming to a particular type of figure such as:—

Wide Shoulders.—For this never have wide reveres on dress or coat or any other form of width-giving trimming.

Narrow Shoulders.—Concentrate on widening the shoulders as much as possible, such as wide circular collars that come well over tops of arms. Swagger coats with wide raglan sleeves or three-quarter width wide reveres.

Broad Hips.—Women whose hips are broad should have skirts cut on the cross with insets placed flatly down centre-back and centre-front of skirt. Never have a sash end tie so that it falls on hips. If the hips are broad never let the skirt be brighter in colour than the top of frock. Tailored dresses should be chosen instead of blouses and skirts.

Arms.—If your arms are large never wear a sleeveless frock, but have your trimming below the elbow so as to make the top of arm look slender.

The Bust.—A cross-over line to the bodice gives a slender look to the too-full figure. A frilled jabot, pleated insets in the bodice, or a long cowl front are a few suggestions to the too-slender figure. Figured materials can be worn to an advantage, and square and round neck openings should be chosen instead of V-shape.

Collars.—The question of collars in relation to the type of neck is well worth studying. If the neck is short do not give the dress a collar that conceals what little you do possess! Avoid frills around the neck. Choose, instead, a turn-down collar with a V-shaped opening, or, if the style of the frock makes a square or round neck essential, be sure that it is cut low so that as much length as possible is given to the neck. For a long thin neck V-shapes must be avoided. Rounded and rather high-cut neck lines are best.

Jewellery.—A necklace is a help in disguising neck length. Luckily there is no lack of variety in modern jewellery, and these can be easily found to suit your requirements.

Footwear is another important part in the art of dress. If the ankles are large do not choose a short-toed shoe, but one that has a fairly long toe and moderately high heel. High-heeled, short-fronted shoes must be left to the woman who possesses a small plump foot and slim ankles. Self-colour shoes should be worn by the woman with large feet. It is best whenever possible to wear shoes of the same colour as the dress or suit. This is not only good from a fashion point of view, but is becoming to both large and small feet. In the case of the former matching shoes will make the feet less noticeable, and will make small feet appear still more dainty.

Hosiery is another fashion point that needs to be considered. Very bright flesh shades should be avoided by the woman with fat legs—a deeper shade is better. Always take the trouble to see if the back seam is straight, or a clumsy ungroomed appearance will result. Few women realise that a well-fitting stocking is as important as a well-fitting shoe.

Lingerie.—Well-fitting lingerie is an important asset to a neat figure. It is better to chose garments that have lace motifs inset rather than those trimmed with lace frills or frills of materials which might give a bulky effect when worn under close-fitting clothes.

Initials in metal are also one of fashion's favourites for ornaments, but these should be used with discretion. No one type of ornament should be over done.

Colour plays an important part in women's dress. The choice of the right shade to suit the complexion, the selection of good combinations of colour, and the achievement of the right colour to suit her surroundings are all points the artistic woman has to consider to secure beauty in dress. It is surprising how many women quite happily wear a green hat with a brown coat, a blue scarf with a dress beneath probably of a different shade from any of these. This unhappy collision of colours is due to the fact that the woman buys her clothes thoughtlessly. If the dress allowance is limited do not buy a thing because you fancy it, but consider in the first place whether you have any garment with which it can be worn. The danger of colour clashing lies not so much in the alliance of two contrasting shades as in two shades of the one colour or one to which it is closely related.

In dealing with colour in fashions one must consider design in dress materials. Careful choice is needed in selecting the design. The short, plump woman, for instance, should not wear a fabric that has a dark background with large bright floral design. A large woman can wear a big design as long as it is not too closely printed. The thin woman should choose a check, scroll, or a floral design. The small woman should choose a design that is closely printed. She can wear a spot design and dainty floral patterns.

Gloves are another fashion detail that must not be overlooked in achieving a well-groomed appearance. Choosing clothes or trimmings in the right light is an important factor in successful shopping. The woman who always looks well dressed is the one who chooses the right clothes for every occasion.

The shop worker often has her problem solved for her as she usually has to conform to regulation style. The office worker should avoid any kind of trimmings that may catch in office furniture, or sleeves so wide that they will become entangled in her typewriter or sweep her employer's papers off his desk when he is dictating letters. It is never necessary to look dowdy. The business girl can be as smart as her sister who does not work for her living. When a girl is facing an interview with a prospective employer she must take special care to wear the right clothes. She should dress quietly, and aim to look smart and businesslike. No dress is too elaborate for fashionable race meetings and garden parties, but care must be taken that it is not too elaborate for the wearer.

There are some lucky women who appear to have the gift of eternal youth. When they are in their late thirties they still look 25. Such women need have no compunction in dressing youthfully. Another type to be considered is the elderly woman—say, in her fifties and early sixties. Elegance must be the aim of the elderly woman; she must never make herself conspicuous by wearing bright colours or by adopting extremes of fashion. There is no need for her to be dowdy. She needs well-cut clothes that are dignified, and must not try to disguise her age.

The woman who may be described as a "busy housewife" is in a different category from those already dealt with. Possibly she lives in the country, and has very little domestic help, and can only pay occasional visits to town to buy new clothes. In other circumstances she might live up to her type, be it exotic, fragile, or artistic, and dress accordingly. When, however, she has a hungry man to cook for, maybe several children at her heels, and possibly work to do in the garden or the various details in connection with a farm house to attend to, this is not possible. She cannot wear clothes chosen by her town-dwelling sister, but she can take an interest in her appearance all the same. A woman that knows that she has made herself look as nice as circumstances permit feels a satisfaction that is definitely helpful.

It is a fatal mistake to lose interest in dress. There are women who will not trouble about their appearance because they do not enter into any great social activity. This is a selfish outlook. They should at least try to be pleasing to the eye for the sake of the people they live with, whether these be husband and children, parents, or brothers and sisters. For all occasions dress must be worn with order and dignity carefully kept and carefully put on.

COMPETITION AT GLADSTONE.

The Annual Competitive Exhibition of Women's Handicrafts was held on 19th May, there being an attendance of 33 members and 30 visitors. Mesdames Lyons, Smallacombe, Nancarrow, and McDonald, of the Georgetown Branch acted as judges, and made the following awards:—Knitted garment—1st, Miss J. Ballantyne; 2nd, Mrs. R. Lines. Babies' outfit, three-piece—1st, Miss Hewett; 2nd, Mrs. W. Ballantyne. Knitted sock—1st, Mrs. Appleton; 2nd, Mrs. G. Smallacombe. Crotchet d'oyley—Miss Jean Ballantyne, 1st and 2nd. Most useful article, value 1s., 1st, Mrs. M. Read; 2nd, Mrs. E. Pearce. Fancy work—1st, Mrs. R. Lines; 2nd, Miss Milligan. Plain sewing (apron), 1st, Mrs. H. Bennett; 2nd, Mrs. R. Lines. Scones—1st, Mrs. W. Ballantyne; 2nd, Mrs. M. Read. Butter sponge—1st and 2nd, Mrs. Barrett. Tarts—1st, Mrs. F. Weinert, 2nd, Mrs. R. Lines. Biscuits, 6 kinds—1st, Mrs. G. Smallacombe; 2nd, Mrs. Ballantyne. Sausage rolls—1st, Mrs. Weinert; 2nd, Mrs. G. Smallacombe. Polished shoe—1st, Mrs. Sambell; 2nd, Mrs. Prior. Prizes were presented by Mrs. Lyons. Mrs. Spotswood proposed a vote of thanks to the judges, and her remarks were indorsed by Mrs. R. Lines.

HOUSEHOLD HINTS FROM MONARTO SOUTH.

Mrs. H. B. White presided over an attendance of 12 members and 4 visitors at the meeting held on 16th May. The following useful Household Hints were given:—(*Miss E. Hein*) When making fruit salad, soak the oranges first in boiling water, letting stand for 5 minutes. The white, pithy part will come off quite easily with the skin and the orange is left clean for slicing. Milk can be kept fresh in a bottle of red glass. Pure, sweet milk in a plain glass bottle is utterly spoiled if left one day in sunlight, but unsterilised milk in a red bottle, or even a bottle wrapped in red paper, keeps good in the sun. (*Miss O. Baum*) When washing crepe-de-chene garments, always add a little methylated spirits to the rinsing water (1 tablespoonful to a gallon of water), wring and roll in a towel and leave at least 4 hours before ironing. This method keeps them like new until they are worn out. Cucumbers that are soft and limp need not be thrown away; simply roll them in wet tissue paper, this will make the limpest cucumber hard and keep it so for days. (*Mrs. Dohnt*) In hot weather it is a good plan to rub over a joint of meat with vinegar as soon as it is received. This will keep it fresh. Mixed with tea leaves, vinegar shaken in glass bottles keeps them clean. One part of vinegar and two parts of linseed oil is an excellent preparation for cleaning leather articles and furniture. Soak gas mantles in vinegar, and then dry them before burning off and they will last much longer. Add a teaspoonful of vinegar to the water when poaching eggs; the white will not spread. (*Mrs. G. Strauss*) On a damp washing day, add a good handful of starch to the blue water; it helps the large articles to dry quicker. To cool an oven, place in it a basin of cold water; this will quickly reduce the temperature. To remove tea or coffee stains—immediately after the linen has been stained hold it over a basin and pour boiling water through it. The stains will at once disappear. (*Miss S. Schenscher*) When making a cake with dripping add the juice of a lemon to each pound of dripping; this will be equal to butter. The best way to clean a white enamel bath is to put a little turpentine in a saucer, get a small piece of rag and well rub the bath all over with the turps, then scrub the bath with soap and warm water. (*Mrs. C. F. Altmann*) Before pressing a coat collar or reveres on a home-made coat, soap the two pieces of material on the wrong side and the heat of the iron will make them stick together without wrinkling. To prevent milk from burning—before putting milk in the saucepan, boil rapidly a few tablespoonsful of water, just enough to cover the bottom of saucepan, and it will never burn however fierce the fire. (*Miss F. Aesche*) After pig runners are washed in several waters, soak them in clean water in which a little alum has been dissolved, it will take off all the slime.

LUNCHES.

Paper read by Mrs. E. Doig at a recent meeting of the Devlin's Pound Branch:—In cutting sandwiches, put green leaves around them, and then the cloth helps to keep them fresh. Never put meat in between bread and butter; cut slices of meat, and wrap in grease-proof paper. In sending lunches out, always keep a small jar of pickles to add to the sandwiches. Tomatoes, onions, and eggs: Do not cut any of these up and add to the sandwiches, as the bread and butter gets very unpalatable. Brown bread is best; it keeps fresh longer. Small cakes are preferable. The main thing is to change the lunches as much as possible. A little fruit salad can be put in a small glass jar, or a small fruit pie. If tea is sent out to the paddock "dry tea" is best. Tea that stands in a tin develops a very nasty taste; if made fresh, it is much nicer. Use lemon in place of sugar. To keep lunches nice and cool, put all in a box, wring a bag in salt and water to which a little blue has been added, wring fairly dry, place the box inside, then take a dry one and wrap around it, and, if kept in the shade, the food will keep cool and fresh.

Fillings for Sandwiches:—Mince cold roast beef, with a little fruit chutney; use white or brown bread; shredded lettuce may be added. Corned beef and sweet pickle, with brown bread. Hard boiled eggs and shrimp paste; add lemon juice; cayenne pepper to flavour. Tomato and mint.—Slices of ripe tomato, finely chopped fresh mint, pepper and salt, a few drops of vinegar.

Pie for Lunches:—1 breakfast cup of mixed meat, I dessertspoon of finely chopped onion, 1 teacup of creamed potato, seasoning, a little milk, short crust pastry. Cut the pastry into rounds about ⅛in. thick; choose fairly large patty tins, and grease them well. Mix meat, onion and seasoning together, and put into each pie a good dessertspoon of the mixture; then cover with mashed potato, brush over with milk, then bake in a fairly hot oven until crisp and brown.

Raisin Shorts.—8ozs. plain flour, 1 level teaspoon baking powder, 2ozs. sugar, 4ozs. butter, 1 egg, and 2 tablespoons cold water. Rub butter into flour and sugar, mix to a nice dough with beaten egg and water, adding a little more water if too stiff. Knead a little, then roll as near square as possible, spread one half with raisin mixture, and fold the other on top. Roll again a little, then place on cold greased tray; cut into fingers with a sharp knife; brush over with milk, and sprinkle with sugar. Prick all over with a fork; bake from 10 to 15 minutes. Nuts can be added to the mixture if liked.

INFANT WELFARE.

The following paper was read by Nurse A. Limbert at a recent meeting of the Coonalpyn Branch:—Australia is in great need of all the infant life possible, and it is our duty to see that the babies in our care are given the very best chance of health.

A very great deal can be done by the mother-to-be by taking more care of her own health: it is not a time to lead a lazy or invalid life, as motherhood is a natural state, but she should not get over tired—a short rest after the mid-day meal, lying down with the feet up on a level with the body, and at least 8 hours' sleep at night is ideal.

The hours before midnight are more valuable for sleep than those after midnight; if she goes to evening entertainments let it be once a fortnight at most. Over eating is a mistake, it overtaxes the digestive system and causes distress. A well-balanced diet should be taken which includes:—For breakfast—Some cereal with milk and sugar or with fruit, an egg, toast with butter, &c. Dinner—Fresly-cooked meat, vegetables, spinach, silver beet, lettuce, celery, carrots, and tomatoes are among the health-giving ones. Fresh fruit, cereals, wholemeal bread, butter, cheese, milk all contain the necessary vitamins. Plenty of water should be taken, and if constipation is present a suitable mixture is as follows:—½lb. each of figs, prunes, dates, raisins, ½oz. confection of senna, 2 tablespoons treacle. Mince all the fruit, melt the treacle with the senna, mix all together, keep in a screw-top jar. Dose, 1 to 3 teaspoons daily as required. Vegetables cooked with soda or cooked a long time or twice-cooked foods *do not supply vitamins*, which are very necessary to health. Vitamins are called "accessory food factors," and are practically of unknown constitution. Their absence causes various diseases. The doctor and dentist should be visited early. The teeth should be attended to if any decay is present and any old roots removed, as one cannot be in perfect health if the teeth are not sound. The clothes should be comfortable and hang from the shoulders—no tight waist bands or tight garters. Comfortable low-heeled shoes should be worn. Pleasant company and surroundings all help to make for a happy and contented babe. It is wiser not to take any severe form of recreation at this time such as golf or strenuous tennis. Walking in the fresh air is the very best of all exercises, but have a definite destination and objective, it makes the walk all the more enjoyable. Ordinary home duties are quite all right, but avoid heavy lifting or high reaching; when hanging clothes have the line only shoulder high. For early morning sickness a cup of tea and a little bread and butter taken before getting up will probably prevent the sickness.

The Babe.—The babe should have its own little bed always and *not sleep with its mother*. A dress basket makes a splendid crib for a young infant, and if not procurable a large clean box can be fitted with slat sides and ends by a handy person. Make the slats not more than 2in. to 2½in. apart, painted or enamelled it would be quite a nice crib for a long time, and could be fitted with legs to make it easier to manage.

The mattress could be of sun or oven dried chaff and renewed when necessary; a mackintosh with small old blanket to cover, and several flannelette sheets; a small cuddling blanket, and a large single-bed blanket. The pillow, if any, should be very flat and small and *not of feathers*. Place large blanket in crib with ends over sides, then the mattress, mackintosh, old blanket, sheets, and pillow. Put the blanket about 6in. to 9in. down from the head and over the foot of crib to allow for some to be turned over the foot, place the babe in crib after making a small hollow in mattress, cover with the cuddling blanket, and fold large blanket over—one side is enough if the weather is not too cold, but the two sides may be used according to the weather, Tuck the babe in firmly; it seems to give it a sense of security.

In winter a sleeping bag is a good thing to have, made of flannel (cream or grey), on similar lines to a nightdress, but longer and wider; fasten with large buttons on the shoulder, and turn up and button at the foot; this can be done by making it similar to a man's shirt. This will save the babe many a cold and the mother many a worry. Flannel gloves can also be made and tied at wrist with ribbon or tape, but make sure they are long enough to allow for the hand to open.

Place the crib on two chairs if no proper stand is used, and so that the light does not shine directly on to the infant's eyes, yet in an airy place. Baby can sleep out of doors very early in life. For his daytime sleep he can be put in the peram. and covered right over with a mosquito net (green is a good colour) to protect from flies, &c., and wheeled out of doors to a protected position. The net should be at least 2ft. from the baby's face. He will sleep less in the daytime as he gets older, and the afternoon is the best time for what is called "mothering" time, that is, a little extra attention and cuddling by his mother for an hour or so. A baby or young child should not be excited just before his evening meal and bedtime; quiet preparations and being quietly put in bed are great helps for a good sound sleep. Baby should be put to sleep in a room near his mother's after weaning—it helps to give a sense of independence

Feeding.—A baby's natural food is best and it is also his birthright; he should be fed regularly; 4-hourly is best for a normal babe, with no night feed after 10 p.m.—6 a.m., 10 a.m., 2 p.m., 6 p.m., and 10 p.m. is ideal. He should get sufficient food in 20 minutes. Artificial feeding should not be necessary as often as it is, and orange juice should be given daily to an artificially-fed infant. Boiled water must be given (warm) as babies get thirsty, and milk is a food, not a thirst quencher. Get baby's "wind up" before, during, and after feeding by holding in a sitting position or over the left shoulder and rubbing its back with upward strokes. Often a babe cries after being put down to sleep when, if it is raised and the back rubbed to get rid of wind, it will soon settle down and be sound asleep in a very short time.

Do not let a babe sleep on past its feed time; it should be wakened for feeding and changing soiled naps. Naps will not be soiled if the infant is trained properly from a few weeks old. Should sore buttocks occur wash carefully with a lather of a good superfatted soap and dry well, and rub in gently a little *castor oil.* If powder is used on baby use sparingly, and make sure there is not a thick layer left in the creases and folds of skin. When puting the babe down after feeding lay it on its right side as it is less likely to vomit its feed. If it is inclined to do so, it may be gently turned over on to the left side in an hour or less and not wakened.

If an infant wakes and cries for apparently no reason, make sure there is no discomfort about its clothes—no open pin sticking into it, not too many clothes on it, or its bedclothes too heavy and hot or its feet cold, or in any way uncomfortable. There may not be enough fresh air in the room, or the babe may have wind; if so, rub its back as explained before; or it may be thirsty. If it is a bad wind pain it may be given a tiny pinch of carb. soda in a little warm boiled water, and its back rubbed upwards.

Handle an infant with confidence: do not be afraid as it will then feel more secure. If the mother is nervy the babe may be placed on a pillow on the mother's lap at feeding time.

Signs and Symptoms of Sufficient Natural Milk being obtained by Infant at Regular Intervals: A contented infant, sleeping well, possessing warm hands and feet, also a good colour and firm muscular tone; a regular gain from 6-8ozs. per week being obtained in the first 6 months of age, and 4-6ozs. per week after 6 months of age. Regular, smooth motions being passed daily.

Signs and Symptoms of Insufficient Natural Milk being obtained by Infant: An unhappy, crying or screaming, restless infant sleeping badly, or a drowsy, placid infant possessing cold hands and feet; also a pallid colour and poor muscular tone, a failure to gain the usual amount in weight per week, or even a loss in weight; constipated or small, loose motions; often vomiting due to air swallowing.

Signs and Symptoms of Excessive Natural Milk being obtained by Infant: An unhappy, restless infant often sleeping badly; flushed face sometimes covered with rash; large increase in weight often followed by stationary periods; large stools, either constipated or frequent, loose and containing curds; often vomiting or suffering from colic.

To Give Fruit or Vegetable Juices.—With all utensils scalded the juice is squeezed into a standard measuring vessel, strained and diluted with warm boiled water. Orange juice and tomato juice are the most frequently chosen juices. To begin with, half a teaspoon diluted with 1oz. of warm water is given, and the juice increased gradually according to reaction of infant until the *strained* and diluted juice of one orange or one large ripe tomato is given daily. A good time for giving this solution is at 4 p.m. It is also a useful method of persuading the infant to take an extra amount of fluid (especially of water) between meals. The mother and babe should, whenever possible, spend as much time as possible out of doors. The mother should have adequate rest from babe—2 hours at least. If comforters or pacifiers are used there should be 3 or at least 2 boiled daily, and should be attached to child to prevent swallowing. If child swallows a pin or any foreign substance *do not give castor oil.* The unbeaten white of an egg is quite safe to give in the case of a pin being swallowed—about 1 teaspoon is enough for a very young child.

Mustard Bath.—Mustard baths are given for more than one reason, but chiefly in the case of convulsions; they may be due to the onset of disease or due to teething, system being below par, constipation (particularly during teething), improper diet, overloaded stomach. Onset of convulsions: Twitching of mouth, rolling of eyes, dusky colour, cyanosis, and rigidity. Get everything ready as quickly as possible. First, if a big child, get a spoon or peg and wrap it in a bit of cloth, raise head and turn to one side, and have the spoon or peg between teeth. Send for doctor if one near. Get kettle on and saucepans of water to heat, give enema of plain warm water as soon as mouth is attended to. Use 1 tablespoon of mustard to 1gall. of water, put mustard in a bit of old linen or a handkerchief and tie it securely, put it into a little cold water to dissolve, add to bath the temperature of which should be 100° or if no thermometer is handy at the heat of a hot bath.

Have doors and windows closed if in winter, undress child near fire if possible, leave napkin on if not soiled so that it can be lifted in with child, put a napkin over child and place in bath; if cold weather put a blanket over the bath. Keep water over child, and cover head and eyes with cold, wet cloth to prevent fumes getting in eyes. Keep adding hot water to keep at right temperature. When rigidity ceases (about 10 minutes) take child out of bath and wrap in two warm towels so that skin does not touch skin, and then a light warm blanket, put to bed with two hot bottles. If first enema does not act give another.

Let child sleep; when it wakens it may need a stimulant. Doctor may order brandy —1 teaspoon in water or more according to age. Doctor may order an aperient—milk of magnesia or paraffin. No food for 12 hours, only fluid, plain boiled water. Then start with weak milk mixture, increasing gradually to normal feeding in about 3 days.

Diet: 6 to 9 months of age; artificially-fed babe:—

6 a.m.—Milk mixture, 8ozs.

10 a.m.—Crust or well-baked bread baked dry in oven. Commence oatmeal jelly in cold weather or barley jelly in hot weather. Give 2 teaspoons, increasing to 3ozs. daily; do not add sugar or milk. Give also milk mixture, 8ozs.

11 a.m.—Orange juice with boiled water.

2 p.m.—Broth; plain shank broth strained; then add vegetables to broth and strain and flavour with Marmite. Milk mixture, 8ozs.

3 p.m.—Orange juice with boiled water.

6 p.m.—Milk mixture, 8ozs. thickened with Bower's sago, 1 teaspoon, or farinaceous food, 2 teaspoons.

10 p.m.—Milk mixture, 8ozs.

A suitable milk mixture for 6 months is as follows:—Milk, 3 parts; boiled water, 2 parts, with sugar added. For example, to make 40ozs. take 24ozs. of fresh milk, 16ozs. boiled water, cane sugar 3 tablespoons and 1½teaspoons. Boil milk (just boil), add water and sugar, and put into a well-scalded jug, stir while cooling, and cool as quickly as possible, keep covered and in a cool place. A cool safe can be made from a kerosene tin:—Cut sides out leaving the four corners top and bottom, cover with towelling, place bowl of water on top from which have 4 strips of flannel hanging down, put jug of milk inside on a brick, and stand the whole thing in a draught. A tray may be placed underneath to catch any water that drips down. A reliable measuring spoon can be obtained from your chemist; it is a combined tablespoon and teaspoon measure, and to measure sugar fill the spoon and level off with a knife.

Diet: 9-12 months:—

6 a.m.—Milk mixture, 8ozs.

10 a.m.—Well-cooked toast with butter, Marmite, or honey. Oatmeal jelly, 3ozs. Add milk mixture, 1oz., and sugar, ½ teaspoon.

2 p.m.—Shank broth or vegetable broth strained and flavoured with Marmite, or Marmite broth. Baked apple, rhubarb, or prune pulp. Commence with 2 teaspoons with steamed cereal cream or custard or steamed cornflour and milk. Jelly or junket; commence with 2 teaspoons. Milk mixture, 8ozs.

6 p.m.—Brown bread and butter with Marmite or plain jam and honey. Groats or Weeties, Granose, Maizena, bread and milk; add 2ozs. milk mixture. Give also milk mixture, 8ozs. Orange juice 11 a.m. and 3 p.m. with boiled water.

10 p.m.—Milk mixture, 8ozs. if necessary. (When child fully on diet this feeding is unnecessary.)

Diet: 12 months to 2 years:—

6 a.m.—Discontinue milk mixture; give orange juice.

8 a.m.—Toast with butter and honey. Porridge (unstrained) with 2ozs. of milk and ½ teaspoon sugar. Milk mixture (4 milk, 1 water), 8ozs.

11 a.m.—Water, boiled.

12 mid-day.—Broth same as at 9-12 months. White meat—fish, rabbit, tripe, brains, with white sauce. Vegetables:—Commence with pure vegetables and work up to vegetables, well mashed peas, beans, spinach, brussels sprouts; pass through a sieve other vegetables; mash finely. Sweets:—Same as 9-12 months; increase quantity. After 18 months a little red meat (scraped at first, then chopped), grilled chop or steak.

6 p.m.—Same as 9-12 months; increase quantities. Milk mixture, 4 milk, 1 water.

10 p.m.—Milk mixture only if child is frail.

CONFERENCE OF UPPER NORTH BRANCHES.

Women's Branches of the Agricultural Bureau in the Upper North were well represented at the Conference held at Eurelia on 15th July. The last Bureau Conference here was seven years ago. The women delegates held their meeting at the Eurelia Hotel, and the men in the local hall. Representatives were present from Port Augusta, Peterborough, Carrieton, Wilmington, Wepowie, Morchard, and Warcowie, 60 miles distant, where, of the nine members in this farthest north of all the Branches, five came to the Conference.

In his opening address, Mr. F. Coleman, of the Advisory Board of Agriculture, said that he strongly favoured the appointment of a woman representative for Women's Branches on the Agricultural Board.

When the women adjourned to the hotel for their meeting, Mrs. E. H. Hall (President of the Eurelia Women's Branch) took the chair. Mrs. E. P. Wall was Conference Secretary.

The Morchard Branch submitted for discussion the best way to preserve eggs, whether by greasing or in liquid. Several delegates spoke in favour of a grease preservative, which eliminated any coating on the eggs and the necessity for washing them, the use of wooden boxes with ventilation holes in preference to tins for these eggs, and the superior condition of the eggs even after six months.

A number of articles from farm and fireside were arranged on the stage of the hall for non-competitive exhibition. These included preserves and fancy work (Mrs. A. Avery), hooked rugs (Mesdames L. Schultz, A. E. Crossman, and M.

Huppatz, a still life oil painting (Miss E. Huppatz), artificial shrubs (Mrs. E. Wall), woodcarving (Mrs. M. Daly, Mrs. P. Cummings, and Miss F. Brown), knitted cushion and a toy dog made from a black fur coat collar (Mrs. J. Burns), economy-enamelled cannisters (Mrs. A. Ware), baby's knitted woollen set, embroidery, and Afghan rug (Miss M. Huppatz).

Practical demonstrations were a feature of the afternoon session of the Women's Branch of the Conference, Mrs. A. G. Avery, from Warcowie, demonstrated her own inexpensive method of bottling and preserving meats and fruits and vegetables with a home-made outfit of small ordinary screw-top bottles and a kerosene tin steriliser. Mrs. A. M. Crossman, of Warcowie, also gave a practical illustration with a slightly different method.

Boughs of wistaria, stems of hollyhock, sprays of roses, and bunches of violets all made from paper were passed round among the delegates to show the result from cut and twisted petals in forming individual flowers. This demonstration was given by Mrs. E. P. Wall, who made each individual specimen as she talked.

The following papers were read:—

HINTS AND QUANTITIES FOR ENTERTAINING.

[Mrs. C. Schulz, Morchard.]

When entertaining do the catering methodically. Everyone is anxious to have enough, but it is wasteful to provide too much. Use up the things with cream in first, if it can be managed, and a fruit cake and some home-made biscuits are a good standby, as if not required, they keep well.

One 2lb. sandwich loaf will cut 36 slices, making 18 rounds of sandwiches, which will cut into 72 small ones; ½lb. butter is sufficient to spread a 2lb. loaf for sandwiches; ½lb. of meat, cut thinly, will fill a 2lb. loaf; 6 eggs, boiled not too hard, shelled, and put into a basin with salt, pepper, and a piece of butter, the size of a walnut and mashed well with a fork will make a mixture that will spread easily, and be sufficient for a 2lb. loaf. Other flavourings, such as onion or curry powder, may be added.

To make coffee for 100, allowing 1½ cups each, requires 3galls. milk and 3galls. water. Bring to boil; have ½lb. coffee and ½ teaspoon salt in a fine muslin bag—an old oatmeal bag is excellent. Put it in the milk and water just before it comes to the boil, and leave for 10 minutes. This is strong enough for average taste.

Half a pound of tea is sufficient for 100 people; 3qts. milk is the usual allowance for afternoon tea for 100 people; 1lb. loaf sugar has approximately 112 pieces, and should be ample for 100. Cut a small round from the centre of a sponge sandwich, and the remainder will cut into 12 or 13 slices, making 14 in all.

One quart pudding or jelly is sufficient for 6 people as a sweet, and may be used for 12 small servings at a party; 1qt. ice cream will suffice for 18 plates. The allowance for each person is usually 2 sandwiches, 3 pieces of cake for every 2 people, 1 serve of ice cream, fruit salad, or other sweets.

Some Suggestions for Afternoon Tea.—(1) Ham sandwiches, cut with white bread. Celery and cheese sandwiches made with brown bread. Columbia cake. Queen cakes: Make half quantity plain, and then ice half pink and half white; cook the other with some currants added. Cream puffs. (2) Brain sandwiches, made with white bread. Egg and curry, made with brown bread. Fruit cake. Ginger sponge. Butterfly cream cakes: Make Queen cake mixture without currants. When cold, cut a little piece out of the top of each cake with an old sharp teaspoon. Fill the cavity with whipped, sweetened cream. Cut the little top piece in half, and arrange in the cream to form "wings," dust with icing sugar.

A cake that pleases the children, and also saves baking if time is a consideration, is made by using the two halves of a sponge sandwich separately. Set a rather stiff jelly in the cake tin, and when cake is required spread thickly with whipped cream and turn the jelly on to it. A red and yellow or a red and green one makes the party table look very bright. If a large quantity of ham sandwiches is required order a ham bone a few days beforehand. This can generally be bought for 1s. 6d., and the meat should be cut off and run through the mincer. It will yield from 1lb. to 1½lbs., and the bone can be used for pea soup if desired.

Add raisins to an every-day pudding for the children's pleasure, and for added flavour and nutrition. Baked apples stuffed with raisins and brown sugar and served with cream are unequalled for their flavour. Equal amounts of chopped raisins and nuts moistened with orange or lemon juice make a delicious sandwich filling.

WOOL CRAFT.

[Mrs. Ware, Wepowie.]

Preparatory Details in Knitting.—First, a right choice of knitting wool is of the utmost importance for obtaining the result desired. The instructions given in most patterns recommend a definite wool and ply as best for carrying out the individual pattern. Only by using that same wool and ply and closely following the directions can the knitter rely on obtaining the desired effect in the fabric and on giving comfort and satisfaction to the wearer.

To successfully use the directions with another wool requires great care, and any difference in thickness between the one substituted and that used for the original is sure to produce a corresponding difference in size in the finished garment. The difficulty is reduced to some extent by the system of working to measure. To this end, and before commencing the actual garment, work a piece of fabric about 4in. square. Place a tape measure widthways over its centre and, without stretching the fabric in any way, count the number of stitches to the inch. If the number of stitches to the inch be greater than the standard a smaller garment will be produced by working at such a tension—if less, a larger one.

The size of needles or hook is of similar importance. A person who works very loosely should use needles one or two sizes finer than the standard, while a larger size should be used by one who works more tightly. The stitches should just grip lightly on the needles, allowing them to move easily along the latter without dragging the work. Fabric loosely worked is apt to wear badly, besides stretching in the wash. Tight fabric tends to stiffen in washing.

All patterns are manufactured by this system of determining tension. A graph is made of the pattern required, be it flowers, objects, animals, or check designs, etc., and then the number of stitches in each different colour for each row is determined, and thus the pattern is made. With a little care any person could work any especially favoured design into a garment.

Wool should never be wound into a hard ball, as this takes away its nature, making it thin and poor. Wind loosely over 3 or 4 fingers, withdrawing the latter at frequent intervals to change the position of the ball and keep it symmetrical. Wool wound in this manner will retain its soft fullness. Never attempt to shrink yarn before knitting. There is great risk of loosening the dye and taking the nature out of the yarn, while the possible advantage in the case of a good wool well manufactured is practically nil.

Making Up a Garment.—A great deal depends upon the care with which this is done, the "finishing touch" adding style to the best of work. First run in all the ends securely on the wrong side of the garment. Lay each part of the garment separately on the ironing blanket, and pin down exactly to size and shape. Then carefully press with a damp cloth and hot iron. Sew up the seams neatly with the wool, placing the two edges evenly together and sewing stitch to stitch. Press all seams when joined. If carefully done, the joining will hardly show.

Washing.—Woollen garments should never be rubbed with soap, but should be gently moved about in warm water in which sufficient Lux or good plain soap has been dissolved to form a lather (in the case of white goods, especially their first washing, it is helpful to add a little ammonia). Hot water or too much soap or any soda shrinks wool and spoils colours; it also gives white a yellow tinge. Rinse in clean warm water of the same temperature by moving the garments to and fro—not up and down. Remove in a bundle without twisting, and squeeze out water either by putting through a wringer at a very loose tension or by placing in a heap in the centre of a cloth and twisting the ends of the cloth in opposite directions. Great care should be exercised in drying. It is absolutely fatal to hang up woollen garments to dry (even with a broom handle passed through the sleeves) as the weight of the water drags the fabric, and destroys the shape of the garment. Drying on a flat surface is best, especially if the article be laid on a clean cloth and placed on a surface which permits of a free circulation of air underneath. A frame made of wire netting is ideal for this purpose. To protect the correct shape in drying, fasten the garment to the cloth according to the dimensions required. On no account should woollen garments be put to soak or allowed to lie in a damp state. This induces shrinkage, and may cause the colours to run. To avoid staining artificial silk when washing a coloured garment made of rayon and wool, give it an extra rinse in water to which a little vinegar has been added (about 1 tablespoon to the gallon). This will prevent the colour running, and if well aired in drying any odour of vinegar will be lost.

HOME NURSING.

[Mrs. T. Orrock, Wepowie.]

Sickness in the home is often the cause of a great deal of fuss and worry. Some faint, others look miserable, and others rush about and get things in a muddle. If it is a simple malady it will soon be all right; if a serious one, getting muddled will not help in any way. Do not frighten the sick one; smile, even if you do not feel so inclined. Sick people often think they are going to be a trouble and a bother, and are very quick to notice if those caring for them think so, and they will feel very uncomfortable. If looking after anyone who is ill place the patient, if possible, in a room in which the sun will shine at some time during the day. If the light is too bright for the eyes a screen may be used; some dark material may be hung over a clothes line or towel horse. Put a green shade over the eyes, or the sick one may lie with his head at the foot of the bed where he may get more air and less light. Let fresh air in as well as the sun. Hang a sheet or blanket up if afraid of a draught. Let the air pass over and under the bed.

It is a mistake to make the room dark and dreary. In certain illnesses—sore eyes and diseases of the brain—a dark room is required, but never an airless one. If the case is infectious, such as scarlet fever, diphtheria, typhoid, &c., all carpets and curtains should be removed; only articles that will wash should be used. Make the room bright with a few flowers. Place the bed in a position that will enable the sick one to see something other than the walls. Have a small table beside the bed with a fan, magazine, covered glass of water, few flowers, and a bell. It is most irritating for a patient to want something in a hurry and have no means of attracting attention, and great harm is sometimes done. Keep the room very clean and fresh; especial care should be taken with all sanitary equipment. Do not talk about the sickness before the patient or whisper about it just outside the door. Have a table outside the room to place things upon. Only give as much food as will be eaten up at once. Never leave any food in the room. Serve all food as daintily as possible.

Make the patient as happy and comfortable as circumstances will allow. Wash all over once or twice during the day, and if restless or feverish sponge hands and face frequently. Plenty of linen in the form of sheets and pillow slips are a luxury, but one can manage with a very few. Change sheets and pillow slips every day; rinse them through water and hang out in the sun and wind to dry, or just put out in sun to air. Never mind about the ironing; they will be quite fresh again. If the case is one of infection the linen must be boiled. Old table cloths make nice tray covers or soft handkerchiefs. If old linen is scarce, and sometimes it is so in many homes, make tray and table covers out of clean newspaper, also serviettes, then these can be burnt, and it saves much washing. In infectious illness they are invaluable. A paper bag and sanitary paper of the very soft variety is very useful if there is cough and cold with much expectoration; after use it can be placed in the bag, and the bags burnt frequently, so saving a quantity of washing. Large dinner plates may be used if no trays are available.

If short of pillows, turn up a chair at the head of the bed, or raise the head of the bed on blocks. If a feeder is not available use a cheap teapot. Use pretty crockery. Do not spoil the patient, but give plenty of sunshine, bright faces, and air. Plenty of water, inside and out, with sweet, clean rooms. Plain, simple food, well prepared and nicely given. No overflowing cup or glasses. Plenty of patience is needed.

THE CULTIVATION OF DAHLIAS.

[Miss E. Roocke, Wepowie.]

Every year increased interest is being shown in homstead gardening. There are many kinds of beautiful flowers—roses, sweet peas, carnations, poppies, dahlias, etc.—but growing dahlias has gradually increased until they have become the most popular. Dahlias excel most other flowers in their beautiful colourings, and the size of the bloom is much in advance of any other.

They are as easily grown as any other plants, and grow well in all parts of this State provided sufficient water can be given them during the growing period, and especially during flowering. The dahlia is a plant that needs much moisture, and unless it is kept growing the whole time buds may form but never fully develop. To obtain large flowers it is necessary to pinch the first buds. They can be planted out any time during November and December. In very hot districts later planting is preferable, as dahlias scorch easily; they should not flower until March or April.

Dahlias make large clusters of tubers every year. To secure best results these tubers should be divided and cut, with an eye left in each piece. The clusters of tubers should be started into growth before attempting to cut up, and if planted at once the growth continues, and the plant is through the ground in a few days. It is a good plan when planting the tubers to place in the soil a strong stake at the same time, because if the staking is left until the plant is several inches high there is a great danger of injuring the roots.

Large tubers are not necessary; a small one with a small eye will make as strong growth and as good a plant as the larger tubers. Shade is not necessary, the best flowers being obtained in the open in rather a sunny position. Too much shade means tall plants with few blooms and pale colours. Although the dahlia grows in almost any soil, a rather heavy, well-manured soil is best. As the heavy soil is not always available, lighter soils can be improved by the addition of clay and cow manure.

Deep trenches may be dug, placing in them good soil heavily manured. When first planted water sparingly, increasing the quantity as the shoots make growth. Water heavily when the first buds form, and feed the plants well with liquid manure.

Here are a few names:—Rose Grivell, White Duchess, Al. Roberts, Bill Cowan, Pink Daily Mail, Miss Adelaide, Radiant Morn, Early Jewel, Elite Glory, Grace Curling, Midnight, Amazon, and Mavis Jones. Those mentioned are the large varieties. The Cactus dahlias look very nice in vases, as they can be easily arranged. Here are some good varieties:—Violet, Grace Stewart, Frau Obracht, Mrs. A. R. Book, Charles Day, Iceberg, Bonnie Campbell, Alma Dudley, and many others. Charm dahlias:—Chris, Gold Rose, Glut, Marveen, Gala, and Sunshine.

There are so many different kinds of dahlias obtainable that if nice flowers are desired it is advisable to get the good kinds. They may be a few shillings dearer, but if a few are added each year to the list it will pay in the long run, and a nice collection of dahlias will be gradually built up.

SMALL ECONOMIES IN THE HOME.

[Mrs. B. S. McCallum, Morchard.]

This subject covers a wide range, and I intend giving a few instances whereby I am able to save on my housekeeping expenses.

The greatest economy of all is in paying cash for goods; another is to produce and preserve fruit, meat, and vegetables for home requirements. Having a small fruit garden and a preserving outfit, it is a great saving to bottle fruit for future use. I have been quite successful with peaches, apricots, plums, pears, quinces, rhubarb, and apples. I also tried fruit salad. I then experimented with meat—trying pork and beans, roast beef, roast pork, corned beef, fowl, chicken, and ham. This all proves a great help when a dinner has to be packed for the men at short notice and there is no cooked meat on hand.

As we rear our own pigs we also cure the ham and bacon required for home consumption. Having a grinder we make our own wheat meal and use it for porridge, brown bread, biscuits, &c. By way of a change rolled oats are added to wheat meal for porridge. We make our own self-raising flour, and all the butter required for home use. Some people send all the cream to the factory and buy the butter. This is much more expensive than churning for home use.

Pickles, jams, sauces, chutneys are all home made. Just a hint about plum jam. When making it take about ½gall., add a tin of raspberry jam, boil and bottle. This will give a nice supply of this delicious jam for very little outlay.

Scraps of fat and skimmings from soup and boiled meat are rendered down, strained, and used for cooking (if there is a shortage of lard and butter), but they are generally used for soap making.

Sugar bags can be used in various ways. A towel made from a sugar bag is very useful when the men folk are overhauling machinery. Aprons made from sugar bags are very handy for wear in the cowyard and when gardening. Bound with cretonne they look quite nice, and save quite a lot of extra washing. A bag for holding newspapers and a cushion for out of doors are easily made, and with a stencilled design or dyed a bright colour look quite attractive. Oven holders are also a good investment, and save burnt fingers when oven slides are being used.

Worn out frilled pillow cases yield a lot of bandages. Ends of sheets can be turned into window cleaners, or made into bags if any are needed and new calico is not on hand. Binder twine, when cut at the knot, can be plaited and then sewn in circular mat. Cut up it would make a good filling for a hassock or outdoor cushion.

Old clothes, when cut up fine with a chopper, make a nice filling for a mattress or bolster. Making hooked rugs is a very profitable way of using up old garments and stockings. Those who care to use carbonate of soda as a substitute for tooth paste will find it answers the same purpose and is more economical.

Carbolic soap, which can be procured at 1d. per cake, is in my estimation superior to any other for daily use; it prevents festering sores, and cleans and heals cuts, &c.

Making one's own frocks is a great economy. It would not pay a busy mother without help to attempt it, but where there are several women in a home it is profitable, and should be included in the home duties.

Giant cement is very useful for broken crockery. So often treasured articles are broken and seem of no more use. The mended article must be put aside for a few weeks to set, and will be as good as new.

HOME-MADE PRESERVING OUTFIT.

[Mrs. A. J. AVERY, Warcowie.]

How to make meals different from the usual routine of cooking is a much harder task on the farms these days. It is a great standby to have a few bottles of preserves where one lives out from the township and is dependent on the supply of fresh vegetables and fruit from the storekeeper. Many cannot afford to purchase a bottling outfit, but a very cheap one can be made at home, and serves the purpose just as well as an expensive one. I use any screw-top bottles that are available. Most houses have honey bottles. and as the lids for these can be purchased for 9d. per dozen they are not expensive. Preserving papers are bought at the local store 5doz. for 1s., but these papers must be placed inside the lids carefully, and only used *once*. The larger bottles are used for fruit and meat, the smaller ones for vegetables, and the smallest ones for carrots, parsnips, and celery. One of these each is sufficient for one saucepan of soup.

After buying the fruit from the greengrocer preserving can be done at a cost of 4d. per bottle; a tin of fruit cannot be sold for that price. All that is required to make an extremely useful preserving outfit is:—1 kerosene tin, 1s. 3d.; 1lb. paraffin wax; 1 wire cake cooler, 1s. 3d.; 1 thermometer, 7s. 6d.; if Fowler's bottles are used. Cut the side from the tin, and turn in all around. Next place the cake sieve in the bottom of the tin to form a platform on which to stand the bottles. Then get a piece of plain sheet tin or a piece of board and make a lid to fit the top of the tin. If using a thermometer make a hole in the top of the lid, and put the thermometer into the slit so that it will dangle in the water—the preserver is now complete.

Having prepared the fruit, vegetables, or meat put the bottles in the tin, but do not let them touch. Pour in cold water until it reaches three-quarters way up the bottles, and place the outfit on the fire. A different preserving temperature is required for different fruits, vegetables, and meats. Sterilise everything at the given temperature for 2¼ hours. When the bottles are cold dip them below the lids into a tin of hot paraffin wax to make sure that they are airtight; that is the main point about the preserving.

RECIPES.

Tomato Soup.—1 bottle tomatoes, ½ cup lentils or split peas, 1 onion, 6 leaves mint (if liked), ½ cup milk (more if liked), 2 dessertspoons flour. *Method*: Place onion and lentils on fire with water, salt, and pepper to cook; then rub tomatoes through a wire sieve if not skinned before bottling. Add these to the onion and lentils, then mix the flour and milk, and add this to the above. Boil all together for 5 minutes, and it is ready for use.

Vegetable Soup.—Stock, water, salt and pepper to taste, 1 onion, 1 small bottle carrots and celery, 1 potato, and a few sticks of macaroni. *Method*: Boil onion, potato, and macaroni in stock until cooked, then add bottles of vegetables; boil all together, and the soup is ready to eat.

Mince-meat Curry.—1 bottle of mince-meat, 1 onion, pepper and salt, 1 apple. *Method*: When boiling add a little curry and a small bottle of carrots, and this for the table.

Others papers including "Uses of the Lemon," Mrs. L. Pascoe (Wepowie), and "Etiquette at Sport," Mrs. H. Noske (Wepowie), were read and discussed.

SUMMARY OF OTHER REPORTS RECEIVED.

Branch.	Date of Meeting.	Attendance.	Subject.	Secretary.
			WOMEN'S BRANCHES.	
Karte	6/5/36	34	Combined Meeting—Discussion	Mrs. F. N. Atze
Coonawarra	27/5/36	28	Butter Competition	Miss O. A. Lear
Clare	2/5/36	16	Dried Fruit Recipes	Mrs. A. C. Pollock
Auburn	29/5/36	26	" Rug Making "—Mesdames Blatchford and Jones	Miss L. J. Dennison
Saddleworth	2/6/36	15	Discussion—Centenary Arrangements	Miss G. E. Frost
Sheoak Log	4/6/36	29	Papers by Members	Miss K. M. Koch
Hope Forest	4/6/36	10	Hints and Questions	Miss M. E. De Caux
Coonalpyn	3/6/36	17	Election of Officers. Arts and Crafts Display	Miss E. E. George
McLaren Flat	4/6/36	—	" Flowers "—Mrs. S. Elliott	Mrs. B. Powell
Parilla	27/5/36	21	Discussion	Mrs. A. W. Welden
Kybybolite	12/5/36	21	Conference Report	Mrs. W. D. Kekwick
Rendelsham	3/6/36	22	Pruning. Bring a Gift and Buy a Gift	Mrs. W. Bignell
